Subclavian. On the right ſide, ſeparates from the carotid artery, and paſſing on nearly at a right angle, ſends off the inferior thyroid, or inferior guttural artery; this aſcending on the ſide of the neck, gives branches to the œſophagus and trachea arteria; then entering the lower part of the thyroid gland, communicates largely with the thyroidea ſuperior; the ſubclavian paſſing on a little further, gives off a large artery, called vertebralis, which, aſcending through the canal formed by the holes in the tranſverſe proceſſes of the vertebræ colli, enters the foramen magnum occipitale. On the cuneiform proceſs of the os occipitis, the two vertebral arteries uniting, form the baſilary artery. The ſubclavian paſſing between the heads of the ſcalenus muſcle, ſends off ſome branches to the muſcles of the neck, from whence running on towards the arm, and lying between the clavicle and firſt rib, it is lodged in a furrow on the upper part of that rib, and entering the axillary cavity, takes the name of axillary artery; whilſt in the axilla, it ſends off a branch to the upper part of the ſcapula, called ſcapulary artery; there are three or four branches, called thoracic or external mammary; theſe ſupply ſome of the muſcles on the ſide of the trunk in men, and the breaſts in women; a large branch paſſing near the inferior coſta ſcapulæ, is called inferior ſcapulary; the trunk of the artery being ſeated near the head of the os brachii, ſends off a branch which, ſurrounding the upper extremity of the os brachii, ſupplies with blood the deltoid, and parts about the joint; this artery paſſing below the fold of the axilla, is called brachial, lying on the inſide of the arm, ſends off branches to the ſkin and muſcles of the arm; beſides theſe, are three branches, called anaſtamoſing arteries, which communicate with branches, that are reflected from the arteries ſeated below the joint of the cubit; the ſuperior ariſes from the upper part of the brachial artery; the ſecond, called circumflexa, near the middle of the arm; the third, about an inch and a half above the joint of the cubit. The brachial artery paſſing from the arm to the fore-arm, lies on the inſide of the joint, and is covered by the faſcia of the biceps muſcle; about an inch below the joint of the cubit, it ſends off a large artery, called radial; then deſcending a little further, and becoming deep-ſeated under the muſcles on the inner ſide of the fore arm, it divides into branches; the larger called ulnar, the ſmaller, interoſſeous.

The radial reflects an artery immediately below the joint of the cubit, which ſupplies the parts of the joint with blood, and anaſtamoſes the circumflexa. The upper part of the artery lies on the fore part of the radius, and is covered by muſcles; deſcending, becomes more ſuperficial; near the joint of the carpus, ſends a branch into the palm of the hand, ſupplying the thumb; then paſſing under the tendons of the extenſor muſcles of the thumb, gives off branches to the back of the hand; the remaining part of this artery enters the palm, between the metacarpal bone ſuſtaining the index and the firſt bone of the thumb, where it ſupplies the interoſſei muſcles, &c. and communicates with the branches of the ulnar artery.

The ulnar artery, like the radial, reflects a branch to the inner condyle of the arm, which anaſtamoſes with the inferior branch of the brachial artery; at its upper part, is covered by muſcles; near the wriſt, becomes ſuperficial; paſſing over the annular ligament of the carpus, enters the palm of the hand, and ſends a branch to each ſide of each finger: theſe branches anaſtamoſe frequently with the branches of the radial artery.

The interoſſeous artery, lies upon the interoſſeous ligament, ſupplying the deep-ſeated muſcles on the fore arm; paſſing through a hole in the lower part of the interoſſeous ligament, ſupplies the ſkin and muſcles on the back of the hand.

The ſubclavian artery, before it enters between the heads of the ſcalenus muſcle, ſends down a branch to the internal part of the thorax, called internal thoracic, or mammary; deſcending on the inner ſide of the ſternum, ſends branches to the anterior part of the intercoſtal ſpaces; theſe anaſtamoſe with the anterior branches of the intercoſtal arteries; ſends branches to the anterior mediaſtinum, to the pericardium, and ſome large branches to the breaſt in the female, and to the integuments of the cheſt, in the male; theſe anaſtamoſe with the external thoracics, the remaining branches paſs down, on the fourth part of the abdominal muſcles, and communicate with ſome branches from the epigaſtric.

The Aorta having formed its curvature, paſſes obliquely to the left ſide of the cheſt, and deſcending on the left of the ſpine, forms what is called aorta deſcendens; this, whilſt in the cheſt, ſends off from the fore part, two or three ſmall branches to the œſophagus, called œſophagæal; theſe carry blood to the œſophagus; alſo, a branch to each lung, named broncheal, and a few very ſmall branches to the poſterior mediaſtinal ſpace; from the lateral parts of the aorta, the intercoſtal arteries (ten pairs in number) ariſe; they run, at the ſuperior part of each intercoſtal ſpace, in a furrow made in the inferior edge of each rib; as they approach the ſternum, they branch irregularly, being ſometimes at the lower part of the intercoſtal ſpace; the anterior branches anaſtamoſe with the branches of the mammary, and thoſe of the external thoracic arteries; the intercoſtal arteries ſupply with blood the ſpaces between the ribs, ſend branches to the pleura, and others to the muſcles and integuments ſituate on the outer parts of the cheſt. The aorto, whilſt in the thorax, ſends alſo ſome branches into the theca vertebralis, to the ſpinal marrow, &c. The aorta, as it deſcends, gets nearer to the fore part of the ſpine, and paſſing between the two cruræ of the diaphragm, enters the cavity of the abdomen; it there ſends off many large branches, ſome in pairs, and others which have no fellows, and, for this reaſon, are called azygos.

The azygos arteries, are three in number, diſtributed to the chylopoetic viſcera; the firſt, is called Cæliac, ariſes from the fore part of the trunk of the aorto, where it paſſes through, between the two cruræ of the diaphragm: divides into there branches; firſt, the coronary, is diſtributed to the leſſer curvature of the ſtomach; ſecond, the hepatic, runs towards the liver, and divides into two branches, one of which goes to each lobe of the liver: in its paſſage, the hepatic ſends off the pylorica, a branch which goes to the pylorus; the gaſtrica dextra, going to the greater curvature of the ſtomach; the duodenales ſmall branches going to the duodenum, and, laſtly, a branch going to the gall bladder. Third, the ſplenic, is lodged in a ſulcus of the pancreas, and ſupplies it with blood; thence paſſing into the left hypochondrium, divides into ſeveral branches which enter the ſinuoſity of the ſpleen; the ſplenic artery, in its paſſage, gives off four branches to the greater curvature of the ſtomach, called vaſa brevia; the laſt being near the left extremity of the ſtomach, is called gaſtrica ſiniſtra. *Note, All the arteries of the ſtomach anaſtamoſe with each other*.

The omentum receives many ſmall branches from the cœliac; thoſe on the right ſide, ariſe from the gaſtrica dextra; thoſe on the left, from the ſplenic; on the right are called gaſtro-epiploicæ dextræ; ſiniſtræ, on the left.

Meſenterica ſuperior is principally diſtributed to the ſmall inteſtines; on the left ſide, ſends up a branch to the tranſverſe arch of the colon, which is called colica ſiniſtra.

Meſenterica inferior, ſends branches to the lower part of the inteſtinal canal; a large branch to the caput coli, called colica dextra; this aſcending anaſtamoſes with the colica ſiniſtra; ſends branches to the rectum, called hæmorrhoidal. *Note, The two meſenteric arteries anaſtamoſe frequently with euch other*; they ſupply the large and ſmall inteſtines with blood. Phrenic arteries, ſent off by the aorta in the abdomen, are reflected to the under ſurface of the diaphragm, ſupplying it with blood,

Capſular arteries, are diſtributed to the renal capſulæ.

Emulgents, carry blood to the kidnies, for the ſecretion of urine.

Spermatics, ariſe below the emulgents, and commonly from the fore part of the aorta; go to the teſticles in the male; to the ovaria in the female.

Vertebral, are three or four pairs in number, ſend branches to the loins, to the extenſor muſcles of the ſpine, and to the lateral parts of the parietes of the abdomen.

The aorta, deſcending as low as the body of the fourth lumbar vertebra, divides into two branches, called iliac; this part commonly called bifurcation of the aorta; the iliacs paſſing on the inner ſide of the pſoas muſcles, each divides into two branches, the one internal, the other external; the internal iliac paſſing over the brim of the pelvis, gives branches to the bladder, called veſicales; branches to the proſtrate gland and veſicula ſeminales; branches to the muſcles on the internal part of the pelvis, and to the external part of the anus. Alſo a branch, which accompanying the obturator nerve, is diſtributed to the adductors of the thigh, called obturator artery. The trunk, paſſing through the foramen magnum iſchii, ſends off the glutæa to the glutæi muſcles and ſkin of the nates. Alſo ſends off a large branch, which accompanies the ſciatic nerves and anaſtamoſes with the branches of the profundæ. The arteriæ pudicæ runing on the inſide of the tuberoſities of the iſchium, enter the crura penis and carry blood for the erection of the penis. The external iliac, running on the fore part of the pſoas muſcle, at the lower part of the abdomen, juſt before it paſſes under Poupart's ligament, ſends off two branches. Firſt, Ilio-lumbalis, paſſing on the inſide of the ſpine of the ilium, ſends ſmall branches to the iliacus internus and pſoas muſcles; and anaſtamoſes with the vertebral arteries in the loins. Second, Epigaſtric, is reflected to the abdominal muſcles; and aſcending on the inner ſide of the rectus abdominis, ſends branches to the neighbouring parts, which anaſtamoſe with branches from the mammary. The trunk having paſſed under Poupart's ligament into the thigh, ſends off many ſmall muſcular branches to the muſcles ſeated on the thigh; alſo a large branch, which becoming deep-ſeated, goes to the joint of the thigh and muſcles ſurrounding it. A large branch, called profunda, conveying blood to the muſcles on the back part of the thigh, and anaſtamoſing with ſome branches of the internal iliac. The artery paſſing obliquely round the inner ſide of the thigh, gets into the ham, where it takes the name popliteal, entering the leg between the two heads of the gaſtrocnemius divides into three branches, the firſt paſſing through a hole in the interoſſeous ligament, comes on the outer ſide of the tibia, and deſcending on the fore part of the leg, is called tibialis antica, paſſing under the annular ligament of the tarſus, ſends a branch to the upper part of the foot, and one to the great toe; the trunk running between the bones of the tarſus, gets into the ſole of the foot, gives branches to the deep ſeated muſcles, and anaſtamoſes with the tibialis poſtica.

Tibialis poſtica; the ſecond branch, running on the poſterior part of the tibia, gives branches to the muſcles on the back part of the leg, paſſing under the maleolus internus, gets into the calcaneum, and running under the faſcia of the foot, ſends branches to the ſkin, on the under ſide of the foot, and two branches to each toe. This artery makes frequent communications with the tibialis antica. Peronea or interoſſea, is the third branch, paſſing on the inner of the perona, ſends branches to the muſcles and ſkin on the outer ſide of the leg, running on to the maleolus externus, ſends branches to the outer ſide of the foot.

Explanation to the PLATE *of* ARTERIES.

THE HEART, NECK, AND HEAD.

A, Right auricle of the heart. B, Left auricle. C, The ventricles of the heart, with the coronary arteries and veins. D, Pulmonary artery. E, Aorta aſcendens. F, Arch of aorta. N. B. Almoſt all the arteries go off in pairs, ſo that a deſcription of one ſide of the body is ſufficient.

SECT. II.

VEINS.

Veins in the human body are ſix in number, which terminate in the heart, viz. cava ſuperior, cava inferior, and four pulmonary veins.

The blood carried from the left ventricle of the heart by the aorta, having performed the offices of nutrition, vivification, and ſecretion, is returned to the right auricle by the two cavæ. The blood carried from the heart by the branches of the aorta, above the diaphragm, is returned by the branches of the cava ſuperior; that below the diaphragm, by the cava inferior.

When we trace the veins phyſiologically, we begin at the extreme parts of the body, but the beſt method for ſtudents, is to trace them anatomically, like the arteries, viz. from trunk to branch.

The cava ſuperior aſcending from the heart, whilſt in the cheſt, receives branches from the thymus gland, called venæ thymicæ; ſmall branches on the fore part, from the anterior mediaſtinal ſpace; receives the vena azygos, on its back part, returning the blood carried to the parts of the cheſt, by the intercoſtal arteries; alſo the internal thoracic vein attending on the mammary artery. At the upper part of the cheſt, the cava divides into two branches, called ſubclavians; that on the right ſide ſhort; that on the left long. The left ſubclavian croſſes the cheſt on the fore part of the large veſſels ariſing from the curvature of the aorta. The two ſubclavians have ſimilar diſtributions; each one aſcending on the ſide of neck, forms the internal or deep-ſeated jugular, paſſing on the outer ſide of the carotid artery. Near the angle of the lower jaw, the internal jugular receives branches from the thyroid gland; alſo ſeveral ſmall branches from the muſcles on the neck; it then divides into branches, which accompany all the branches of the external carotid, except thoſe that go to the face and ſide of the head; and entering the thimble-like cavity in the baſis of the ſkull, forms the ſinuſes of the dura mater, which receive the blood carried to the brain by the internal carotid. Oppoſite to the firſt bone of the ſternum, the left ſubclavian receives three or four ſmall branches from the lower part of the thyroid gland and muſcles on the fore part of the neck.

The ſubclavian paſſing towards the ſcalenus, ſends off the external jugular, which aſcending obliquely on the ſide of the neck, lies ſuperficial under the platyſma myhoides; receives many ſmall branches from the ſkin of the neck, near the angle of the jaw; alſo the temporal vein returning the blood from the temporal artery, then paſſing over the baſis of the jaw, accompanies the facial

artery, ſending branches to the different parts of the face, which receive the ſame names as are given to the arteries, to which they correſpond. The angular vein enters the orbit, and communicates with branches from the internal part of the ſkull. The external jugular frequently communicates with the internal, near the angle of the jaw; in theſe inſtances the external one is wanting on the neck. The ſubclavian paſſing on, towards the arm receives a large vein which ordinarily attends on the vertebral artery; alſo ſeveral ſmall branches from the muſcles and ſkin on the back of the neck; then paſſing between the heads of the ſcalenus, it accompanies the artery to the arm, between the clavicle and firſt rib, it is placed on the inner ſide next the ſternum; juſt before it paſſes under the clavicle, it receives the cephalic vein which running between the pectoral and deltoid muſcles, paſſes on the outer part of the biceps flexor cubiti, and gets to the joint of the cubit, where it communicates with branches which come from the fore-arm. The veins in the extremities are larger and more numerous than the arteries, and are divided into two ſets; one lying immediately under the ſkin, called ſuperficial; the other deep ſeated, accompanying the branches of the artery; in general two veins attend on each arterial branch: theſe veins take the ſame names that are given to the arteries they accompany. The axillary vein receives the external thoracic and ſuperior ſcapulary veins; deſcending on the inner ſide of the biceps flexor receives many muſcular and ſmall cutaneous branches. A little above the joint of the cubit, receives the ſuperficial vein from the fore arm. The trunk paſſing under the faſcia of the biceps becomes deep ſeated, and attends the radial, ulnar and interoſſeal arteries. The ſuperficial veins from the fore arm, at the joint of the cubit, form three branches, which communicate with each other; thoſe from the back and outer part make the cephalic; thoſe on the fore part, the median; and thoſe on the inner ſide form the baſilic; all thoſe are ſuperficial at the joint of the cubit, and the two latter open in the deep ſeated vein, a little above the joint. The vein coming from the little finger is called vena ſalvatella.

Vena cava inferior paſſes through the centrum tendinoſum of the diaphragm, is lodged in the ſulcus of the liver, receives from the liver the venæ cavæ hepaticæ; and paſſing down on the right of the ſpine receives branches, in the following order: the phrenic veins from the diaphragm; capſular veins from the renal capſulæ; emulgent veins from the kidneys; the right ſpermatic vein, and three or four ſmall vertebral veins. *Note, The veins coming from the left ſide of the ſpine are longer than thoſe on the right.* The cava attending the aorta at its bifurcation, divides into two iliacs; each iliac is divided into external and internal: the internal paſſing over the brim of the pelvis, divides into branches which attend on the branches of the internal iliac artery, and receives the ſame names applied to the arteries they accompany. The veins of the penis are two in number, one deep ſeated in dorſo penis, placed in a ſulcus between the corpora cavernoſa, and called vena magna ipſius penis; the other ſuperficial, belonging to the integuments, called vena tegmentorum; the two communicate near the ſymphiſis pubis, under which they paſs and open into the veins of the bladder. The external iliac vein, paſſing on the inner ſide of the artery, runs under Poupart's ligament into the thigh. On the inner ſide, it receives the trunk of the ſuperficial veins of the leg and foot, this called vena ſaphena, ſeated on the inſide of the knee. The deep ſeated vein accompanies the artery to all parts of the lower extremity

For the peculiarities in the female, ſee female organs of generation.

Vena portarum, is a vein peculiar to the viſcera, and formed in the following manner: the three azygos arteries having ſupplied the chylopoetic viſcera with blood for the purpoſes of ſecretion, &c. that blood is returned by branches of veins, which every where accompany the arteries, except the hepatic branch; all theſe veins unite and form a large trunk, which, inſtead of opening into the cava inferior like other veins, paſſes on to the liver, and enters its ſubſtance, at the part called portæ. (from whence this vein takes its name;) then dividing into branches ramifies to all parts of the liver, carrying blood to it for the purpoſe of ſecretion, and is, ex officio, an artery. The blood carried to the liver both by the arteria hepatica for nutrition, and by the vena portarum for ſecretion, is returned into the cava inferior, by three large and two or three ſmall veins, called venæ cavæ hepaticæ; theſe pour their blood into the cava inferior, whilſt it lies in a ſulcus of the liver, or juſt before it paſſes through the centrum tendinoſum of the diaphragm to open into the heart.

The veins of the heart, called coronary, open into the right auricle.

SECT. III.

COURSE AND DISTRIBUTION OF THE ABSORBENT SYSTEM.

Whoever carefully views the Abſorbent Syſtem, muſt be convinced, that as it explains, and points out the cure of many diſeaſes, it deſerves the attention of the practitioners of the healing art. And as it is ſo generally diffuſed through the animal kingdom, it ſtrongly claims the regard of thoſe who wiſh to enquire philoſophically into the animal œconomy. I have in this Section introduced Six Repreſentations, and have added to them copious deſcriptions, which with what is inſerted under General Obſervations, (in Part I. Sect. V.) *will ſufficiently illuſtrate the Syſtem of Abſorbents.*

Explanation of the PLATE *on the* ABSORBENT VESSELS.

At this place thoſe veſſels paſs to the fore part of the groin, where they communicate with the ſupercial lymphatic veſſels. n, A part of the ſuperficial lymphatic veſſels appearing on the brim of the pelvis.

PART V.

SPLANCHNOLOGY,

OR A DESCRIPTION OF THE VISCERA AND FEMALE ORGANS OF GENERATION.

SECT. I.

OF THE ABDOMEN.

THE abdomen, or lower belly, extends from the lower extremity of the ſternum, or the hollow, uſually called the pit of the ſtomach, and more properly *ſcrobiculus cordis*, to the lower part of the trunk.

It is diſtinguiſhed into three diviſions called *regions*; of theſe the upper one, which is called the *epigaſtric region*, begins immediately under the ſternum, and extends to within four fingers breadth of the navel, where the middle or *umbilical region* begins, and reaches to the ſame diſtance below the navel. The third, which is called the *hypogaſtric*, includes the reſt of the abdomen, as far as the os pubis.

Each of the regions is ſubdivided into three others; two of which compoſe the ſides, and the other the middle part of each region.

The middle part of the upper region is called *epigaſtrium*, and its two ſides *hypochondria*. The middle part of the next region is the umbilical region, properly ſo called, and its two ſides are the flanks, or iliac regions. Laſtly, the middle part of the lower region retains the name of hypogaſtrium, and its ſides are called inguina or groins. The back part of the abdomen bears the name of lumbar region.

After having removed the ſkin, adipoſe membrane, and abdominal muſcles, we diſcover the peritonæum or membrane that envelopes all the viſcera of the lower belly. This being opened, the firſt part that preſents itſelf is the omention or cawl, floating on the ſurface of the inteſtines, which are likewiſe ſeen every where looſe and moiſt, and making a great number of circumvolutions through the whole cavity of the abdomen. The ſtomach is placed in the epigaſtrium, and under the ſtomach is the pancreas. The liver fills the right hypochondrium, and the ſpleen is ſituated in the left. The kidneys are ſeen about the middle of the lumbar region, and the urinary bladder and parts of generation are ſeated in the lower diviſion of the belly.

SECT II.

OF THE PERITONÆUM.

The peritonæum is a ſtrong ſimple membrane, by which all the viſcera of the abdomen are ſurrounded, and in ſome meaſure ſupported. Many anatomical writers, particularly Winſlow, have deſcribed it as being compoſed of two diſtinct membranous laminæ; but their deſcription ſeems to be erroneous. What perhaps appeared to be a ſecond lamina, being found to be ſimply a cellular coat, which ſends off productions to the blood-veſſels paſſing out of the abdominal cavity. The aorta and vena caav likewiſe derive a covering from the ſame membrane, which ſeems to be a part of the cellular membrane we have already deſcribed.

The peritonæum, by its productions and reduplications, envelopes the greateſt part of the abdominal viſcera. It is ſoft, and capable of conſiderable extenſion; and is kept ſmooth and moiſt by a vapour, which is conſtantly exhaling from its inner ſurface, and is returned again into the circulation by the abſorbents.

This moiſture not only contributes to the ſoftneſs of the peritonæum, but prevents the attrition, and other ill effects which would otherwiſe probably be occaſioned, by the motion of the viſcera upon each other.

When this fluid is ſupplied in too great a quantity, or the abſorbents become incapable of carrying it off, it accumulates, and conſtitutes an aſcites or dropſy of the belly; and when by any means the exhalation is diſcontinued, the peritonæum thickens, becomes diſeaſed, and the viſcera are ſometimes found adhering to each other.

The peritonæum is not a very vaſcular membrane. In a ſound ſtate it ſeems to be endued with little or no feeling, and the nerves that paſs through it appear to belong to the abdominal muſcles.

SECT. III.

OF THE OMENTUM.

The omentum, epiploon, or cawl, is a double membrane, produced from the peritonæum. It is interlarded with fat, and adheres to the ſtomach, ſpleen, duodenum, and colon: from thence hanging down looſe, and floating on the ſurface of the inteſtines. Its ſize is different in different ſubjects. In ſome it deſcends as low as the pelvis, and it is commonly longer at the left ſide than the right.

The omentum derives its arteries from the ſplenic and hepatic. Its veins terminate in the vena portæ. Its nerves, which are very few, come from the ſplenic and hepatic plexus.

The omentum parvum begins at the upper part of the duodenum, extends along the leſſer curvature of the ſtomach as far as the œſophagus, and terminates about the neck of the gall-bladder, and behind the left ligament of the liver, ſo that it covers the leſſer lobe; near the beginning of which we may obſerve a ſmall opening, firſt deſcribed by Winſlow, through which the whole pouch may eaſily be diſtended with air. The veſſels of the omentum parvum are derived chiefly from the coronary ſtomachic arteries and veins.

The uſes of the omentum are not yet ſatisfactorily determined. Perhaps by its ſoftneſs and looſeneſs it may ſerve to prevent thoſe adheſions of the abdominal viſcera, which have been found to take place when the fat of the omentum has been much waſted. Some authors have ſuppoſed, that it aſſiſts in the preparation of bile; but this idea is founded merely on conjecture.

SECT. IV.

OF THE OESOPHAGUS.

THE œſophagus or gullet is a membranous and muſcular canal, extending from the bottom of the mouth to the upper orifice of the ſtomach. Its upper part, where the aliment is received is ſhaped ſomewhat like a funnel, and is called the *pharynx*.

From hence it runs down cloſe to the bodies of the vertebræ as far as the diaphragm, in which there is an opening through which it paſſes, and then terminates in the ſtomach about the eleventh or twelfth vertebra of the back.

The œſophagus is plentifully ſupplied with arteries from the external carotid, bronchial, and ſuperior intercoſtal arteries; its veins empty themſelves into the vena azygos, internal jugular, and mammary veins, &c.

Its nerves are derived chiefly from the eighth pair.

We likewiſe meet with a mucus in the œſophagus, which every where lubricates its inner ſurface, and tends to aſſiſt in deglutition. This mucus ſeems to be ſecreted by very minute glands, like the mucus in other parts of the alimentary canal.

SECT. V.

OF THE STOMACH.

THE Stomach is a membranous and muſcular bag, in ſhape not unlike a bagpipe, lying acroſs the upper part of the abdomen, and inclining rather more to the left than the right ſide.

It has two orifices, one of which receives the end of the œſophagus, and is called the *cardia*, and ſometimes the left and upper orifice of the ſtomach; though its ſituation is not much higher than the other, which is ſtyled the right and inferior orifice, and more commonly the *pylorus*; both theſe openings are more elevated than the body of the Stomach.

The aliment paſſes down the œſophagus into the Stomach, through the cardia; and after having undergone the neceſſary digeſtion, paſſes out at the pylorus, where the inteſtinal canal commences.

The Stomach is compoſed of four tunics or coats, which are ſo intimately connected together, that it requires no little dexterity in the anatomiſt to demonſtrate them. The exterior one is membranous, being derived from the peritonæum. The ſecond is a muſcular tunic, compoſed of fleſhy fibres, which are in the greateſt number about the two orifices. The third is called the nervous coat, and within this is the villous or velvet-like coat which compoſes the inſide of the Stomach.

The two laſt coats being more extenſive than the two firſt, form the folds, which are obſerved every where in the cavity of this viſcus, and more particularly about the pylorus; where they ſeem to impede the too haſty excluſion of the aliment, making a conſiderable plait, called *valvula pylori*.

The inner coat is conſtantly moiſtened by a mucus, which approaches to the nature of the ſaliva, and is called the gaſtric juice; this liquor has been ſuppoſed to be ſecreted by certain minute glands, ſeated in the nervous tunic, whoſe excretory ducts open on the ſurface of the villous coat.

The arteries of the ſtomach called the gaſtric arteries are principally derived from the cæliac; ſome of its veins paſs to the ſplenic, and others to the vena portæ; and its nerves are chiefly from the eighth pair or par vagum.

The account given of the tunics of the ſtomach may be applied to the whole alimentary canal; for both the œſophagus and inteſtines are, like this viſcus, compoſed of four coats.

Before we deſcribe the courſe of the aliment and the uſes of the ſtomach, it will be neceſſary to ſpeak of other parts which aſſiſt in the proceſs of digeſtion.

SECT. VI.

OF THE INTESTINES.

THE Inteſtines form a canal, which is uſually ſix times longer than the body to which it belongs. This canal extends from the pylorus, or inferior orifice of the ſtomach, to the anus.

It will be eaſily underſtood, that a part of ſuch great length muſt neceſſarily make many circumvolutions, to be confined with ſo many other viſcera within the cavity of the lower belly.

Although the Inteſtines are in fact, as we have obſerved, only one long and extenſive canal, yet different parts have been diſtinguiſhed by different names. The Inteſtines are firſt diſtinguiſhed into two parts, one of which begins at the ſtomach, and is called the *ſmall Inteſtines*, from the ſmall ſize of the canal, when compared with the other part, which is called the *large Inteſtines*, and includes the lower portion of the canal down to the anus.

Each of theſe parts has its ſubdiviſions. The ſmall Inteſtines being diſtinguiſhed into duodenum, jejunum, and ileum, and the larger portion into cœcum, colon, and rectum.

The ſmall Inteſtines fill the middle and fore parts of the belly, while the large Inteſtines fill the ſides and both the upper and lower parts of the cavity.

The duodenum, which is the firſt of the ſmall Inteſtines, is ſo called, becauſe it is about 12 inches long. It begins at the pylorus and terminates in the jejunum, which is a part of the canal obſerved to be uſually more empty than the other Inteſtines. This appearance gives it its name, and likewiſe ſerves to point out where it begins.

The next diviſion is the ileum, which of itſelf exceeds the united length of the duodenum and jejunum, and has received its name from its numerous circumvolutions. The large circumvolution of the ileum covers the firſt of the large Inteſtines called the *cæcum* which ſeems properly to belong to the colon, being a kind of pouch of about four fingers in width, and nearly of the ſame length, having exteriorly a little appendix, called *appendix cæci*.

The cœcum is placed in the cavity of the os ilium on the right ſide, and terminates in the colon, which is the largeſt of all the Inteſtines.

This Inteſtine aſcends by the right kidney to which it is attached, paſſes under the hollow part of the liver, and the bottom of the ſtomach to the ſpleen, to which it is likewiſe ſecured, as it is alſo to the left kidney; and from thence paſſes down towards the os ſacrum, where, from its ſtrait courſe, the canal begins to take the name of rectum, which terminates at the anus.

There are three ligamentous bands extending through the whole length of the colon, which by being ſhorter than its too inner coats, ſerve to increaſe the plaits on the inner ſurface of this gut.

It has been already obſerved, that the Inteſtinal canal is compoſed of four tunics; but it remains to be remarked, that here, as in the ſtomach, the two inner tunics being more extenſive than the other two, form the plaits which are to be ſeen in the inner ſurface of the Inteſtines, and are called *valvulæ conniventes*; which from the inequalities they occaſion in the canal are ſufficient to retard in ſome meaſure the progreſſive motion of the fæces, and to afford a greater ſurface for the abſorption of chyle, and their natural poſition ſeems to oppoſe itſelf to the return of the aliment.

Beſides theſe *valvulæ conniventes*, there is one more conſiderable than the reſt, called the *valve of the colon*; which is found at that at that part of the canal where the Inteſtinum ileum is joined to the colon. This valve permits the alimentary pulp to paſs downwards, but ſerves to prevent its return upwards; and it is by this valve, that glyſters are prevented from paſſing into the ſmall Inteſtines.

Of the little vermiform appendix of the cœcum, it will be ſufficient to ſay, that its uſes have never yet been aſcertained. In birds we meet with two of theſe appendices.

The Inteſtines are lubricated by a conſtant ſupply of mucus, which is probably ſecreted by very minute follicles. This mucus promotes the deſcent of the alimentary pulp, and in ſome meaſure defends the inner ſurface of the Inteſtines from the irritation to which it would, perhaps, otherwiſe be continually expoſed from the aliment.

The arteries of the Inteſtines are continuations of the meſenteric arteries, which are derived in two conſiderable branches from the aorta. The redundant blood is carried back into the vena portarum.

In the rectum the veins are called *hemorrhoidal*, and are there diſtinguiſhed into internal and external: the firſt are branches of the inferior meſenteric vein, but the latter paſs into other veins. Sometimes theſe veins are diſtended with blood from obſtructions, from weakneſs of their coats, or from other cauſes, and what we call the *hæmorrhoids* takes place. In this diſeaſe they are ſometimes ruptured; and the diſcharge of blood which conſequently follows, has probably occaſioned them to be called *hæmorrhoidal veins*.

The nerves of the Inteſtines are derived from the eighth pair.

SECT. VII.

OF THE MESENTERY, AND MESOCOLON.

THE name of the Meſentery implies its ſituation amidſt the inteſtines. It is in fact a part of the peritonæum, being a reduplication of that membrane from each ſide of the lumbar vertebræ, to which it is firmly attached, ſo that it is formed of two laminæ, connected to each other by cellular membrane.

The inteſtines, in their different circumvolutions, form a great number of arches, and the Meſentery accompanies them through all theſe turns; but by being attached only to the hollow part of each arch, it is found to have only a third of the extent of the inteſtines.

That part of this membrane which accompanies the ſmall inteſtines is the *Meſentery*, properly ſo called; but thoſe parts of it which are attached to the colon and rectum are diſtinguiſhed by the names of *meſo-colon* and *meſo-rectum*.

There are many conglobate glands diſperſed through this double membrane, through which the lacteals and lymphatics paſs in their way to the thoracic duct. The blood-veſſels of the Meſentery were deſcribed in ſpeaking of the inteſtines.

This membrane, by its attachment to the vertebræ, ſerves to keep the inteſtines in their natural ſituation. The idea uſually formed of the colic called *miſerere*, is perfectly erroneous; it being impoſſible that the inteſtines can be twiſted, as many ſuppoſe they are, in that diſeaſe, their attachment to the Meſentery effectually preventing ſuch an accident; but a diſarrangement ſometimes takes place in the inteſtinal canal itſelf, which is productive of diſagreeable and ſometimes fatal conſequences. This is by an introſuſpection of the inteſtine, an idea of which may be eaſily formed, by taking the finger of a glove, and involving one part of it within the other.

SECT. VIII.

OF THE PANCREAS.

THE Pancreas is a conglomerate gland, placed behind the bottom of the ſtomach, towards the firſt vertebra of the loins; ſhaped like a dog's tongue, with its point ſtretched out towards the ſpleen, and its other end extending towards the duodunum. It is about eight fingers breadth in length, two or three in width, and one in thickneſs.

This viſcus, which is of a yellowiſh colour, ſomewhat inclined to red, is covered with a membrane which it derives from the peritoneum. Its arteries, which are rather numerous than large, are derived chiefly from the ſplenic and hepatic, and its veins paſs into the veins of the ſame name. Its nerves are derived from the intercoſtal.

The many little glands of which it has been obſerved the Pancreas is compoſed, all ſerve to ſecrete a liquor called the *Pancreatic juice*, which in its colour, conſiſtence, and other properties, does not ſeem to differ from the ſaliva. Each of theſe glands ſends out a little excretory duct, which uniting with others, help to form larger ducts; and all theſe at laſt terminate in one common excretory duct which runs through the middle of the gland, and is now uſually called *ductus pancreaticus*. This canal opens into the inteſtinum duodenum; ſometimes by the ſame orifice with the biliary duct, and ſometimes by a diſtinct opening. The liquor it diſcharges being of a mild and inſipid nature, ſerves to dilute the alimentary pulp, and to incorporate it more eaſily with the bile.

SECT. IX.

OF THE LIVER AND GALL BLADDER.

THE Liver is a viſcus of conſiderable ſize, and of a reddiſh colour; convex ſuperiorly and anteriorly, where it is placed under the ribs and diaphragm, and of an unequal ſurface poſteriorly. It is chiefly ſituated in the right hypochondrium, and under the falſe ribs; but it likewiſe extends into the epigaſtric region, where it borders upon the ſtomach. It is covered by a production of the peritoneum, which ſerves to attach it by three of its reduplications to the falſe ribs. Theſe reduplications are called *ligaments*, though very different in its texture from what are called by the ſame name in other parts of the body. The umbilical cord, too, which in the fœtus is pervious, gradually becomes a ſimple ligament after birth; and by paſſing to the Liver, ſerves likewiſe to ſecure it in its ſituation.

At the poſterior part of this organ, where the umbilical veſſels enter, it is found divided into three lobes. Of theſe, the largeſt is placed in the right hypocondrium; the other, which covers part of the ſtomach, is called the lite lobe; and the third is called Lobulus Spigelii. All the veſſels, which go to the Liver, paſs in at the fiſſure we have mentioned; and the production of the peritoneum, which inveſts the Liver, was deſcribed by Gliſſon, an Engliſh anatomiſt, as accompanying them in their paſſage, and ſurrounding them like a glove; hence this production has been commonly known by the name of *capſula of Gliſſon*: but it appears to be chiefly a continuation of the cellular membrane, which covers the vena portæ ventralis.

The Liver was conſidered by the ancients as an organ deſtined to prepare and perfect the blood; but later diſcoveries have proved that this opinion was wrong, and that the Liver is a glandular ſubſtance, formed for the ſecretion of the bile.

The blood is conveyed to the Liver by the hepatic artery, and the vena portæ. This is contrary to the mode of circulation in other parts, where veins only ſerve to carry off the redundant blood: but in this viſcus the hepatic artery, which is derived from the cæliac, is principally deſtined for its nouriſhment; and the vena portæ, which is formed by the union of the veins from moſt of the abdominal viſcera, furniſhes the blood, from which the bile is chiefly to be ſeparated: ſo that theſe two ſeries of veſſels ſerve very diſtinct purpoſes. The vena portæ, as it is ramified through the Liver, performs the office both of a vein and artery; for, like the former, it returns the blood from the extremities of arteries, while, as the latter, it prepares it for ſecretion.

The nerves of the Liver are branches of the intercoſtal and par vagum. The bile, after being ſeparated from the maſs of blood, is conveyed out of this organ by very minute excretory ducts, called *pori biliarii*; theſe uniting together, like the excretory ducts in the pancreas, gradually form larger ones, which at length terminate in a conſiderable channel, called *ductus hepaticus*.

The Gall-bladder is a little membranous bag, ſhaped like a pear, and attached to the poſterior, and almoſt inferior part of the great lobe of the Liver.

It has two tunics; of which the exterior one is a production of the peritonæum. The interior, or villous coat, is ſupplied with a mucus, that defends it from the acrimony of the bile. Theſe two coverings are intimately connected by means of cellular membrane, which, from its gliſtening appearance, has generally been ſpoken of as a muſcular tunic.

The Gall-bladder is ſupplied with blood-veſſels from the hepatic arteries. Theſe branches are called the *cyſtic arteries*, and the cyſtic veins carry back the blood.

Its nerves are derived from the ſame origin as thoſe of the Liver.

The neck of the Gall-bladder is continued in the form of a canal, called *ductus cyſticus*, which ſoon unites with the ductus hepaticus, which we have deſcribed as the excretory duct of the Liver; and forming one common canal, takes the name of *ductus coledochus communis*, thro' which both the cyſtic and hepatic bile are diſcharged into the duodenum. This canal opens into the inteſtine in an oblique direction, firſt paſſing through the exterior tunic, and then piercing the other coats, after running between each of them a very little way. This œconomy ſerves two uſeful purpoſes; to promote the diſcharge of bile, and to prevent its return.

The bile may be defined to be a natural liquid ſoap, ſomewhat unctuous and bitter, and of a yellowiſh colour, which eaſily mixes with water, oil, and vinous ſpirits, and is capable of diſſolving reſinous ſubſtances.

There are two ſorts of bile; one of which is derived immediately from the Liver, through the hepatic duct, and the other from the Gall-bladder. Theſe two biles, however, do not eſſentially differ from each other. The hepatic bile, indeed, is milder, and more liquid than the cyſtic, which is conſtantly thicker and yellower: and, by being bitterer, ſeems to poſſeſs greater activity than the other.

SECT. X.

OF THE SPLEEN.

THE Spleen is a ſoft and ſpongy viſcus, of a bluiſh colour, and about five or ſix fingers breadth in length, and three in width, ſituated in the left hypochondrium, between the ſtomach and the falſe ribs. That ſide of it which is placed on the ſide of the ribs, is convex; and the other, which is turned towards the ſtomach, is concave.

The Splenic artery, which is a branch from the cæliac, ſupplies this viſcus with blood, and a vein of the ſame name carries it back into the vena portæ.

Its nerves are derived from a particular plexus, called the *ſplenic*, which is formed by branches of the intercoſtal nerve, and by the eighth pair, or par vagum.

The ancients, who ſuppoſed two ſorts of bile, conſidered the Spleen as the receptacle of what they called *atra bilis*. Havers, who wrote profeſſedly on the bones, determined its uſe to be that of ſecreting the ſynovia; and the late Mr. Hewſon imagined, that it concurred with the thymus and lymphatic glands of the body, in forming the red globules of the blood. All theſe opinions ſeem to be equally fanciful. The want of an excretory duct has occaſioned the real uſe of this viſcus to be ſtill doubtful. Perhaps the blood undergoes ſome change in it, which may aſſiſt in the preparation of the bile. This is the opinion of the generality of modern phyſiologiſts; and the great quantity of blood with which it is ſupplied, together with the courſe of its veins into the vena portæ, ſeem to render this notion probable.

SECT. XI.

OF THE GLANDULÆ RENALES, KIDNIES, AND URETERS.

THE Glandulæ Renales, which were by the ancients ſuppoſed to ſecrete the atra bilis, and by them named *capſulæ atrabilares*, are two flat bodies of an irregular figure, one on each ſide, between the kidney and the aorta.

In the fœtus they are as large as the kidnies; but they do not increaſe afterwards in proportion to thoſe parts; and, in adults and old people, they are generally found ſhrivelled, and much waſted. They have their arteries and veins. Their arteries uſually ariſe from the ſplenic or the emulgent, and ſometimes from the aorta; and their veins go to the neighbouring emulgent veins, or to the vena cava. Their nerves are branches of the intercoſtal.

The uſe of theſe parts is not yet perfectly known. In the fœtus the ſecretion of urine muſt be in a very ſmall quantity, and a part of the blood may, perhaps, then paſs through theſe channels, which, in the adult, is carried to the Kidnies, to ſupply the matter of urine.

The Kidnies are two in number, ſituated, one on the right and the other on the left ſide, in the lumbar region, between the laſt falſe rib and the os ilium, by the ſides of the vertebræ. Each Kidney, in its figure, reſembles a ſort of bean, which, from its ſhape, is called *kidney-bean*. The concave part of each Kidney is turned towards the aorta and vena cava aſcendens. They are ſurrounded by a good deal of fat, and receive a coat from the peritonæum; and, when this is removed, a very fine membrane is found inveſting their ſubſtance, and the veſſels which ramify through them.

Each Kidney has a conſiderable artery and vein, which are called the *emulgents*. The artery is a branch from the aorta, and the vein paſſes into the vena cava. Their nerves, which every where accompany the blood-veſſels, ariſe from a conſiderable plexus, which is derived from the intercoſtal.

In each Kidney, which in the adult is of a pretty firm texture, there are three ſubſtances to be diſtinguiſhed. The outer part is glandular or cortical, beyond this is the vaſcular or tubular ſubſtance, and the inner part is papillary or membranous.

It is in the cortical part of the Kidney that the ſecretion is carried on; the urine being here received from the minute extremities of the capillary arteries, is conveyed out of this cortical ſubſtance by an infinite number of very ſmall cylindrical canals or excretory veſſels, which conſtitute the tubular part. Theſe tubes, as they approach the inner ſubſtance of the Kidney, gradually unite together; and thus forming larger canals, at length terminate in ten or twelve little protuberances, called *papillæ*, the orifices of which may be ſeen without the aſſiſtance of glaſſes. Theſe papillæ open into a ſmall cavity or reſervoir called the *pelvis of the kidney*, and formed by a diſtinct membranous bag which embraces the papillæ. From this pelvis the urine is conveyed through a membranous canal which paſſes out from the hollow ſide of the kidney, a little below the blood veſſels, and is called *ureter*.

The ureters are each about as large as a common writing-pen. They are ſomewhat curved in their courſe from the Kidneys, like the letter *ſ*, and at length terminate in the poſterior and almoſt inferior part of the bladder, at ſome diſtance from each other. They paſs into the bladder in the ſame manner as the ductus choledochus communis paſſes into the inteſtinum duodenum, not by a direct paſſage, but by an oblique courſe between the two coats; ſo that the diſcharge of urine into the bladder is promoted, whilſt its return is prevented. Nor does this mode of ſtructure prevent the paſſage of fluids only from the bladder into the ureters, but likewiſe air: for air thrown into the bladder inflates it, and it continues to be diſtended if a ligature is paſſed round its neck; which ſeems to prove ſufficiently that it cannot paſs into the ureters.

SECT. XII.

FEMALE ORGANS OF GENERATION.

ANATOMICAL writers uſually divide the female organs of generation into *external* and *internal*. In the firſt diviſion they include the *mons veneris*, *labia pudendi*, *perinæum*, *clitoris*, *nymphæ*, and *carunculæ myrtiformes*; and in the latter, the *vagina*, with the *uterus* and its appendages.

The *mons veneris*, which is placed on the upper part of the ſymphyſis pubis, is internally compoſed of adipoſe membrane, which makes it ſoft and prominent: it divides into two parts called *labia pudendi*, which deſcending towards the rectum, from which they are divided by the perinæum, from what is called the *fourchette*. The perinæum is that fleſhy ſpace which extends about an inch and an half from the fourchette to the anus, and from thence about two inches to the coccyx.

The labia pudendi being ſeparated, we obſerve a ſulcus called *foſſa magna*; in the upper part of which is placed the clitoris, a ſmall round ſpongy body, in ſome meaſure reſembling the male penis, but impervious, compoſed of two corpora cavernoſa, ariſing from the tuberoſities of the oſſa iſchii; furniſhed with two pair of muſcles, the erectores clitorides, and the ſphincter or conſtrictor oſtii vaginæ; and terminating in a glans, which is covered with its prepuce. From the lower part, on each ſide of the foſſa, paſs the nymphæ, two membranous and ſpongy folds which ſeem deſtined for uſeful purpoſes in parturition, by tending to enlarge the volume of the vagina as the child's head paſſes through it. Between theſe, about the middle of the foſſa magna, we perceive the orifice of the vagina or os externum, cloſed by folds and wrinkles; and about half an inch above this, and about an inch below the clitoris, appears the meatus urinarius or orifice of the urethra, much ſhorter, though ſomewhat larger, than in men, with a little prominence at its lower edge, which facilitates the introduction of the catheter.

The os externum is ſurrounded internally by ſeveral membranous folds called *carunculæ myrtiformes*, which are partly the remains of a thin membrane called *hymen*, that covers the vagina in children. In general the hymen is ſufficiently open to admit the paſſage of the menſes, if it exiſts at the time of their appearance; ſometimes, however, it has been found perfectly cloſed.

The vagina, ſituated between the urethra and the rectum, is a membranous cavity, ſurrounded eſpecially at its external extremity with a ſpongy and vaſcular ſubſtance, which is covered by the ſphincter oſtii vaginæ. It terminates in the uterus, about half an inch above the os tincæ, and is wider and ſhorter in women who have had children than in virgins.

All theſe parts are plentifully ſupplied with blood-veſſels and nerves. Around the nymphæ there are ſebaceous follicles, which pour out a fluid to lubricate the inner ſurface of the vagina; and the meatus urinarius, like the urethra in the male ſubject, is conſtantly moiſtened by a mucus, which defends it againſt the acrimony of the urine.

The *uterus* is a hollow viſcus, ſituated in the hypogaſtric region, between the rectum and bladder.

The uterus, in its unimpregnated ſtate, reſembles a pear in ſhape, ſomewhat flattened, with its fundus or bottom part turned towards the abdomen, and its cervix or neck ſurrounded by the vagina. The entrance into its cavity forms a little protuberance, which has been compared to the mouth of a tench, and is therefore called *os tincæ*.

The ſubſtance of the uterus, which is of a conſiderable thickneſs, appears to be compoſed of muſcular and ſmall ligamentous fibres, ſmall branches of nerves, ſome lymphatics, and with arteries and veins innumerable. Its nerves are chiefly derived from the intercoſtal, and its arteries and veins from the hypogaſtric and ſpermatic. The membrane which lines its cervix, is a continuation of the inner membrane of the vagina; but the outer ſurface of the body of the uterus is covered with the peritonæum, which is reflected over it, and deſcends from thence to the inteſtinum rectum. This duplicature of the peritonæum, by paſſing off from the ſides of the uterus to the ſides of the pelvis, is there firmly connected, and forms what are called *ligamenta uteri lata*; which not only ſerve to ſupport the uterus, but to convey nerves and blood-veſſels to it.

The *ligamenta uteri rotunda* ariſe from the ſides of the fundus uteri, and paſſing along within the fore part of the ligamenta lata, deſcend through the abdominal rings, and terminate in the ſubſtance of the mons veneris. The ſubſtance of theſe ligaments is vaſcular, and although both they and the ligamenta lata admit the uterus in the virgin ſtate, to move only about an inch up and down, yet in the courſe of pregnancy they admit of conſiderable diſtenſion, and after parturition return to their former ſtate with ſurpriſing quickneſs.

On each ſide of the inner ſurface of the uterus, in the angle near the fundus, a ſmall orifice is to be diſcovered, which is the beginning of one of the tubæ fallopaniæ. Each of theſe tubes, which are two in number, paſſing through the ſubſtance of the uterus, is extended along the broad ligaments, till it reaches the edge of the pelvis, from whence it reflects back; and turning over behind the ligaments, about an inch of its extremity is ſeen hanging looſe in the pelvis, near the ovarium. Theſe extremities having a jagged appearance, are called *fimbriæ*, or *morſus diaboli*. Each tuba Fallopiana is uſually about three or four inches long. Their cavities are at firſt very ſmall, but becomes gradually larger, like a trumpet, as they approach the fimbriæ.

Near the fimbriæ of each tuba Fallopiana, about an inch from the uterus, is ſituated an oval body called *ovarium*, of about half the ſize of the male teſticle. Each of theſe ovaria is covered by a production of the peritonæum, and hangs looſe in the pelvis. They are of a flat and angular form, and appear to be compoſed of a white and cellular ſubſtance, in which we are able to diſcover ſeveral minute veſicles filled with a coagulable lymph, of an uncertain number, commonly exceeding 12 in each ovary. In the female of riper years, theſe veſicles become exceedingly turgid, and a kind of yellow coagulum is gradually formed within one of them, which increaſes for a certain time. In conception, one of theſe mature ova is ſuppoſed to be impregnated with the male ſemen, and to be ſqueezed out of its nidus into the Fallopian tube; after which the ruptured part forms a ſubſtance which in ſome animals is of a yellow colour, and is therefore called *corpus luteum*; and it is obſervable, that the number of theſe ſcars or fiſſures in the ovarium, conſtantly correſponds with the number of fœtuſes excluded by the mother.

SECT. XIII.

OF DIGESTION.

BY Digeſtion is to be underſtood, the changes the aliment undergoes for the formation of chyle: the changes are effected in the mouth, ſtomach, and ſmall inteſtines.

The mouth, of which every body has a general knowledge, is the cavity between the two jaws, formed anteriorly and laterially by the lips, teeth, and cheeks, and terminating poſteriorly in the throat.

The lips and cheeks are made up of fat and muſcles, covered by the cuticle, which is continued over the whole inner ſurface of the mouth, like a fine and delicate membrane. Beſide this membrane, the inſide of the mouth is furniſhed with a ſpongy and very vaſcular ſubſtance called the *gums* by means of which the teeth are ſecured in their ſockets. A ſimilar ſubſtance covers the roof of the mouth, and forms what is called the *velum pendulum palati*, which is fixed to the extremity of the arch formed by the oſſa maxillaria and oſſa palati, and terminates in a ſoft, ſmall, and conical body, named *uvula*; which appears, as it were, ſuſpended from the middle of the arch over the baſis of the tongue.

The velum pendulum palati performs the office of a valve between the cavity of the mouth and the pharynx, being moved by ſeveral muſcles.

The tongue is compoſed of ſeveral muſcles which enable it to perform a variety of motions for the articulation of the voice; for the purpoſes of maſtication; and for conveying the aliment into the pharynx. Its upper is covered with papillæ, which conſtitute the organ of taſte, and are eaſily to be diſtinguiſhed; it is covered by the ſame membrane that lines the inſide of the mouth, and which makes at its inferior part towards its baſis a reduplication called *frænum*.

Poſteriorly, under the velum palati, and at the baſis of the tongue, is the pharynx; which is the beginning of the œſophagus, ſtretched out every way, ſo as to reſemble the top of a funnel, through which the aliment paſſes into the ſtomach.

The mouth has a communication with the noſtrils at its poſterior and upper part; with the ears, by the Euſtachian tubes; with the lungs, by means of the larnyx; and with the ſtomach, by means of the œſophagus.

The pharynx is conſtantly moiſtened by a fluid, ſecreted by two conſiderable glands called the *tonſils*, one on each ſide of the velum palati. Theſe glands, from their ſuppoſed reſemblance to almonds, have likewiſe been called *amygdalus*.

The mouth is moiſtened by a conſiderable quantity of ſaliva. This fluid is derived from the *parotid glands*; a name which by its etymology points out their ſituation to be near the ears. They are two in number, one on each ſide under the os malæ: and they are of the conglomerate kind; being formed of many ſmaller glands, each of which ſends out a very ſmall excretory duct, which unites with the reſt, to form one common channel, that runs over the cheek, and piercing the buccinator muſcle, opens into the mouth on each ſide, by an orifice into which a briſtle may be eaſily introduced. Beſides theſe, the maxillary glands, which are placed near the inner ſurface of the angle of the lower jaw on each ſide; the ſublingual glands, which are ſituated at the root of the tongue; the glands of the palate, which are ſeated at the velum palati; and thoſe of the cheeks, lips, &c. together with many other leſs conſiderable ones, pour the ſaliva into the mouth through their ſeveral excretory ducts.

The ſaliva, like all other humours of the body, is found to be different in different people: but in general, it is a limpid and inſipid fluid, without ſmell in healthy ſubjects; and theſe properties would ſeem to prove, that it contains very few ſaline or inflammable particles.

The uſes of the ſaliva ſeem to be to moiſten and lubricate the mouth, and to aſſiſt in reducing the aliment into a ſoft pulp before it is conveyed into the ſtomach.

In the ſtomach, the gaſtric juice, mixes itſelf with the aliment, and helps to prepare it for its paſſage into the inteſtines; but when the ſtomach is perfectly empty, this ſame fluid irritates the coats of the ſtomach itſelf, and produces the ſenſation of hunger.

A certain proportion of liquid aliment is required to aſſiſt in the proceſs of digeſtion, and to afford that moiſture to the body, of which there is ſuch a conſtant diſſipation. Thirſt induces us to take this neceſſary ſupply of drink; and the ſeat of this ſenſation is in the tongue, fauces, and œſophagus, which from their great ſenſibility are required to be kept moiſt: for though the fauces are naturally moiſtened by the mucus and ſalival juices, yet the blood, when deprived of its watery part or rendered acrimonious by any natural cauſes, never fails particularly to affect theſe parts, and the whole alimentary canal, and to occaſion thirſt. This is the common effect of fevers and of hard labour, by both which too much of the watery part of the blood is diſſipated.

The aliment, after having been ſufficiently divided by the action of the teeth, and attenuated by the ſaliva, is received into the ſtomach, where it is deſtined to undergo a more conſiderable change.

The properties of the aliment not being much altered at its firſt entrance into the ſtomach, and before it is thoroughly blended with the gaſtric juice, is capable of irritating the inner coat of the ſtomach to a certain degree, and occaſions a contraction of its two orifices. In this membranous bag, ſurrounded by the abdominal viſcera, and with a certain degree of natural heat, the aliment undergoes a conſtant agitation by means of the abdominal muſcles and of the diaphragm, and likewiſe by a certain contraction or expanſion of the muſcular fibres of the ſtomach itſelf. By this motion, every part of the food is expoſed to the action of the gaſtric juice, which gradually divides and attenuates it, and prepares it for its paſſage into the inteſtines.

But the term of its reſidence in this bag is proportioned to the nature of the aliment, and to the ſtate of the ſtomach and its juices. The thinner and more perfectly digeſted parts of the food paſs by a little at a time into the duodenum, through the pylorus, the fibres of which relax to afford it a paſſage; and the groſſer and leſs digeſted particles remain in the ſtomach, till they acquire a ſufficient fluidity to paſs into the inteſtines, where the nature of the pulp is perfectly changed. The bile and pancreatic juice which flow into the duodenum, and the mucus, which is every where diſtilled from the ſurface of the inteſtines, mix themſelves with the alimentary pulp, which they ſtill farther attenuate and diſſolve, and into which they ſeem to infuſe new properties.

Two matters very different from each other in their nature and deſtination, are the reſult of this combination. One of theſe, which is compoſed of the liquid parts of the aliment, and of ſome of its more ſolid particles, extremely divided and mixed with the juices we have deſcribed, conſtitutes a very mild, ſweet, and whitiſh fluid, reſembling milk, and diſtinguiſhed by the name of chyle. This fluid is abſorbed by the lacteal veſſels, which convey it into the circulation, where, by being aſſimilated into the nature of blood, it affords that ſupply of nutrition, which the continual waſte of the body is found to require. The other, is the remains of the alimentary maſs deprived of all its nutritious particles, and containing only ſuch parts as were rejected by the abſorbing mouths of the lacteals. This groſſer part, called the *fæces*, paſſes on through the courſe of the inteſtines, to be voided at the anus.

SECT. XIV.

OF THE THORAX.

THE Thorax, or cheſt, is that cavity of the trunk which extends from the clavicles, or lower part of the neck, to the diaphragm, and includes the vital organs, which are the heart and lungs; and likewiſe the trachea and œſophagus. This cavity is formed by the ribs and vertebræ of the back, covered by a great number of muſcles, and by the common integuments, and anteriorly by two glandular bodies, called the *breaſts*. The ſpaces between the ribs are filled up by muſcular fibres, which, from their ſituation, are called *intercoſtal muſcles*.

SECT. XV.

OF THE BREASTS.

THE *breaſts* may be defined to be two large conglomerate glands, mixed with a good deal of adipoſe membrane. The glandular part is compoſed of an infinite number of minute arteries, veins, and nerves.

The arteries are derived from two different trunks; one of which is called the *internal*, and the other the *external*, *mammary artery*. The firſt of theſe ariſes from the ſubclavian, and the latter from the axillary.

The veins every where accompany the arteries, and are diſtinguiſhed by the ſame name. The nerves are chiefly from the vertebral pairs. Like all other conglomerate glands, the Breaſts are made up of a great many ſmall diſtinct glands, in which the milk is ſecreted from the ultimate branches of arteries. The excretory ducts of theſe ſeveral glands, gradually uniting as they approach the nipple, form the tubuli lactiferi, which are uſually more than a dozen in number, and open at its apex, but have little or no communication, as has been ſuppoſed, at the root of the nipple.

Theſe ducts, in their courſe from the glands, are ſurrounded by a ligamentary elaſtic ſubſtance, which terminates with them in the nipple. Both this ſubſtance, and the ducts which it contains, are capable of conſiderable extenſion and contraction; but in their natural ſtate are moderately corrugated, ſo as to prevent an involuntary flow of milk, unleſs the diſtending force be very great from the accumulation of too great a quantity.

The whole ſubſtance of the nipple is very ſpongy and elaſtic: its external ſurface is uneven, and full of ſmall tubercles. The nipple is ſurrounded with a diſk or circle of a different colour, called the *areola*; and on the inſide of the ſkin, under the areola, are many ſebaceous glands, which pour out a mucus to defend the areola and nipple: for the ſkin upon theſe parts is very thin; and the nervous papillæ, lying very bare, are much expoſed to irritation.

The Breaſts are formed for the ſecretion of milk, which is deſtined for the nouriſhment of the child for ſome time after its birth. This ſecretion begins to take place ſoon after delivery, and continues to flow for many months in very large quantities, if the woman ſuckles her child.

The operation of ſuction depends on the principles of the air-pump, and the flow of milk through the lactiferous tubes, is facilitated by their being ſtretched out.

The milk, examined chemically, appears to be compoſed of oil, mucilage, and water, and of a conſiderable quantity of ſugar. The generality of phyſiologiſts have ſuppoſed that, like the chyle, it frequently retains the properties of the aliment and medicines taken into the ſtomach; but from ſome late experiments, this ſuppoſition appears to be ill founded.

SECT. XVI.

OF THE PLEURA.

THE cavity of the thorax is every where lined by a membrane of a firm texture, called *pleura*. It is compoſed of two diſtinct portions or bags, which, by being applied to each other laterally, form a ſeptum called *mediaſtinum*; which divides the cavity into two parts, and is attached poſteriorly to the vertebræ of the back, and anteriorly to the ſternum. But the two laminæ of which this ſeptum is formed, do not every where adhere to each other; for, at the lower part of the thorax they are ſeparated, to afford a lodgment to the heart; and, at the upper part of the cavity, they receive between them the thymus.

The Pleura is plentifully ſupplied with arteries and veins from the internal mammary, and the intercoſtals. Its nerves, which are very inconſiderable, are derived chiefly from the dorſal and intercoſtal nerves.

The ſurface of the Pleura, like that of the peritonæum and other membranes lining cavities, is conſtantly bedewed with a ſerous moiſture, which prevents adheſions of the viſcera.

The mediaſtinum, by dividing the Breaſt into two cavities, obviates many inconveniences, to which we ſhould otherwiſe be liable. It prevents the two lobes of the lungs from compreſſing each other when we lie on one ſide; and, conſequently, contributes to the freedom of reſpiration, which is diſturbed by the leaſt preſſure of the lungs. If the point of a ſword penetrates between the ribs, into the cavity of the thorax, the lungs, on that ſide, ceaſe to perform their office; becauſe the air, being admitted through the wound, prevents the dilatation of that lobe; while the other lobe, which is ſeparated from the mediaſtinum, remains unhurt, and continues to perform its functions as uſual.

SECT. XVII.

OF THE THYMUS.

THE *thymus* is a glandular ſubſtance, the uſe of which is not perfectly aſcertained, its excretory duct not having yet been diſcovered. It is of an oblong figure, and is larger in the fœtus, and in young children, than in adults, being ſometimes nearly effaced in very old ſubjects. It is placed in the upper part of the thorax, between the laminæ of the mediaſtinum; but at firſt is not altogether contained within the cavity of the cheſt, being found to border upon the upper extremity of the ſternum.

SECT. XVIII.

OF THE LUNGS.

THE trachea, or windpipe, is a cartilaginous and membranous canal, through which the air paſſes into the lungs. Its upper part, which is called the *larynx*, is compoſed of five cartilages. For a further deſcription ſee MYOLOGY, Part III. Section X.

The glottis is interiorly covered by a very fine membrane, which is moiſtened by a conſtant ſupply of a watery fluid. From the larynx, the canal begins to take the name of *trachea*, or *aſperia arteria*, and extends from thence as far down as the third or fourth vertebra of the back, where it divides into two branches, which are the right and left bronchial tube. Each of theſe bronchi ramifies through the ſubſtance of that lobe of the Lungs, to which it is diſtributed, by an infinite number of branches, which are formed of cartilages ſeparated from each other, like thoſe of the trachea, by an intervening membranous and ligamentary ſubſtance. Each of theſe cartilages is of an angular figure; and as they become gradually leſs and leſs in their diameter, the lower ones are in ſome meaſure received into thoſe above them, when the Lungs, after being inflated, gradually collapſe, by the air being puſhed out from them in exſpiration. As the branches of the bronchi become more minute, their cartilages become more and more angular and membranous, till at length they are found to be perfectly membranous, and at laſt become inviſible.

The trachea is furniſhed with fleſhy or muſcular fibres; ſome of which paſs through its whole extent longitudinally, while the others are carried round it in a circular direction; ſo that by the contraction or relaxation of theſe fibres, it is enabled to ſhorten or lengthen itſelf, and likewiſe to dilate or contract the diameter of its paſſage.

The trachea and branches, in all their ramifications, are furniſhed with a great number of ſmall glands, which are lodged in their cellular ſubſtance, and diſcharge a mucous fluid on the inner ſurface of theſe tubes.

The cartilages of the trachea, by keeping it conſtantly open, afford a free paſſage to the air, which we are obliged to be inceſſantly reſpiring; and its membranous part, by being capable of contraction and dilatation, enables us to receive and expel the air, in a greater or leſs quantity, and with more or leſs velocity, as may be required in ſinging or in declamation. This membranous ſtructure of the trachea poſteriorly, ſeems likewiſe to aſſiſt in the deſcent of the food, by preventing that impediment to its paſſage down the œſophagus, which might be expected if the cartilages were complete rings.

The trachea receives its arteries from the carotid and ſubclavian arteries, and its veins paſs into the jugulars. Its nerves ariſe from the recurrent branch of the eighth pair, and from the cervical plexus.

The Lungs fill the greater part of the cavity of the breaſt. They are of a ſoft and ſpongy texture, and are divided into two lobes, which are ſeparated from each other by the mediaſtinum, and are externally covered by a production of the pleura. Each of theſe is divided into two or three leſſer lobes; and we commonly find three in the right ſide of the cavity, and two in the left.

To diſcover the ſtructure of the Lungs, it is required to follow the ramifications of the bronchi, which were deſcribed in the laſt ſection. Theſe becoming gradually more and more minute, at length terminate in the cellular ſpaces or veſicles, which make up the greateſt part of the ſubſtance of the Lungs, and readily communicate with each other.

The Lungs ſeem to poſſeſs but little ſenſibility. Their nerves, which are ſmall, and few in number, are derived from the intercoſtal and eighth pair. This laſt pair, having reached the thorax, ſends off a branch on each ſide of the trachea, called the *recurrent*, which reaſcends at the back of the trachea, to which it furniſhes branches in its aſcent, as well as to the œſophagus, but it is chiefly diſtributed to the larynx and its muſcles. By dividing the recurrent and ſuperior laryngeal nerves at their origin, an animal is deprived of its voice.

There are two ſeries of arteries which carry blood to the Lungs: theſe are the arteriæ bronchiales, and the pulmonary artery.

The arteriæ bronchiales begin uſually by two branches; one of which commonly ariſes from the right intercoſtal, and the other from the trunk of the aorta: but ſometimes there are three of theſe arteries, and in ſome ſubjects only one. The uſe of theſe arteries is to ſerve for the nouriſhment of the Lungs, and their ramifications are ſeen creeping every where on the branches of the bronchi. The blood is brought back from them by the bronchial vein into the vena azygos.

The pulmonary artery and vein are not intended for the nouriſhment of the Lungs; but the blood, in its paſſage through them, is deſtined to undergo ſome changes, or to acquire certain eſſential properties, from the action of the air, which it has loſt in its circulation through the other parts of the body. The pulmonary artery receives the blood from the right ventricle of the heart, and dividing into two branches, accompanies the bronchi every where, by its ramifications through the Lungs; and the blood is afterwards conveyed back by the pulmonary vein, which gradually forming a conſiderable trunk, goes to empty itſelf into the left ventricle of the heart; ſo that the quantity of blood which enters into the Lungs, is perhaps greater than that which is ſent in the ſame proportion of time, through all the other parts of the body.

SECT. XIX.

OF RESPIRATION.

RESPIRATION conſtitutes one of thoſe functions which are properly termed *vital*, as being eſſential to life; for to live and to breathe are in fact ſynonymous terms. It conſiſts in an alternate contraction and dilatation of the thorax, by firſt inſpiring air into the lungs, and then expelling it from them in exſpiration.

Till within theſe few years phyſiologiſts were entirely ignorant of the uſe of reſpiration. It was at length diſcovered in part by the illuſtrious Dr. Prieſtley. He found that the air exſpired by animals was phlogiſticated; and that the air was fitter for reſpiration, or for ſupporting animal life, in proportion as it was freer from the phlogiſtic principle. It had long been obſerved, that the blood in paſſing through the lungs acquired a more florid colour. He therefore ſuſpected, that it was owing to its having imparted phlogiſton to the air: and he ſatisfied himſelf of the truth of this idea by experiments, which ſhowed, that the craſſamentum of extravaſated blood, phlogiſticated air in proportion as it loſt its dark colour. He farther found, that blood thus reddened had a ſtrong attraction for phlogiſton; inſomuch, that it was capable of taking it from phlogiſticated air, thereby becoming of a darker colour. From hence it appeared that the blood, in its circulation through the arterial ſyſtem, imbibes a conſiderable quantity of phlogiſton, which is diſcharged from it to the air in the lungs.

The blood in this ſtate circulating through the body, imbibes phlogiſton, and of courſe gives out its fire; part only of which is abſorbed by the parts furniſhing the phlogiſton, the remainder, as in combuſtion, becoming ſenſible; and is therefore the cauſe of the heat of the body, or what is called animal heat.

In confirmation of this doctrine it may be obſerved, that the venous blood contains leſs fire than the arterial; combuſtible bodies leſs than incombuſtible ones; and that air contains leſs of this principle, according as it is rendered, by combination with phlogiſton, leſs fit for reſtoration.

SECT. XX.

OF THE PERICARDIUM, AND OF THE HEART.

THE two membranous bags of the pleura, which were deſcribed as forming the mediaſtinum, recede one from the other, ſo as to afford a lodgment to a firm membranous ſac, in which the heart is ſecurely lodged; this ſac, which is the *pericardium*, appears to be compoſed of two tunics, united to each other by cellular membrane. The outer coat is a production of the mediaſtinum; the inner coat, which is extremely thin, is reflected over the auricles and ventricles of the heart, in the ſame manner as the tunica conjunctiva, after lining the eye lids, is reflected over the eye.

This bag adheres to the tendinous part of the diaphragm, and contains a coagulable lymph, the *liquor pericardii*, which ſerves to lubricate the heart and facilitate its motions; and ſeems to be ſecreted and abſorbed in the ſame manner as it is in the other cavities of the body.

The arteries of the pericardium are derived from the phrenic, and its veins paſs into veins of the ſame name; its nerves are likewiſe branches of the phrenic.

The ſize of the pericardium is adapted to that of the heart, being uſually large enough to contain it looſely. As its cavity does not extend to the ſternum, the lungs cover it in inſpiration; and as it every where inveſts the heart, it effectually ſecures it from being injured by lymph, pus, or any other fluid, extravaſated into the cavities of the thorax.

The heart is a hollow muſcle of a conical ſhape, ſituated tranſverſely between the two laminæ of the mediaſtinum, at the lower part of the thorax; having its baſis turned towards the right ſide, and its point or apex towards the left. Its lower ſurface is ſomewhat flattened towards the diaphragm. Its baſis, from which the great veſſels originate, is covered with fat, and it has two hollow and fleſhy appendages, called *auricles*. Round theſe ſeveral openings, the heart ſeems to be of a firm ligamentous texture, from which all its fibres ſeem to originate; and as they advance from thence towards the apex, the ſubſtance of the heart ſeems to become thinner.

The heart includes two cavities or *ventricles*, which are ſeparated from each other by a fleſhy ſeptum; one of theſe is called the *right*, and the other the *left*, *ventricle*; though perhaps, with reſpect to their ſituation, it would be more proper to diſtinguiſh them into the *anterior* and *poſterior ventricles*.

The heart is exteriorly covered by a very fine membrane; and its ſtructure is perfectly muſcular or fleſhy, being compoſed of fibres which are deſcribed as paſſing in different directions; ſome as being extended longitudinally from the baſis to the apex; others, as taking an oblique or ſpiral courſe; and a third ſort as being placed in a tranſverſe direction. Within the two ventricles we obſerve ſeveral furrows; and there are likewiſe tendinous ſtrings, which ariſe from fleſhy columnæ in the two cavities, and are attached to the valves of the auricles. Valvulæ ſemilunares of the arteries are intended to give way to the paſſage of the blood into them from the ventricles, but to oppoſe its return. In conſequence of theſe different uſes, we find the valves of the pulmonary artery and of the aorta attached to the orifices of thoſe veſſels, ſo as to have their concave ſurfaces turned towards the ventricle, only permit the blood to paſs one way, which is into the arteries. There are uſually three of theſe valves belonging to the pulmonary artery, and as many to the aorta; ſo that the other valves which may be ſaid to belong to the veins, are placed in each ventricle, where the auricle opens into it. The valves in the right ventricle are uſually three in number, and are named valvulæ tricuſpides; but in the left ventricle we commonly obſerve only two, and theſe are the valvulæ mitrales. The membranes which form theſe valves in each cavity are attached ſo as to project ſomewhat forward; and both the tricuſpides and the mitrales are connected with the tendinous ſtrings, which were deſcribed as ariſing from the fleſhy columnæ.

By the contraction of either ventricle the blood is driven into the artery which communicates with that ventricle: and theſe tendinous ſtrings being gradually relaxed as the ſides of the cavity are brought nearer to each other, the valves naturally cloſe the opening into the auricle, and the blood neceſſarily directs its courſe into the then only open paſſage, which is into the artery; but after this contraction, the heart becomes relaxed, the tendinous ſtrings are again ſtretched out, and, drawing the valves of the auricle downwards, the blood is poured by the veins into the ventricle, from whence, by another contraction, it is again thrown into the artery. The right ventricle is not quite ſo long, though ſomewhat larger, than the left; but the latter has more ſubſtance than the other: and this ſeems to be, becauſe it is intended to tranſmit the blood to the moſt diſtant parts of the body, whereas the right ventricle diſtributes it only to the lungs.

The heart receives its nerves from the par vagum and the intercoſtals. The arteries which ſerve for its nouriſhment are two in number, and ariſe from the aorta. They ſurround in ſome meaſure the baſis of the heart, and from this courſe are called the coronary arteries. From theſe arteries the blood is returned by veins of the ſame name into the auricles, and even into the ventricles.

The muſcular bags called the auricles are ſituated at the baſis of the heart, at the ſides of each other: and, correſponding with the two ventricles, are like thoſe two cavities diſtinguiſhed into right and left. Theſe ſacs, which are interiorly unequal, have externally a jagged appendix; which, from its having been compared to the extremity of an ear, has given them their name of auricles.

SECT. XXI.

OF THE ACTION OF THE HEART, AURICLES AND ARTERIES.

THE heart, at the time it contracts, drives the blood from its ventricles into the Arteries; and the Arteries being thus filled and diſtended, are naturally inclined to contract the moment the heart begins to dilate, and ceaſes to ſupply them with blood. Theſe alternate motions of contraction and dilatation of the heart and arteries, are diſtinguiſhed by the names of *ſyſtole* and *diaſtole*. When the heart is in a ſtate of contraction or ſyſtole, the arteries are at that inſtant diſtended with blood, and in their diaſtole; and it is in this ſtate we feel their pulſatory motion, which we call the *pulſe*. When the heart dilates, and the Arteries contract, the blood is impelled onwards into the veins, through which it is returned back to the heart. While the heart, however, is in its ſyſtole, the blood cannot paſs from the veins into the ventricles, but is detained in the Auricles.

Although both the ventricles of the heart contract at the ſame time, yet the blood paſſes from one to the other. In the ſame moment, for inſtance, that the left ventricle drives the blood into the aorta, the right ventricle impels it into the pulmonary Artery, which is diſtributed through all the ſubſtance of the lungs. The blood is afterwards brought back into the left ventricle by the pulmonary veins, at the ſame time that the blood is returned by the cavas, into the right ventricle, from all the other parts of the body.

This ſeems to be the mode of action of the heart and its veſſels: but the cauſe of this action has, like all other intricate and intereſting ſubjects, been differently explained. It ſeems to depend on the ſtimulus made on the different parts of the heart by the blood itſelf, which by its quantity and heat, or other properties, is perhaps capable of firſt exciting that motion, which is afterwards continued through life, independent of the will, by a regular return of blood to the Auricles, in a quantity proportioned to that which is thrown into the Arteries.

The heart poſſeſſes the *vis inſita*, or principle of irritability, in a much greater degree than any other muſcle of the body. The pulſe is quicker in young than in old ſubjects, becauſe the former are *cæt. par.* more irritable than the latter. Upon the ſame principle we may explain, why the pulſe is conſtantly quicker in weak than in robuſt perſons.

After what has been obſerved of the ſtructure and action of the heart and its auricles, and likewiſe of the arteries and veins, there ſeem to be but very few arguments required to demonſtrate the circulation of the blood, which has long ſince been eſtabliſhed as a medical truth. This circulation may be defined to be a perpetual motion of the blood, in conſequence of the action of the heart and arteries, which impel it through all the parts of the body, from whence it is brought back by the veins to the heart.

A very ſatisfactory proof of this circulation, and a proof eaſy to be underſtood, may be deduced from the different effects of preſſure on an artery and a vein. If a ligature, for inſtance, is paſſed round an artery, the veſſel ſwells conſiderably between the ligature and the heart; whereas if we tie up a vein, it only becomes filled between the extremity and the ligature, and this is what we every day obſerve in bleeding. The ligature we paſs round the arm on theſe occaſions,

occaſions, compreſſes the ſupercial veins; and the return of the blood through them being impeded, they become diſtended. When the ligature is too looſe, the veins are not ſufficiently compreſſed, and the blood continues its progreſs towards the heart; and, on the contrary, when it is made too tight, the arteries themſelves become compreſſed; and the flow of the blood through them being impeded, the veins cannot be diſtended.

Another phænomenon, which effectually proves the circulation, is the loſs of blood that every living animal ſuſtains by opening only a ſingle artery of a moderate ſize; for it continues to flow from the wounded veſſel till the equilibrium is deſtroyed, which is eſſential to life. This truth was not unknown to the ancients; and it ſeems ſtrange that it did not lead them to a knowledge of the circulation, as it ſufficiently proves, that all the other veſſels muſt communicate with that which is opened. Galen, who lived more than 600 years ago, drew this concluſion from it; and if we farther obſerve, that he deſcribes (after Eraſiſtratus, who flouriſhed about 450 years before him) the ſeveral valves of the heart, and determines their diſpoſition and uſes, it will appear wonderful, that a period of more than 1000 years ſhould afterwards elapſe before the true courſe of the blood was aſcertained. This diſcovery, for which we are indebted to the immortal Harvey, has thrown new lights on phyſiology and the doctrine of diſeaſes, and conſtitutes one of the moſt important periods of anatomical hiſtory.

PART VI.

NEUROLOGY,

AND THE ORGANS OF SENSE.

SECT. I.

OF THE BRAIN AND ITS INTEGUMENTS.

THE Brain is every where ſurrounded by two membranes, the dura and pia mater. The firſt of theſe lines the interior ſurface of the cranium, to which it every where adheres ſtrongly, but more particularly at the ſutures, and at the many foramina through which veſſels paſs betweeen it and the pericranium. The dura mater is perfectly ſmooth and inelaſtic, and its inner ſurface is conſtantly bedewed with a fine pellucid fluid, which every where ſeparates it from the pia mater. The dura mater ſends off ſeveral conſiderable proceſſes, which divide the brain into ſeparate portions and prevent them from compreſſing each other. Of theſe proceſſes there is one ſuperior and longitudinal, called the *falx*, or *falciform proceſs*, from its reſemblance to a ſcythe. It ariſes from the ſpine of the os frontis, near the cryſta galli, and extending along in the direction of the ſagittal ſuture, to beyond the lamboidal ſuture, divides the brain into two hemiſpheres. A little below the lamboidal ſuture, it divides into two broad wings or expanſions called the tranſverſe or lateral proceſſes, which prevents the lobes of the cerebrum from preſſing on the cerebellum. Beſides theſe there is a fourth, which is ſituated under the tranſverſe proceſſes, and being continued to the ſpine of the occiput, divides the cerebellum into two lobes.

The blood, after being diſtributed through the cavity of the cranium by means of the arteries, is returned, as in the other parts of the body, by veins which all paſs on to certain channels, ſituated behind theſe ſeveral proceſſes.

Theſe canals or ſinuſes communicate with each other, and empty themſelves into the internal jugular veins, which convey the blood into the vena cava. They are in fact triangular veins, running through the ſubſtance of the dura mater, and, like the proceſſes, are diſtinguiſhed into longitudinal and lateral; and where theſe three meet, we obſerve they form the torcular Herophili. Herophilus, who firſt deſcribed it, having ſuppoſed that the blood at the union of theſe three veins, is, as it were, in a preſs.

Theſe ſinuſes or veins, by being conveyed through a thick denſe membrane, firmly ſuſpended, as the dura mater is, within the cranium, are leſs liable to rupture; at the ſame time they are well ſupported, and by running every where along the inner ſurface of the bones they are prevented from preſſing on the ſubſtance of the brain. To prevent too great a dilation of them, we find filaments (called chordæ Williſii, from their having been firſt noticed by Willis) ſtretched acroſs their cavities; and the oblique manner in which the veins from the brain run through the ſubſtance of the brain into theſe channels, ſerves the purpoſe of a valve, which prevents the blood from turning back into the ſmaller and weaker veſſels of the brain.

The pia mater is a much ſofter and finer membrane than the dura mater; being exceedingly delicate, tranſparent, and vaſcular. It inveſts every part of the brain, and ſends off an infinite number of elongations, which inſinuate themſelves between the convolutions, and even into the ſubſtance of the brain. This membrane is compoſed of two laminæ; of which the exterior one is named tunica arachnoidea, from its thinneſs, which is equal to that of a ſpider's web. Theſe two laminæ are intimately adherent to each other at the upper part of the brain, but are eaſily ſeparable at the baſis of the brain, and through the whole length of the medulla ſpinalis. The external layer, or tunica arachnoidea, appears to be ſpread uniformly over the ſurface of the brain, but without entering into its furrows as the inner layer does; the latter being found to inſinuate itſelf between the convolutions, and even into the interior cavities of the brain. The blood-veſſels of the brain are diſtributed through it in their way to that organ, and are therefore divided into very minute ramifications, before they penetrate the ſubſtance of the brain.

There are ſeveral parts included under the general denomination of brain. One of theſe, which is of the ſofteſt conſiſtence, and fills the greateſt part of the cavity of the cranium, is the cerebrum, or brain, properly ſo called. Another portion, which is ſeated in the inferior and poſterior part of the head, is the cerebellum; and a third, which derives its origin from both theſe, is the medulla oblongata.

SECT. II.

THE CEREBRUM.

THE Cerebrum is a medullary maſs of a moderate conſiſtence, filling up exactly all the upper part of the cavity of the cranium, and divided into two hemiſpheres by the falx of the dura mater. Each of theſe hemiſpheres is uſually diſtinguiſhed into an interior, a middle and a poſterior lobe. The firſt of theſe is lodged on the orbital proceſſes of the os frontis; the middle lobes lie in the middle foſſæ of the baſis of the cranium, and the poſterior lobes are placed on the tranſverſe ſeptum of the os occipitis, immediately over the cerebellum, from which they are ſeparated by the lateral proceſſes of the dura mater.

The Cerebrum appears to be compoſed of two diſtinct ſubſtances. Of theſe, the exterior one, which is of a greyiſh or aſh-colour, is called the cortex, and is ſomewhat ſofter than the other, which is very white, and is called medulla, or ſubſtantia alba.

After having removed the falx, and ſeparated the two hemiſpheres from each other, we perceive a white convex body, the corpus calloſum, which is a portion of the medullary ſubſtance, uniting the two hemiſpheres to each other, and not inveſted by the cortex. By making an horizontal inciſion in the brain, on a level with this corpus calloſum, we diſcover two oblong cavities, named the anterior or lateral ventricles, one in each hemiſphere. Theſe two ventricles, which communicate with each other by a hole immediately under the plexus choroides, are ſeparated laterally by a very fine medullary partition, called ſeptum lucidum, from its thinneſs and tranſparency. The lower edge of this ſeptum is fixed to the fornix, which is a kind of medullary arch (as its name implies) ſituated under corpus-calloſum, and nearly of a triangular ſhape. Anteriorly the fornix ſends off two medullary chords, called its anterior crura: which ſeem to be united to each other by a portion of medullary ſubſtance, named commiſſura anterior cerebri. Theſe crura diverging from one another, are loſt at the outer ſide of the lower and fore-part of the third ventricle. Poſteriorly the fornix is formed into two other crura, which unite with two medullary protuberances called pedes hippocampi, and ſometimes cornua ammonis, that extend along the back part of the lateral ventricles. The concave edge of the pedes hippocampi is covered by a medullary lamina, called corpus fimbriatum.

Neither the edges of the fornix, nor its poſterior crura, can be well diſtinguiſhed, till we have removed the plexus choroides. This is a production of the pia mater, which is ſpread over the lateral ventricles. Its looſe edges are collected, ſo as to appear like a vaſcular band on each ſide.

When we have removed this plexus, we diſcover ſeveral other protuberances included in the lateral ventricles. Theſe are the corpora ſtriata, the thalami nervorum opticorum, the tubercula quadrugemina, and the pineal gland.

The corpora ſtriata are two curved oblong eminences, that extend along the anterior part of the lateral ventricles. They derive their name from their ſtriated appearance, which is owing to an intermixture of the cortical and medullary ſubſtances of the brain.

The thalami nervorum opticorum, are ſo called, becauſe the optic nerves ariſe chiefly from them, and they are likewiſe compoſed both of the cortex and medulla. They are ſeparated from the corpora ſtriata only by a kind of medullary chord, the geminum centrum ſemi-circulare. The thalami are nearly of an oval ſhape, and are ſituated at the bottom of the upper cavity of the lateral ventricles. They are cloſely united, and at their convex part ſeem to become one body.

Anteriorly, in the ſpace between the thalami, we obſerve an orifice by which the lateral ventricles communicate, and another leads down from this, under the different appellations of foramen commune anterius, vulva, iter ad infundibulum, but more properly iter ad tertium ventriculum; and the ſeparation of the thalami from each other poſteriorly, forms another opening or interſtice called anus. This has been ſuppoſed to communicate with the third ventricle; but it does not, the bottom of it being ſhut up by the pia mater. The back-part of the anus is formed by a kind of medullary band, which connects the thalami to each other, and is called commiſſura poſterior cerebri.

Behind the thalami and commiſſura poſterior, we obſerve a ſmall, ſoft, greyiſh, and oval body, about the ſize of a pea. This is the glandula pinealis; it is deſcribed by Galen under the name of conarion, and has been rendered famous by Deſcartes, who ſuppoſed it to be the ſeat of the ſoul. Galen ſeems formerly to have entertained the ſame opinion. Some modern writers have, with as little reaſon, imagined that the ſoul is placed in the corpus calloſum.

The pineal gland reſts upon four remarkable eminences, diſpoſed in pairs, and ſeated immediately below it. Theſe tubercles, which by the ancients were called teſtes and nates, have, ſince the time of Winſlow, been more commonly named tubercula quadrigemina.

Under the thalami we obſerve another cavity, the third ventricle, which terminates anteriorly in a ſmall medullary canal, the infundibulum, that leads to the glandula pituitaria. It has been doubted, whether the infundibulum is really hollow; but ſome late experiments on this part of the brain, by Profeſſor Murray of Upſal, clearly prove it to be a medullary canal, ſurrounded by both laminæ of the pia mater. After freezing the brain, this channel was found filled with ice.

From the poſterior part of the third ventricle, we ſee a ſmall groove or channel, deſcending obliquely backwards. This channel, which is called the aqueduct of Silvius, though it was known to the antients, opens into another cavity of the brain, placed between the cerebellum and medulla oblongata, and called the fourth ventricle.

SECT. III.

THE CEREBELLUM.

THE Cerebellum, which is divided into two lobes, is commonly ſuppoſed to be of a firmer texture than the cerebrum; but the truth is, that in the greater number of ſubjects, there appears to be no ſenſible difference in the conſiſtence of theſe two parts. It has more of the cortical than of the medullary ſubſtance in its compoſition.

The furrow that divides the two lobes of the cerebellum leads anteriorly to a proceſs, compoſed of medullary and cortical ſubſtances, covered by the pia mater; and which, from its being divided into numerous furrows, reſembling the rings of the earth-worm, is named proceſſus vermiformis. This proceſs forms a kind of ring in its courſe between the lobes.

The ſurface of the cerebellum does not afford thoſe circumvolutions which appear in the cerebrum; but inſtead of theſe, we obſerve a great number of minute furrows, running parallel to each other, and nearly in a tranſverſe direction. The pia mater inſinuates itſelf into theſe furrows.

When we cut into the ſubſtance of the cerebellum, from above downwards, we find the medullary part running in a kind of ramifying courſe, and exhibiting an appearance that has gotten the name of arbor vitæ. Theſe ramifications unite to form a medullary trunk; the middle, anterior, and moſt conſiderable part of which forms two proceſſes, the crura cerebelli, which unite with the crura cerebri, to form the medulla oblongata. The reſt furniſhes two other proceſſes, which loſe themſelves under the nates, and thus unite the lobes of the cerebellum to the poſterior part of the cerebrum. Under the nates we obſerve a tranſverſe medullary line, or linea alba, running from one of theſe proceſſes to the other; and between them we find a very thin medullary lamina, covered with the pia mater, which the generality of anatomiſts have (though ſeemingly without reaſon) conſidered as a valve formed for cloſing the communication between the fourth ventricle and the aquæductus Sylvii. Vieuſſens named it valvula major cerebri.

SECT. IV.

THE MEDULLA OBLONGATA.

THE medulla oblongata is ſituated in the middle, lower, and poſterior part of the cranium, and may be conſidered as a production or continuation of the whole medullary ſubſtance of the cerebrum and cerebellum, being formed by the union of two conſiderable medullary proceſſes of the cerebrum, called crura cerebri, with two other ſmaller ones from the cerebellum, which were juſt now ſpoken of under the name of crura cerebelli.

The crura cerebri ariſe from the middle and lower part of each hemiſphere. They are ſeparated from each other at their origin, but are united below, where they terminate in a middle protuberance, the pons Varolii, ſo called, becauſe Varolius, compared it to a bridge. This name, however, can convey no idea of its real appearance. It is, in fact, nothing more than a medullary protuberance, nearly of a ſemi-ſpherical ſhape, which unites the crura cerebri to thoſe of the cerebellum.

Between the crura cerebri, and near the anterior edge of the pons Varolii, are two tubercles, compoſed externally of medullary, and internally of cineritious, ſubſtance, to which Euſtachius firſt gave the name of eminentiæ mamillares.

Along the middle of the poſterior ſurface of the medulla oblongata, where it forms the anterior part of the fourth ventricle, we obſerve a kind of furrow which runs downwards and terminates in a point. About an inch above the lower extremity of this fiſſure, ſeveral medullary filaments are to be ſeen running towards it on each ſide in an oblique direction, ſo as to give it the appearance of a writing-pen; hence it is called calamus ſcriptorius.

From the poſterior part of the pons Varolii, the medulla oblongata deſcends obliquely backwards; at its fore-part, immediately behind the pons Varolii, we obſerve two pair of eminences, which were deſcribed by Euſtachius, but received no particular appellation till the time of Vieuſſens, who gave them the names of corpora olivaria and corpora pyramidalia. The former are the outermoſt, being placed one on each ſide. They are nearly of an oval ſhape, and are compoſed of medulla, with ſtreaks of cortical ſubſtance. Between theſe are the corpora pyramidalia, each of which terminates in a point. In the human ſubject theſe four eminences are ſometimes not eaſily diſtinguiſhed.

SECT. V.

MEDULLA SPINALIS.

THE medulla ſpinalis, or ſpinal marrow, which is the name given to the medullary chord that is extended down the vertebral canal, from the great foramen of the occipital bone to the bottom of the laſt lumbar vertebra, is a continuation of the medulla oblongata. Like the other parts of the brain, it is inveſted by the dura and pia mater. The firſt of theſe, in its paſſage out of the cranium, adheres to the foramen of the os occipitis. Its connection with the ligamentary ſubſtance that lines the cavity of the ſpine, is only by means of cellular membrane; but between the ſeveral vertebræ, where the nerves paſs out of the ſpine, it ſends off prolongations, which adhere ſtrongly to the vertebral ligaments. Here, as in the cranium, the dura mater has its ſinuſes or large veins. Theſe are two in number, and are ſeen running on each ſide of the medullary column, from the foramen magnum of the os occipitis to the lower part of the os ſacrum. They communicate together by ramifying branches at each vertebra, and terminate in the vertebral, intercoſtal, and ſacral veins.

The pia mater is connected with the dura mater by means of a thin tranſparent ſubſtance, which from its indentations between the ſpinal nerves has obtained the name of ligamentum denticulatum. It is ſomewhat firmer than the tunica arochnoidea, but in other reſpects reſembles that membrane. Its uſe is to ſupport the ſpinal marrow, that it may not affect the medulla oblongata by its weight.

The ſpinal marrow itſelf is externally of a white colour; but upon cutting into it we find its middle-part compoſed of a darker coloured maſs, reſembling the cortex of the brain. When the marrow has reached the firſt lumbar vertebra, it becomes extremely narrow, and at length terminates in an oblong protuberance; from the extremity of which the pia mater ſends off a prolongation or ligament, reſembling a nerve, that perforates the dura mater, and is fixed to the os coccygis.

The medulla ſpinalis gives riſe to 30 or 31 pair of nerves, but they are not all of the ſame ſize, nor do they all run in the ſame direction. The upper ones are thinner than the reſt, and are placed almoſt tranſverſely: as we deſcend we find them running more and more obliquely downwards, till at length their courſe is almoſt perpendicular, ſo that the lowermoſt nerves exhibit an appearance that is called cauda equina, from its reſemblance to a horſe's tail.

The arteries that ramify through the different parts of the brain, are derived from the internal carotid and from the vertebral arteries. The medulla ſpinalis is ſupplied by the anterior and poſterior ſpinal arteries, and likewiſe receives branches from the cervical, the inferior and ſuperior intercoſtal, the lumbar, and the ſacral arteries.

SECT. VI.

ON THE NERVES WHICH GO OFF FROM THE BRAIN, AND SPINAL MARROW.

THE nerves are medullary chords, differing from each other in ſize, colour, and conſiſtence, and deriving their origin from the medulla oblongata and medulla ſpinalis. There are 39, and ſometimes 40, pair of the nerves; nine of which originate from the medulla oblongata, and 30 or 31 from the medulla ſpinalis. They appear to be perfectly inelaſtic, and likewiſe to poſſeſs no irritability. If we irritate muſcular fibres, they immediately contract; but nothing of this ſort happens if we irritate a nerve. They carry with them a covering from the pia mater; but derive no tunic from the dura mater, as hath been generally, though erroneouſly ſuppoſed, ever ſince the time of Galen; the outer covering of the nerves being in fact nothing more than cellular membrane. This covering is very thick where the nerve is expoſed to the action of muſcles; but where it runs through a bony canal, or is ſecure from preſſure, the cellular tunic is extremely thin, or altogether wanting. We have inſtances of this in the portio mollis of the auditory nerve, and in the nerves of the heart.

By elevating, carefully and gently, the brain from the baſis of the cranium, we find the firſt nine pair ariſing in the following order: 1. The nervi olfactorii, diſtributed through the pituitary membrane, which conſtitutes the organ of ſmell. 2. The optici, which go to the eyes, where they receive the impreſſions of viſible objects. 3. The oculorum motores, ſo called becauſe they are diſtributed to the muſcles of the eye. 4. The pathetici, diſtributed to the ſuperior oblique muſcles of the eyes, the motion of which is expreſſive of certain paſſions of the ſoul. 5. The nerves of this pair ſoon divide into three principal branches, and each of theſe has a different name. Its upper diviſion is the opthalamicus, which is diſtributed to various parts of the eyes, eye-lids, fore-head, noſe, and integuments of the face. The ſecond is called maxillaris ſuperior, and the third maxillaris inferior; both which names allude to their diſtribution. 6. The abductores; each of theſe nerves is diſtributed to the abductor muſcle of the eye, ſo called, becauſe it helps to draw the globe of the eye from the noſe. 7, The auditorii, which are diſtributed through the organs of hearing. 8, The par vagum, which derives its name from the great number of parts, to which it gives branches both in the thorax and abdomen. 9. The linguales, or hypogloſſi, which are diſtributed to the tongue, and appear to contribute both to the organ of taſte and to the motions of the tongue.

It has already been obſerved, that the ſpinal marrow ſends off 30 or 31 pair of nerves; theſe are chiefly diſtributed to the exterior parts of the trunk and to the extremities. They are commonly diſtinguiſhed into the cervical, dorſal, lumbar, and ſacral nerves. The cervical, which paſs out from between the ſeveral vertebræ of the neck, are eight in number; the dorſal, twelve; the lumbar, five; and the ſacral, five or ſix; the number of the latter depending on the number of holes in the os ſacrum. Each ſpinal nerve at its origin is compoſed of two faſciculi of medullary fibres. One of theſe faſciculi ariſes from the anterior, and the other from the poſterior, ſurface of the medulla. Theſe faſciculi are ſeparated by the ligamentum denticulatum; after which we find them contiguous to one another. They then perforate the dura mater, and unite to form a conſiderable knot or ganglion. Each of theſe ganglions ſends off two branches; one anterior, and the other poſterior. The anterior branches communicate with each other at their coming out of the ſpine, and likewiſe ſend off one, and ſometimes more branches, to aſſiſt in the formation of the intercoſtal nerve.

Explanation of the PLATES *on the* BRAIN.

FIGURE I.

The Baſis of the Brain, ſeen from before.

A, A, Its anterior lobes. B, B, Its middle lobes. C, C, Poſterior lobes. D, D, Cerebellum. E, E, Corpora pyramidalia. F, F, Corpora olivaria. G, G, Pons varolii. H, H, Medulla oblongata, with the origin of the nerves. I, Medulla ſpinales at its beginning. K, Olfactory nerves. L, L, Second pair, or the optic. M, M, Third pair, or the pathetic. N, N, Fourth pair. O, O, Fifth pair. P, P, Sixth pair. Q, Q, Seventh pair, or auditory, its porteo dura, and mollis. R, R, Eighth pair, or par vagum. S, S, Ninth pair, or lingual. T, T, Vertebral arteries. U, Baſilary artery. V, V, Internal carotids. W, W, Circulus arterioſus Williſii.

FIGURE II.

Exhibits an Horizonal Section of the Brain, the upper Part of the Two Hemiſpheres being removed to ſhew the two Lateral Ventricles and their Contents.

A, A, Medulla of the brain. B, B, Its cortical ſubſtance. C, Part of the cerebellum. D, Corpus calloſum. E, E, Corpora ſtriata. F, F, Thalami nervorum opticorum. G, Fornix. H, H, Plexus choroides. I, Pineal gland. K, K, Anterior cornua of the ventricles. L, L, Poſterior ditto.

FIGURE III.

Exhibits the Baſis of the Cranium, lined by the Dura Mater, where is ſeen the Beginning of many Nerves, Blood Veſſels, &c.

A, A, Tentorium cerebelli. B, Longitudinal ſinus of dura mater. C, Falciform proceſs. D, D, Lateral ſinuſſes. E, E, Arteries of the dura mater. F, F, Carotid arteries. G G, Opthalmic arteries. H, Criſta galli. I, I, Frontal ſinus. K, K, Fifth pair of nerves. L, L, Fourth pair. M, M, Third pair. N, N, Origin of the intercoſtal nerve. O, O, Seventh pair of nerves. P, P, Eighth pair. Q, Q, Ninth pair. R, Glandula lachrymalis. S, S, Optic nerve. T, T, Sixth pair of nerves. U, Foramen magnum occipitale.

ON THE MORE DISTANT DISTRIBUTION OF THE NERVES.

And Explanation of the PLATE *on that Subject.*

FIGURE I.

Repreſents the inferior Part of the Brain; the anterior Part of the whole Spine, including the Medulla Spinalis; with the Origin and large Portions of all the Nerves.

A, A, The anterior lobes of the cerebrum. B, B, The lateral lobes of the cerebrum. C, C, The two lobes of the cerebellum. D, Tuber annulare. E, The paſſage from the third ventricle to the infundibulum. F, The medulla oblongata, which ſends off the medulla ſpinalis through the ſpine. G, G, That part of the os occipitis which is placed above (H,H) the tranſverſe proceſſes of the firſt cervical vertebra. I, I, &c. The ſeven cervical vertebræ, with their intermediate cartilages. K, K, &c. The twelve dorſal vertebræ, with their intermediate cartilages. L, L, &c. The five lumbar vertebræ, with their intermediate cartilages. M, The os ſacrum. N, The os coccygis.

NERVES. 1 1, The firſt pair of nerves, named olfactory, which go to the noſe. 2 2, The ſecond pair, named optic, which go to form the tunica retina of the eye. 3 3, The third pair, named motor oculi, ſupply moſt of the muſcles of the eye-ball. 4 4, The fourth pair, named pathetic, which are wholly ſpent upon the muſculus trochlearis of the eye. 5 5, The fifth pair divides into three branches. The firſt, named opthalmic, goes to the orbit, ſupplies the lachrymal gland, and ſends branches out to the forehead and noſe. The ſecond, named ſuperior maxillary, ſupplies the teeth of the upper jaw, and ſome of the muſcles of the lips. The third, named inferior maxillary, is ſpent upon the muſcles and teeth of the lower jaw, tongue, and muſcles of the lips. 6 6, The ſixth pair, which, after ſending off the beginning of the intercoſtal or great ſympathetic, is ſpent upon the abductor oculi. 7 7, The ſeventh pair, named auditory, divides into two branches. The largeſt, named portio mollis, is ſpent upon the internal ear. The ſmalleſt, portio dura, joins to the fifth pair within the internal ear, by a reflected branch from the ſecond of the fifth; and within the tympanum, by a branch from the third of the fifth, named chorda tympani.

The eighth pair, named par vagum, which accompanies the intercoſtal, and is ſpent upon the tongue, larynx, pharynx, lungs, and abdominal viſcera. 9 9, The ninth pair, which are ſpent upon the tongue. 10 10, &c. The intercoſtal, or great ſympathetic, which is ſeen from the ſixth pair to the bottom of the pelvis on each ſide of the ſpine, and joining with all the nerves of the ſpine; in its progreſs ſupplying the heart, and, with the par vagum, the contents of the abdomen and pelvis. 11 11, The acceſſorius, which is ſpent upon the ſternocleido-maſtoidæus and trapezius muſcles. 12 12, The firſt cervical nerves. 13 13, The ſecond cervical nerves; both ſpent upon the muſcles that lie on the neck, and teguments of the neck and head. 14 14, The third cervical nerves, which, after ſending off (15 15, &c.) the phrenic nerves to the diaphragm, ſupply the muſcles and teguments that lie on the ſide of the neck and top of the ſhoulder. 16 16, The brachial plexus, formed by the fourth, fifth, ſixth, ſeventh cervicals, and firſt dorſal nerves, which ſupply the muſcles and teguments of the ſuperior extremity. 17 17, The twelve dorſal, or proper intercoſtal nerves, which are ſpent upon the intercoſtal muſcles and ſome of the large muſcles which lie upon the thorax. 18 18, The five lumbar pairs of nerves, which ſupply the lumbar and abdominal muſcles, and ſome of the teguments and muſcles of the inferior extremity, making the anterior crural, and obturator nerves. 19 19, The ſacro-ſciatic, or poſterior crural nerve, formed by the two inferior lumbar, and three ſuperior of the os ſacrum. This large nerve ſupplies the greateſt part of the muſcles and teguments of the inferior extremity. 20 20, The ſtomachic plexus, formed by the eighth pair. 21 21, Branches of the ſolar, or cæliac plexus, formed by the eighth pair and intercoſtals, which ſupply the ſtomach and chylopoietic viſcera. 22 22, Branches of the ſuperior and inferior meſenteric plexuſes, formed by the eighth pair and intercoſtals, which ſupply the chylopoietic viſcera, with part of the organs of urine and generation. 23 23, Nerves which accompany the ſpermatic cord. 24 24, The hypogaſtric plexus, which ſupplies the organs of urine and generation within the pelvis.

OF THE SENSES.

THE External Senſes are five in number, viz. Touch, Taſte, Smelling, Hearing, and Viſion.

SECT. VII.

OF TOUCH.

THE ſenſe of touch may be defined to be the faculty of diſtinguiſhing certain properties of bodies by the feel. In a general acceptation, this definition might perhaps not improperly be extended to every part of the body poſſeſſed of ſenſibility; but it is commonly confined to the nervous papillæ of the cutis, or true ſkin.

The cutis is compoſed of fibres cloſely compacted together, as we may obſerve in leather, which is the prepared ſkin of animals. Theſe fibres form a thick net-work, which every where admits the filaments of nerves, and an infinite number of blood-veſſels and lymphatics.

The cutis, when the epidermis is taken off, is found to have, throughout its whole ſurface, innumerable papillæ, which appear like very minute granulations, and ſeem to be calculated to receive the impreſſions of the touch, being the moſt eaſily obſerved where the ſenſe of feeling is the moſt delicate, as in the palms of the hands, and on the fingers.

Theſe papillæ are ſuppoſed, by many anatomical writers, to be continuations of the pulpy ſubſtance of nerves, whoſe coats have terminated in the cellular texture of the ſkin. The great ſenſibility of theſe papillæ evidently proves them to be exceedingly nervous. Theſe papillæ being deſcribed, the uſes of the epidermis, and the reticulum mucoſum which covers them, will be more eaſily underſtood; the latter ſerving to keep them conſtantly moiſt, while the former protects them from the external air, and modifies their too great ſenſibility.

The exterior properties of bodies, ſuch as their ſolidity, moiſture, inequality, ſmoothneſs, dryneſs, or fluidity, and likewiſe their degree of heat, ſeem all to be capable of making different impreſſions on the papillæ, and conſequently of exciting different ideas in the ſenſorium commune. But the organ of touch, like all the other ſenſes, is not equally delicate in every part of the body, or in every ſubject; being in ſome much more exquiſite than in others.

SECT. VIII.

OF THE TASTE.

THE ſenſe of taſte is ſeated chiefly in the tongue.

On the upper ſurface of this organ we may obſerve a great number of papillæ, which, on account of their difference in ſize and ſhape, are commonly divided into three claſſes. The largeſt are ſituated towards the baſis of the tongue. Their number commonly varies from ſeven to nine, and they ſeem to be mucous follicles. Thoſe of the ſecond claſs are ſomewhat ſmaller, and of a cylindrical ſhape. They are moſt numerous about the middle of the tongue. Thoſe of the third claſs are very minute, and of a conical ſhape. They are very numerous on the apex and edges of the tongue, and have been ſuppoſed to be formed by the extremities of its nerves.

We obſerve a line, the linea linguæ mediana, running along the middle of the tongue, and dividing it as it were into two portions. Towards the baſis of the tongue, we meet with a little cavity, named by Morgagni foramen cæcum, which ſeems to be nothing more than a common termination of ſome of the excretory ducts of mucous glands ſituated within the ſubſtance of the tongue.

We have already obſerved, that this organ is every where covered by the cuticle, which, by forming a reduplication, called the frænum, at its under part, ſerves to prevent the too great motion of the tongue, and to fix it in its ſituation. But, beſides this attachment, the tongue is connected by means of its muſcles and membranous ligaments, to the lower jaw, the os hyoides, and the ſtyloid proceſſes.

The principal arteries of the tongue are the linguales, which ariſe from the external carotid. Its veins empty themſelves into the external jugulars. Its nerves ariſe from the fifth, eighth, and ninth pair.

The variety of taſtes ſeems to be occaſioned by the different impreſſions made on the papillæ by the food. The different ſtate of the papillæ with reſpect to their moiſture, their figure, or their covering, ſeems to produce a conſiderable difference in the taſte, not only in different people, but in the ſame ſubject, in ſickneſs and in health. The great uſe of the taſte ſeems to be to enable us to diſtinguiſh wholeſome and ſalutary food from that which is unhealthy; and we obſerve, that many quadrupeds, by having their papillæ very large and long, have the faculty of diſtinguiſhing flavours with infinite accuracy.

SECT. IX.

OF SMELLING.

THE ſenſe of ſmelling, like the ſenſe of taſte, ſeems intended to direct us to a proper choice of aliment, and is chiefly ſeated in the noſe, which is diſtinguiſhed into its external and internal parts. The ſituation and figure of the former of theſe do not ſeem to require a definition. It is compoſed of bones and cartilages, covered by muſcular fibres, and by the common integuments. The bones make up the upper portion, and the cartilages the lower one. The ſeptum narium, like the noſe, is likewiſe in part bony, and in part cartilaginous. Theſe bones and their connection were deſcribed in the Oſteology.

The internal part of the noſe, beſides the oſſa ſpongioſa, has ſix cavities or ſinuſes, the maxillary, the frontal, and the ſphenoid on each ſide, which were all deſcribed with the bones of the head. They all open into the noſtrils; and the noſe likewiſe communicates with the mouth, larynx, and pharynx, poſteriorly behind the velum palati.

All theſe ſeveral parts, which are included in the internal diviſion of the noſe, viz. the inner ſurface of the noſtrils, the lamellæ of the oſſa ſpongioſa, and the ſinuſes, are lined by a thick and very vaſcular membrane, which, though not unknown to the ancients, was firſt well deſcribed by Schneider, and is therefore now commonly named membrana pituitaria Schneideri. This membrane is truly the organ of ſmelling; but its real ſtructure does not yet ſeem to be perfectly underſtood. It appears to be a continuation of the cuticle, which lines the inner ſurface of the mouth. In ſome parts of the noſe it is ſmooth and firm, and in others it is looſe and ſpongy. It is conſtantly moiſtened by a mucous ſecretion; the finer parts of which are carried off by the air we breathe, and the remainder, by being retained in the ſinuſes, acquires conſiderable conſiſtence. The manner in which this mucus is ſecreted has not yet been ſatisfactorily aſcertained; but it ſeems to be by means of mucous follicles.

Its arteries are branches of the internal maxillary and internal carotid. Its veins empty themſelves into the internal jugulars. The firſt pair of nerves, the olfactory, are ſpread over every part of it, and it likewiſe receives branches from the fifth pair.

After what has been ſaid of the pituitary membrane, it will not be difficult to conceive how the air we draw in at the noſtrils, being impregnated with the effluvia of bodies, excites in us that kind of ſenſation we call ſmelling. As theſe effluvia, from their being exceedingly light and volatile, cannot be capable in a ſmall quantity of making any great impreſſion on the extremities of the olfactory nerves, it was neceſſary to give conſiderable extent to the pituitary membrane, that by this means a greater number of odoriferous particles might be admitted at the ſame time. When we wiſh to take in much of the effluvia of any thing, we naturally cloſe the mouth, that all the air we inſpire may paſs through the noſtrils; and at the ſame time, by means of the muſcles of the noſe, the noſtrils are dilated, and a greater quantity of air is drawn into them.

In many quadrupeds, the ſenſe of ſmelling is much more extenſive and delicate than it is in the human ſubject; and in the human ſubject it ſeems to be more perfect the leſs it is vitiated by a variety of ſmells. It is not always in the ſame ſtate of perfection, being naturally affected by every change of the pituitary membrane, and of the lymph with which that membrane is moiſtened.

SECT. X.

OF HEARING.

BEFORE we undertake to explain the manner in which we are enabled to receive the impreſſions of ſound, it will be neceſſary to deſcribe the ear, which is the organ of Hearing. It is commonly diſtinguiſhed into external and internal. The former of theſe diviſions includes all that we are able to diſcover without diſſection, and the meatus auditorius, as far as the tympanum; and the latter, all the other parts of the ear.

The external ear is a cartilaginous funnel, covered by the common integuments, and attached, by means of its ligaments and muſcles, to the temporal bone. Although capable only of a very obſcure motion, it is found to have ſeveral muſcles. Different parts of it are diſtinguiſhed by different names; all its cartilaginous part is called ala or wing, to diſtinguiſh it from the ſoft and pendent part below, called the lobe. Its outer circle or border is called helix, and the ſemicircle within this, antihelix. The moveable cartilage placed immediately before the meatus auditorius, which it may be made to cloſe exactly, is named tragus; and an eminence oppoſite to this at the extremity of the antihelix, is called antitragus. The concha is a conſiderable cavity formed by extremities of the helix and antihelix. The meatus auditorius, which at its opening is cartilaginous, is lined with a very thin membrane, which is a continuation of the cuticle from the ſurface of the ear.

In this canal we find a yellow wax, which is ſecreted by a number of minute glands or follicles, each of which has an excretory duct. This ſecretion, which is at firſt of an oily conſiſtence, defends the membrane of the tympanum from the injuries of the air; and by its bitterneſs, prevents minute inſects from entering into the ear. But when from neglect or diſeaſe it accumulates in too great a quantity, it ſometimes occaſions deafneſs. The inner extremity of the meatus is cloſed by a very thin tranſparent membrane, the membrana tympani, which is ſet in a bony circle like the head of a drum. In the laſt century Rivinus, profeſſor at Leipſic, fancied he had diſcovered a hole in this membrane, ſurrounded by a ſphincter, and affording a paſſage to the air, between the external and internal ear. Cowper, Heiſter, and ſome other anatomiſts, have admitted this ſuppoſed foramen, which certainly does not exiſt. Whenever there is any opening in the membrana tympani, it may be conſidered as accidental. Under the membrana tympani runs a branch of the fifth pair of nerves, called chorda tympani; and beyond this membrane is the cavity of the tympanum, which is about ſeven or eight lines wide, and half ſo many in depth; it is ſemiſpherical, and every where lined by a very fine membrane. There are four openings to be obſerved in this cavity. It communicates with the mouth by means of the Euſtachian tube. This canal, which is in part bony and in part cartilaginous, begins by a very narrow opening at the anterior and almoſt ſuperior part of the tympanum, increaſing in ſize as it advances towards the palate of the mouth, where it terminates by an oval opening. This tube is every where lined by the ſame membrane that covers the inſide of the mouth. Oppoſite to this is a paſſage, which leads to the ſinuoſities of the maſtoid proceſs; and the two other openings, which are in the internal proceſs of the os petroſum, are the feneſtra ovalis, and feneſtra rotunda, both of which are covered by a very fine membrane.

There are three diſtinct bones in the cavity of the tympanum; and theſe are the malleus, incus, and ſtapes. Beſides theſe there is a fourth, which is the os orbiculare, conſidered by ſome anatomiſts as a proceſs of the ſtapes, which is neceſſarily broken off by the violence we are obliged to uſe in getting at theſe bones; but when accurately conſidered, it ſeems to be a diſtinct bone.

The malleus is ſuppoſed to reſemble a hammer, being larger at one extremity, which is its head, than it is at the other, which is its handle. The latter is attached to the membrana tympani, and the head of the bone is articulated with the incus.

The incus, as it is called from its ſhape, though it ſeems to have leſs reſemblance to an anvil than to one of the dentes molares with its roots widely ſeparated from each other, is diſtinguiſhed into its body and its legs. One of its legs is placed at the entry of the canal which leads to the maſtoid proceſs; and the other, which is ſomewhat longer, is articulated with the ſtapes, or rather with the os orbiculare, which is placed between them.

The third bone is very properly named ſtapes, being perfectly ſhaped like a ſtirrup. Its baſis is fixed into the feneſtra ovalis, and its upper part is articulated with the os orbiculare. What is called the feneſtra rotunda, though perhaps improperly, as it is more oval than round, is obſerved a little above the other, in an eminence formed by the os petroſum, and is cloſed by a continuation of the membrane that lines the inner ſurface of the tympanum. The ſtapes and malleus are each of them furniſhed with a little muſcle, the ſtapedeus and tenſor tympani. The firſt of theſe, which is the ſmalleſt in the body, ariſes from a little cavern in the poſterior and upper part of the cavity of the tympanum; and its tendon, after paſſing through a hole in the ſame cavern, is inſerted at the back part of the head of the ſtapes. This muſcle, by drawing the ſtapes obliquely upwards, aſſiſts in ſtretching the membrana tympani. The tenſor tympani, or internus mallei, as it is called by ſome writers, ariſes from the cartilaginous extremity of the Euſtachian tube, and is inſerted into the back part of the handle of the malleus, which it ſerves to pull inwards, and of courſe helps to ſtretch the membrana tympani.

The labyrinth is the only part of the ear which remains to be deſcribed. It is ſituated in the os petroſum, and is ſeparated from the tympanum by a partition which is every where bony, except at the two feneſtræ. It is compoſed of three parts; and theſe are the veſtibulum, the ſemicircular canals, and the cochlea.

The veſtibulum is an irregular cavity, much ſmaller than the tympanum, ſituated nearly in the centre of the os petroſum, between the tympanum, the cochlea, and the ſemicircular canals. It is open on the ſide of the tympanum by means of the feneſtra ovalis, and communicates with the upper portion of the cochlea by an oblong foramen, which is under the feneſtra ovalis, from which it is ſeparated only by a very thin partition.

Each of the three ſemicircular canals forms above half a circle of nearly a line in diameter, and running each in a different direction, they are diſtinguiſhed into vertical, oblique, and horizontal. Theſe three canals open by both their extremities into the veſtibulum; but the vertical and the oblique being united together at one of their extremities, there are only five orifices to be ſeen in the veſtibulum.

The cochlea is a canal which takes a ſpiral courſe, not unlike the ſhell of a ſnail. From its baſis to its apex it makes two turns and a half; and is divided into two canals by a very thin lamina or ſeptum, which is in part bony and in part membranous, in ſuch a manner that theſe two canals only communicate with each other at the point. One of them opens into the veſtibulum, and the other is covered by the membrane that cloſes the feneſtra rotunda. The bony lamella which ſeparates the two canals is exceedingly thin, and fills about two thirds of the diameter of the canal. The reſt of the ſeptum is compoſed of a moſt delicate membrane, which lines the whole inner ſurface of the cochlea, and ſeems to form this diviſion in the ſame manner as the two membranous bags of the pleura, by being applied to each other, form the mediaſtinum.

Every part of the labyrinth is furniſhed with a very delicate perioſteum, and filled with a watery fluid, ſecreted as in other cavities. This fluid tranſmits to the nerves the vibrations it receives from the membrane cloſing the feneſtra rotunda, and from the baſis of the ſtapes, where it reſts on the feneſtrum ovale.

The arteries of the external ear come from the temporal and other branches of the external carotid, and its veins paſs into the jugular. The internal ear receives branches of arteries from the baſilary and carotids, and its veins empty themſelves into the ſinuſes of the dura mater, and into the internal jugular.

The portio mollis of the ſeventh pair is diſtributed through the cochlea, the veſtibulum, and the ſemi-circular canals; and and the portio dura ſends off a branch to the tympanum, and other branches to the external ear and parts near it.

The ſenſe of hearing, in producing which all the parts we have deſcribed aſſiſt, is occaſioned by a certain modulation of the air collected by the funnel-like ſhape of the external ear, and conveyed through the meatus auditorius to the membrana tympani. That ſound is propagated by means of the air, is very eaſily proved by ringing a bell under the receiver of an air-pump;

the ſound it affords being found to diminiſh gradually as the air becomes exhauſted, till at length it ceaſes to be heard at all. Sound moves through the air with infinite velocity; but the degree of its motion ſeems to depend on the ſtate of the air, as it conſtantly moves faſter in a denſe and dry, than it does in a moiſt and rarefied air. See Acoustics.

That the air vibrating on the membrana tympana communicates its vibration to the different parts of the labyrinth, and by means of the fluid contained in this cavity effects the auditory nerve ſo as to produce ſound, ſeems to be very probable; but the ſituation, the minuteneſs, and the variety of the parts which compoſe the ear, do not permit much to be advanced with certainty concerning their mode of action.

Some of theſe parts ſeem to conſtitute the immediate organ of hearing, and theſe are all the parts of the veſtibulum: but there are others which ſeem intended for the perfection of this ſenſe, without being abſolutely eſſential to it. It has happened, for inſtance, that the membrana tympani, and the little bones of the ear, have been deſtroyed by diſeaſe, without depriving the patient of the ſenſe of hearing.

Sound is more or leſs loud in proportion to the ſtrength of the vibration; and the variety of ſounds ſeems to depend on the difference of this vibration; for the more quick and frequent it is, the more acute will be the ſound, and vice verſa.

Before we conclude this article, it will be right to explain certain phenomena, which will be found to have a relation to the organ of hearing.

Every body has, in conſequence of particular ſounds, occaſionally felt that diſagreeable ſenſation which is uſually called ſetting the teeth on edge: and the cauſe of this ſenſation may be traced to the communication which the portio dura of the auditory nerve has with the branches of the fifth pair that are diſtributed to the teeth, being properly occaſioned by the violent tremour produced in the membrana tympani by theſe very acute ſounds. Upon the ſame principle we may explain the ſtrong idea of ſound which a perſon who has holds a vibrating ſtring between his teeth.

SECT. XI.

OF VISION.

THE eyes, which conſtitute the organ of viſion, are ſituated in two bony cavities named orbits, where they are ſurrounded by ſeveral parts, which are either intended to protect them from external injury, or to aſſiſt in their motion.

The globe of the eye is immediately covered by two eye-lids or palpebræ, which are compoſed of muſcular fibres covered by the common integuments, and lined by a very fine and ſmooth membrane, which is from thence extended over part of the globe of the eye, and is called tunica conjunctiva. Each eye-lid is cartilaginous at its edge; and this border, which is called tarſus, is furniſhed with a row of hairs named cilia or eye-laſhes.

The cilia ſerve to protect the eye from inſects and minute bodies floating in the air, and likewiſe to moderate the action of the rays of light in their paſſage to the retina. At the roots of theſe hairs there are ſebaceous follicles, firſt noticed by Meibomius, which diſcharge a glutinous liniment. Sometimes the fluid they ſecrete has too much viſcidity, and the eye-lids become glued to each other.

The upper border of the orbit is covered by the eye-brows or ſupercilia, which by means of their two muſcles are capable of being brought towards each other, or of being carried upwards. They have been conſidered as ſerving to protect the eyes, but they are probably intended more for ornament than utility.

The orbits, in which the eyes are placed, are furniſhed with a good deal of fat, which affords a ſoft bed on which the eye performs its ſeveral motions. The inner angle of each orbit, or that part of it which is near the noſe, is called canthus major, or the great angle; and the outer angle, which is on the oppoſite ſide of the eye, is the canthus minor, or little angle.

The little reddiſh body which we obſerve in the great angle of the eye-lids, and which is called caruncula lachrymalis, is ſuppoſed to be of a glandular ſtructure, and, like the follicles of the eye-lids, to ſecrete an oily humour. But its ſtructure and uſe do not ſeem to have been hitherto accurately determined. The ſurface of the eye is conſtantly moiſtened by a very fine limpid fluid called the tears, which is chiefly, and perhaps wholly, derived from a large gland of the conglomerate kind, ſituated in a ſmall depreſſion of the os frontis near the outer angle of the eye. Its excretory ducts pierce the tunica conjunctiva juſt above the cartilaginous borders of the upper eye-lids. When the tears were ſuppoſed to be ſecreted by the caruncule, this gland was called glanula innominata; but now that its ſtructure and uſes are aſcertained, it very properly has the name of glandula lachrymalis. The tears poured out by the ducts of this gland are, in a natural and healthy ſtate, inceſſantly ſpread over the ſurface of the eye, to keep it clear and tranſparent, by means of the eye-lids, and as conſtantly paſs out at the oppoſite corner of the eye or inner angle, through two minute orifices, the puncta lachrymalia; being determined into theſe little openings by a republication of the tunica conjunctiva, ſhaped like a creſent, the two points of which anſwer to the puncta. This republication is named membrana, or valvula ſemilunaris. Each of theſe puncta is the begining of a ſmall excretory tube, through which the tears paſs into a little pouch or reſervoir, the ſacculus lachrymalis, which lies in an excavation formed partly by the naſal proceſs of the os maxillare ſuperius, and partly by the os unguis. The lower part of this ſac forms a duct called the ductus ad naſum, which is continued through a bony channel, and opens into the noſe, through which the tears are occaſionally diſcharged.

The motions of the eye are performed by ſix muſcles; four of which are ſtraight and two oblique. The ſtraight muſcles are diſtinguiſhed by the names of elevator, depreſſor, adductor, and abductor, from their ſeveral uſes in elevating and depreſſing the eye, drawing it towards the noſe, or carrying it from the noſe towards the temple. All theſe four muſcles ariſe from the bottom of the orbit, and are inſerted by flat tendons into the globe of the eye. The oblique muſcles are intended for the more compound motions of the eye. The firſt of theſe muſcles, the obliquus ſuperior, does not, like the other four muſcles we have deſcribed, ariſe from the bottom of the orbit, but from the edge of the foramen that tranſmits the optic nerve, which ſeparates the origin of this muſcle from that of the others. From this beginning it paſſes in a ſtraight line towards a very ſmall cartilaginous ring, the ſituation of which is marked in the ſkeleton by a little hollow in the internal orbitar proceſs of the os frontis. The tendon of the muſcle, after paſſing through this ring, is inſerted into the upper part of the globe of the eye, which it ſerves to draw forwards, at the ſame time turning the pupil downwards.

The obliquus inferior ariſes from the edge of the orbit, under the opening of the ductus lachrymalis; and is inſerted ſomewhat poſteriorly into the outer ſide of the globe, ſerving to draw the eye forwards and turn the pupil upwards. When either of theſe two muſcles acts ſeparately, the eye is moved on its axis; but when they act together, it is compreſſed both above and below. The eye itſelf, which is now to be deſcribed, with its tunics, humours, and component parts, is nearly of a ſpherical figure. Of its tunics, the conjunctiva has been already deſcribed as a partial covering, reflected from the inner ſurface of the eye-lids over the anterior portion of the eye. What has been named albuginea cannot properly be conſidered as a coat of the eye, being in fact nothing more than the tendons of the ſtraight muſcles ſpread over ſome parts of the ſclerotica.

The immediate tunics of the eye, which are to be demonſtrated when its partial coverings, and all the other parts with which it is ſurrounded, are removed, are the ſclerotica, cornea, choroides, and retina.

The ſclerotica, which is the exterior coat, is every where white and opaque, and is joined at its anterior edge to another, which has more convexity than any other part of the globe, and being exceedingly tranſparent, is called cornea. Theſe two parts are perfectly different in their ſtructure; ſo that ſome anatomiſts ſuppoſe them to be as diſtinct from each other as a glaſs of a watch is from the caſe into which it is fixed. The ſclerotica is of a compact fibrous ſtructure; the cornea, on the other hand, is compoſed of a great number of laminæ united by cellular membrane. By macerating them in boiling water, they do not ſeparate from each other, as ſome writers have aſſerted; but the cornea ſoon ſoftens, and becomes of a glutinous conſiſtence.

The ancients ſuppoſed the ſclerotica to be a continuation of the dura mater. Morgagni and ſome other modern writers are of the ſame opinion; but this point is diſputed by Winſlow, Haller, Zinn, and others. The truth ſeems to be, that the ſclerotica, though not a production of the dura mater, adheres intimately to that membrane.

The choroides is ſo called becauſe it is finiſhed with a great number of veſſels. It has likewiſe been named avea, on account of its reſemblance to a grape.

The choroides adhere intimately to the ſclerotica round the edge of the cornea; and at the place of this union we may obſerve a little whitiſh areola, named ligamentum ciliare, though it is not of a ligamentous nature.

They who ſuppoſe the choroides to be compoſed of two laminæ, deſcribe the external one as terminating in the ligamentum ciliare, and the internal one as extending farther to form the iris, which is the circle we are able to diſtinguiſh through the cornea: but this part is of a very different ſtructure from the choroides; ſo that ſome late writers have perhaps not improperly conſidered the iris as a diſtinct membrane. It derives its name from the variety of its colours, and is perforated in its middle. This perforation, which is called the pupil or ſight of the eye, is cloſed in the fœtus by a very thin vaſcular membrane. This membrana pupillaris commonly diſappears about the ſeventh month.

On the under ſide of the iris we obſerve many minute fibres, called ciliary proceſſes, which paſs in radii or parallel lines from the circumference to the centre. The contraction and dilatation of the pupil are ſuppoſed to depend on the action of theſe proceſſes. Some have conſidered them as muſcular, but they are not of an irritable nature; others have ſuppoſed them to be filaments of nerves: but their real ſtructure has never yet been clearly aſcertained.

Beſides theſe ciliary proceſſes, anatomiſts uſually ſpeak of the circular fibres of the iris, but no ſuch ſeem to exiſt.

The poſterior ſurface of the iris, the ciliary proceſſes, and part of the tunica choroides, are covered by a black mucus, for the purpoſes of accurate and diſtinct viſion; but the manner in which it is ſecreted, has not been determined.

Immediately under the tunica choroides we find the third and inner coat, called the retina, which ſeems to be merely an expanſion of the pulpy ſubſtance of the optic nerve, extending to the borders of the cryſtalline humour.

The greateſt part of the globe of the eye, within theſe ſeveral tunics, is filled by a very tranſparent and gelatinous humour of conſiderable conſiſtence, which, from its ſuppoſed reſemblance to fuſed glaſs, is called the vitreous humour. It is inveſted by a very fine and delicate membrane, called tunica vitrea, and ſometimes arachnoides. It is ſuppoſed to be compoſed of two laminæ; one of which dips into its ſubſtance, and by dividing the humour into cells adds to its firmneſs. The fore-part of the vitreous humour is a little hollowed, to receive a very white and tranſparent ſubſtance of a firm texture, and of a lenticular and ſomewhat convex ſhape, named the cryſtalline humour. It is included in a capſula, which ſeems to be formed by a ſeparation of the two laminæ of the tunica vitrea.

The fore-part of the eye is filled by a very thin and tranſparent fluid, named the aqueous humour, which occupies all the ſpace between the cryſtalline and the prominent cornea. That part of the choroides which is called the iris, and which comes forward to form the pupil, appears to be ſuſpended as it were in this humour, and has occaſioned this portion of the eye to be diſtinguiſhed into two parts. One of theſe, which is the little ſpace between the anterior ſurface of the cryſtalline and the iris, is called the poſterior chamber; and the other, which is the ſpace between the iris and the cornea, is called the anterior chamber of the eye. Both theſe ſpaces are completely filled with the aqueous humour.

The eye receives its arteries from the internal carotid through the foramina optica; and its veins paſs through the foramina lacera, and empty themſelves into the lateral ſinuſes. Some of the ramifications of theſe veſſels appear on the inner ſurface of the iris, where they are ſeen to make every minute convolutions, which are ſufficiently remarkable to be diſtinguiſhed by the name of circulus arterioſus, though perhaps improperly, as they are chiefly branches of veins.

The optic nerve paſſes in at the poſterior part of the eye, in a conſiderable trunk, to be expanded for the purpoſes of viſion, of which it is now univerſally ſuppoſed to be the immediate ſeat.

The humours of the eye, together with the cornea, are calculated to refract and converge the rays of light in ſuch a manner as to form at the bottom of the eye a diſtinct image of the object we look at; and the point where theſe rays meet is called the focus of the eye. On the retina, as in a camera obſcura, the object is painted in an inverted poſition; and it is only by habit that we are enabled to judge of its true ſituation, and likewiſe of its diſtance and magnitude.

In order to paint objects diſtinctly on the retina, the cornea is required to have ſuch a degree of convexity, that the rays of light may be collected at a certain point, ſo as to terminate exactly on the retina. If the cornea is too prominent, the rays, by diverging too ſoon, will be united before they reach the retina, as is the caſe with near-ſighted people or myopes; and on the contrary, if it is not ſufficiently convex, the rays will not be perfectly united when they reach the backpart of the eye; and this happens to long-ſighted people or preſbi, being found conſtantly to take place as we approach to old age, when the eye gradually flattens. Theſe defects are to be ſupplied by means of glaſſes. He who has too prominent an eye, will find his viſion improved by means of a concave glaſs; and upon the ſame principles, a convex glaſs will be found uſeful to a perſon whoſe eye is naturally too flat.

Explanation of the PLATE *on the* ORGANS OF SENSE.

A, A, A, Extreme branches of the meſenteric vein. B, The great meſenteric vein about to enter the liver. C, C, C, Its extreme branches forming vena portæ.

In this Syſtem I have introduced Eight Anatomical Tables of the Human Body, containing the principal Parts of the Skeleton and Muſcles, repreſented in the large Tables of Albinus, to which are added conciſe explanations by Mr. John Innes, late Diſſector to Dr. Monro, two of which is deſcribed in Oſteology, Part II. Section XIV. *and the remaining Six in the following Section. For practitioners and thoſe uninformed in this art, I could not preſent them with better tables, being abridged of that multiplicity of references which abound in the original tables of Albinus. Having preſented the public with Innes's Abridgements of Albinus, I ſhall make the following extract from his work.*

JOHN HALL.

" The tables of Albinus, though accurate and complete, are not, perhaps, on account of their ſize, the prolixity of the deſcriptions, and the number of references, ſo fully ſuited to the purpoſes of private diſſection as could be wiſhed. To remedy this inconvenience, I have copied eight of Albinus's tables on a ſmaller ſcale. The two firſt contain a fore and back view of the ſkeleton; and the other ſix are repreſentations of the muſcles. To each plate I have prefixed an explanation; and I have avoided, as much as was conſiſtent with perſpicuity, loading the figures with an unneceſſary quantity of referring letters. For this purpoſe I have throughout made uſe of one alphabet only. To prevent the defacing of the muſcles, and to enable the learner to diſtinguiſh them without the aſſiſtance of references, the figures are only lettered on one ſide. If this work be of uſe in facilitating Anatomical knowledge, it will give the greateſt pleaſure to, Gentlemen, Your humble ſervant,

JOHN INNES."

EXPLANATION OF THE FIRST PLATE ON MYOLOGY.

FIGURE I.

This Table repreſents the firſt Layer of Muſcles ſituated on the anterior Part of the whole Body, immediately under the common Teguments, and tendinous Faſciae.

MUSCLES SITUATED ON THE HEAD AND NECK.

a, The anterior fleſhy belly of the occipito-frontalis ſituated on os frontis. Above *a*, the tendinous aponeuroſis of the occipito-frontalis, covering the upper part of the parietal bones. *b*, Attollens aurem. Under it, the tendinous aponeuroſis covering the temporal muſcle. Anterior auris between *c* and the ear. *c*, Orbicularis palpebrarum. Its tendon is ſeen at the inner canthus, fixed to the naſal proceſs of the ſuperior maxillary bone. Levator labii ſuperioris alaeque naſi. Seen divided into two portions running down along the ſide of the noſe, and on the out ſide of it the levator anguli oris. Next this, the zygomaticus minor. Further outwards, zygomaticus major. On the ala and tip of the noſe, the compreſſor naris. *d*, Depreſſor anguli oris. And beneath it, a portion of the depreſſor labii inferioris. *e*, Orbicularis oris. *f*, Platyſma-myoides. Behind *f*, the ſterno-cleido-maſtoidæus is ſeen through the platyſma-myoides.

TRUNK.

a, Pectoralis major. The upper part of it is covered by the origin of the platyſma-myoides. *b*, Serratus magnus. The other portions reſemble this. *c*, Latiſſimus dorſi. *d*, Obliquus externus deſcendens. *e*, Linea ſemilunaris. *f*, Linea alba. Below *f*, umbilicus. Between *e* and *f*, the rectus abdominis; and, at the inferior part of the linea alba, oppoſite to *g*, the pyramydales appear through the tendons of the oblique muſcles. *g*, Ring of the external oblique muſcle; with the ſpermatic cord, paſſing through it, and covered by the cremaſter muſcle.

SUPERIOR EXTREMITY.

a, Deltoides. Above the clavicle, a portion of the trapezius is ſeen. *b*, Biceps flexor cubiti. At the bending of the arm are ſeen its tendon going towards the radius, and the part, from which the tendinous aponeuroſis that covers the fore-arm, cut off. On the inſide of the biceps, part of the triceps extenſor cubiti, and, on the outſide, part of the brachialis internus. *c*, Supinator radii longus. *d*, Pronator teres. *e*, Palmaris longus. *f*, Palmaris brevis. On the palm of the hand, the aponeuroſis palmaris is ſeen extended from the annular ligament at the wriſt to the roots of the metacarpal bones of the four fingers. *g*, Flexor carpi radialis. *h*, Part of the flexor ſublimus perforatus. *i*, Inſertion of the flexor carpi ulnaris. *k*, Abductor pollicis.

INFERIOR EXTREMITY.

r, Tenſor vaginae femoris, the vagina or tendinous faſcia being cut off. On the outſide of it, a portion of the glutaeus maximus. *b*, Part of the iliacus internus. On the inſide of it, between *b* and *c*, part of the pſoas magnus. *c*, Pectinalis. *d*, Triceps longus. *e*, Gracilis. *f*, Sartorius. *g*, Rectus cruris. Its tendon is ſeen inſerted into the patella, from which a ſtrong tendon is ſent to be fixed to the tubercle of the tibia. *h*, Vaſtus externus. *i*, Vaſtus internus. *k*, Tibialis anticus. *l*, Peronæus longus. On the outſide of it, a portion of the ſolæus. *m*, Extenſor longus digitorum pedis, with the peronæus tertius, and extenſor proprius pollicis pedis. *n*, Gaſtrocnemius externus, ſeu Gemellus. *o*, Solæus. *p*, Ligamentum tarſi annulare. *q*, Abductor pollicis pedis.

FIGURE II.

This Table repreſents a back View of the Muſcles, which are immediately ſituated below the common Integuments.

HEAD AND NECK.

a, Part of the occipito-frontalis muſcle, with its aponeuroſis. *b*, Attollens aurem. *c*, Anterior auris. *d*, Retrahentes auris.

TRUNK.

a, Trapezius, ſeu cucularis. *b*, Its tendinous joining with its fellow in the nape of the neck, which is called ligamentum nuchae, ſeu colli. *c*, The fleſhy belly of the latiſſimns dorſi. *d*, The tendon of the latiſſimus dorſi, which ariſes in common with the ſerratus poſticus inferior. *e*, Part of the obliquus exteruus abdominis.

SUPERIOR EXTREMITY.

a, Deltoides. *b*, Infra ſpinatus, with a portion of the teres minor and major below it. *c*, Triceps extenſor cubiti. Its tendon is ſeen inſerted into the head of the ulna, called olecranon; and on the inſide of it, the anconæus. *d*, Extenſor carpi radialis longior, covered by a portion of the ſupinator radii longus; and under it, a portion of the extenſor carpi radialis brevior. *e*, Extenſor digitorum communis manus, which ſplits into four tendons, and paſs, with the indicator, under the ligamentum carpi annulare externum, at the extremities of the metacarpal bones, under ligaments proper to themſelves, and are loſt in a broad tendon, which covers the back of the four fingers. *f*, Extenſor oſſis metacarpi pollicis manus. *g*, Extenſor primi internodii pollicis manus. *h*, Extenſor ſecundi internodii pollicis manus. *i*, Extenſor carpi ulnaris. *k*, Part of the flexor carpi ulnaris. Under it, part of the flexor profundus perforatus. And on the inſide, part of the flexor ſublimus perforatus, which are more diſtinctly ſeen on the right fore-arm. Likewiſe, on the right hand, are ſeen part of the abductor pollicis manus, abductor minimi digiti manus, and the aponeuroſis palmaris.

INFERIOR EXTREMITY.

a, Glutæus maximus. *b*, Part of the glutæus medius. *c*, Part of the tenſor vaginæ femoris. *d*, Vaſtus externus. *e*, The long head of the biceps flexor cruris. And beneath it, *f*, Part of the ſhort head. *g*, Semitendinoſus. And beneath it, on each ſide, a portion of the ſemimembranoſus is ſeen. *h*, Gracilis. On the outſide of it, a portion of the adductor magnus is ſeen. *i*, A ſmall part of the vaſtus internus. *k*, Gaſtrocnemius externus, ſeu gemellus. And within its outer head, a portion of the plantaris. *l*, Solæus ſeu gaſtrocnemius internus. *m*, Tendo-achillis, with the plantaris. *n*, Peronæus longus. *o*, Peronæus brevis, between it and the tendo-achillis, a portion of the flexor longus digitorum pedis. *p*, Tendons of the extenſor longus digitorum pedis, with the peronæus tertius paſſing under the ligamentum tarſi annulare; and the flexor brevis digitorum pedis is ſeen beneath them. *q*, Abductor minimi digiti pedis, and above it the tendons of the peronæus longus and brevis, paſſing under proper ligaments of their own.

Published according to Act of Parliament by C. Cooke No. 17 Paternoster Row Novr. 14. 1788.

FIGURE III.

This Table repreſents the Second Layer of Muſcles on the anterior Part of the whole Body.

MUSCLES SITUATED ON THE HEAD AND NECK.

a, Corrugator ſupercilii. *b*, Temporalis. *c*, Maſſeter. *d*, Levator anguli oris. *e*, Buccinator. *f*, Orbicularis oris. Oppoſite to the right ala niſi, the portion of this muſcle which Albinus names Naſalis labii ſuperioris. *g*, Depreſſor labii inferioris. *h*, Sterno-cleido-maſtoidæus, which is ſeen below, ariſing from the ſternum and clavicle, by two heads. *i*, Sterno-hyoidæus. On the outſide of it, the omo-hyoidæus. Further out, a portion of the hyo-thyroidæus. *k*, Levator ſcapulæ.

TRUNK.

a, Subclavius. *b*, Pectoralis minor. *c*, Serratus magnus. *d*, Rectus abdominis, divided into ſeveral fleſhy portions by its tendinous interſections. *e*, Pyramidalis. *f*, Obliquus aſcendens internus. *g*, Spermatic cord, with the origin of the cremaſter muſcle.

SUPERIOR EXTREMITY.

a, Biceps flexor cubiti. *b*, Short head of the biceps. Beneath the upper part of it, a portion of the coracobrachialis. Beneath the under part, a portion of the brachialis internus. *c*, Long head of the biceps. At the bending of the arm, the tendon of the biceps, and the place where the tendinous aponeuroſis was cut from it, are ſeen. *d*, Extenſor carpi radialis longior. Beneath it a portion of the extenſor carpi radialis brevior. *e*, Flexor ſublimus perforatus. *f*, Inſertion of the extenſor carpi ulnaris. *g*, Extenſors of the thumb. *h*, Opponens pollicis. On the inſide of it, a portion of the flexor pollicis brevis. *i*, Tendon of the flexor longus pollicis manus, after paſſing through the flexor brevis pollicis manus. *k*, Abductor minimi digiti manus. *l*, Flexor parvus minimi digiti manus. *m*, Ligamentum carpi annulare.

INFERIOR EXTREMITY.

a, Iliacus internus. Between *a* and *b*, part of the pſoas magnus. *b*, Pectinalis, *c*, Triceps longus. *d*, Gracilis. *e*, Rectus cruris cut off near its origin. *f*, Tendon of the rectus cruris cut off above the patella, from which a ſtrong tendon is ſent to be inſerted into the tubercle of the tibia. *g*, Portion of the glutæus medius. On the inſide of it, part of the glutæus minimus. *h*, Vaſtus internus. *i*, Vaſtus externus. *k*, Cruræus. *l*, Inſertion of the biceps flexor cruris into the fibula. *m*, Tendons of the gracilis and ſemitendinoſus inſerted into the tibia. *n*, Solæus. *o*, Peronæus longus. *p*, Extenſor longus digitorum, with the peronæus tertius on the outſide, and extenſor pollicis proprius on the inſide. *q*, Solæus. *r*, Flexor longus digitorum. *ſ*, Tendons of the tibialis poſticus and flexor longus digitorum pedis. *t*, Flexor brevis digitorum pedis.

FIGURE IV.

This Table repreſents the ſecond Layer of the Muſcles on the back Part of the Body.

HEAD AND NECK.

a, Temporalis; its tendon is ſeen paſſing below zygoma. *b*, Maſſeter. *c*, Splenius capitis et colli. *d*, Portion of the complexus. *e*, Levator ſcapulae, ſeu muſculus patientiae.

TRUNK.

a, Rhomboides major. *b*, Rhomboides minor. And immediately above it the upper edge of the ſerratus poſticus ſuperior is ſeen. *c*, The ſerratus poſticus ſuperior on the right ſide. *d*, Serratus poſticus inferior. *e*, Part of the ſpinalis dorſi. *f*, Part of the longiſſimus dorſi. *g*, Part of the ſacrolumbalis. *h*, Serratus magnus. *i*, The broad tendon, by which the latiſſimus dorſi begins, and from which the tendon of the ſerratus poſticus inferior is inſeparable. *k*, Part of the obliquus internus aſcendens abdominis. *l*, The ſpincter ani, fixed to the point of the os coccigis; at the ſide of which the coccygaeus, a portion of the levator ani are ſeen, and lower down, oppoſite to *l*, part of the tranſverſalis penis.

SUPERIOR EXTREMITY.

a, Supra ſpinatus. *b*, Infra ſpinatus. *c*, Teres minor. *d*, Teres major. *e*, Triceps extenſor cubiti. *f*, Its head, called longus. *g*, The bervis. And, *h*, A ſmall portion of the third head, named brachialis externus. *i*, The tendon of the triceps, inſerted into the olecranon. *k*, Part of the brachialis internus. *l*, Anconaeus, which ſeems to be continued from that part of the brachialis externus immediately above it. *m*, Extenſor carpi radialis longior; and beneath it the brevior; both are ſeen at the wriſt, inſerted into the metacarpal bones of the fore and middle fingers. *n*, Flexor carpi ulnaris. *o*, Part of the ſupinator radii brevis. *p*, Extenſor oſſis metacarpi pollices manus. *q*, Extenſor primi internodii pollicis manus. *r*, Extenſor ſecundi internodii pollicis manus. *ſ*, Indicator, inſerted into the root of the firſt joint of the fore-finger. *t*, One of the three external interoſſei manus. The other two are diſtinctly ſeen without letters. *u*, One of the tendons of the extenſors of the fingers cut; and the ſame is ſeen in each of the other three fingers, joining with the tendons and aponeuroſes of the interoſſei and lumbricales, and ſpread upon the back of the fingers.

N. B. On the right hand, part of the flexors of the fingers, the abductor pollicis, and minimi digiti, are ſeen.

INFERIOR EXTREMITY.

a, Glutæus medius. *b*, Pyriformis. *c*, The two muſcles called Gemini, between which the tendon of the obturator internus paſſes over the tuberoſity of the os iſchium; and its fleſhy belly is ſeen within the pelvis, partly covered by the coccygæus and levator ani. *d*, Quadratus femoris. *e*, Vaſtus externus. *f*, *f*, Parts of the triceps magnus. *g*, Long head of the triceps flexor cruris; and beneath it part of the ſhort head is ſeen. *h*, Semitendinoſus, and beneath it parts of the ſemimembranoſus are ſeen on each ſide of it. *i*, Gracilis. *k*, A ſmall portion of the vaſtus internus. *l*, Poplitæus. *m*, the fleſhy belly of the plantaris; and its long ſlender tendon is ſeen paſſing over the inſide of the ſolæus. *n*, Solæus. *o*, The place where the tendon of the gemellus was cut off; but the fleſh of the ſolæus runs further down. *p*, Tendo-achillis, with the plantaris. *q*, Peronæus longus, paſſing at the outer angle to the ſole of the foot; beneath it, the peronæus brevis to the root of the metatarſal bone of the little toe; and between it and the tendo-achillis, a portion of the flexor longus digitorum pedis. *r*, Tendons of the extenſor longus dictorum pedis, with the peronæus tertius; and beneath theſe, the extenſor brevis dictorum pedis. *ſ*, Flexor brevis minimi digiti pedis.

EXPLANATION OF THE SECOND PLATE ON MYOLOGY.

FIGURE I.

This Table repreſents the third Layer of Muſcles, with ſome of the Ligaments, Cartilages, and naked Bones on the anterior Part of the whole Body.

a, Depreſſor labii ſuperioris alæque naſi. *b*, Orbicularis oris, afeer moſt of the muſcles, which are fixed to it, and aſſiſt to form it, have been taken away. *c*, Buccinator. Above *c*, part of the pterygoidæus externus is ſeen paſſing behind the coronoid proceſs of the lower jaw. *d*, Levator labii inferiors. *e*, Sterno-thyroidæus. Immediately above, and ſeemingly the continuation of it, the Hyo-thyroidæus. *f*, Scalenus medius. Contiguous to it, on the inſide, Scalenus anticus. Above it, a portion of the Trachelo-maſtoidæus. Between the ſcalenus anticus, and ſterno-thyroidæus, and hyo-thyroidæus, the rectus capitis anterius major, and longus colli.

TRUNK.

a, Third row of external intercoſtal muſcles. The reſt appear in the ſame manner between the other ribs. *b*, Third row of internal intercoſtal muſcles. The reſt appear between the other ribs. *c*, Tranſverſalis abdominis. *d*, The place from which the inferior part of the tendon of the tranſverſalis, that paſſes before the rectus and pyramidalis muſcles, is cut off. Between theſe portions of each ſide, the peritonæum is laid bare, and the ligaments of the bladder which were formerly the umbilical arteries and urachus. Between this portion and os pubis, the ſpermatic cord is ſeen cut. *e*, The inferior edge of the upper part of the tendon of the tranſverſalis, which paſſes behind the rectus, and immediately adheres to the peritonæum. *f*, The anterior lamella of the internal oblique, which joined the tendon of the external to paſs over the rectus. Between *f* and *g*, the poſterior lamella of the internal oblique, joining with the tendon of the tranſverſalis, to paſs behind the rectus, *g*, the place at the linea alba, from which the tendon of the external oblique, aud interior lamella of the internal, were cut off. At *g*, Umbilicus.

SUPERIOR EXTREMITY.

a, Subſcapularis. *q*, Teres minor. *c*, Coraco-brachialis. The part from which the ſhort head of the biceps flexor cubiti was cut off from it, is ſeen at its upper end. *d*, Brachialis internus. *e*, Brachialis externus, or third head of the triceps. *f*, Extenſor carpi radialis longior, and with it the extenſor carpi radialis brevior. Both theſe are diſtinctly ſeen in the right hand. Between the tendon of the brachialis internus, and extenſor radialis, the ſupinator radii brevis is ſeen. *g*, Flexor longus pollices manus, with the fleſhy portion of it, which ariſes from the internal condyle of the os humeri. *h*, Flexor profundus perforans, which ſplits into four tendons, which paſs under the ligamentum carpi annulare. *i*, Pronator quadratus. *k*, Adductor minimi digiti manus. *l*, One of the lumbricales. The other three appear in the ſame manner, along the tendons of the flexor profundus. Behind theſe, the internal interoſſei are ſeen.

INFERIOR EXTREMITY.

a, Glutæus minimus. *b*, Iliacus internus. On the inſide of it, betwetn *b* and *c*, the pſoas magnus. *c*, Obturator externus. *d*, Adductor brevis femoris. *e*, Adductor magnus femoris. *f*, Gracilis, which is Seen inſerted into the inſide of the head of the tibia. *g*, The ſhort head of the biceps flexor cruris. *h* Peronæus longus. *i*, Peronæus brevis. Between theſe two peronæi and tibia, the tibialis poſticus is ſeen. *k*, Tendon of the tibialis poſticus, coveriug the tendon of the flexor longus digitorum pedis. *l*, Extenſor brevis digitorum pedis.

FIGURE II.

This Table repreſents the third Layer of Muſcles on the poſterior Part of the Body, with ſome of the Ligaments and naked Bones.

MUSCLES ON THE HEAD AND NECK.

a, Part of the buccinator. *b*, Complexus. *c*, Trachelo-maſtoidæus; on the outſide of it the tranſverſalis colli. *d*, Scalenus medius. *e*, Scalenus poſticus.

TRUNK.

a, Spinalis dorſi; and beneath it the multifidus ſpinæ. *b*, Longiſſimus dorſi, which ſends off a fleſhy ſlip to the trachelo-maſtoidæus. *c*, Sacro-lumbalis, with the cervicalis deſcendens ſent off from it along the ſide of the neck, and outſide of the tranſverſalis colli. *d*, Semiſpinalis dorſi. *e*, Tranſverſalis abominis.

N. B. The ſpaces between the ſpinous proceſſes of the vertebræ have muſcular faſciculi between them, particularly thoſe of the neck, and are named interſpinales colli, dorſi, and lumborum; but thoſe of the back ſeem to be tendinous and ligamentous.

SUPERIOR EXTREMITY.

a, Teres major. *b*, Part of the coraco-brachialis. *c*, Part of the brachialis internus. *d*, The third head of the triceps extenſor cubiti, called brachialis externus, after the longus and brevis have been cut off. *e*, Extenſor radialis longior. *f*, Extenſor radialis brevior. *g*, Part of the flexor profundus perforans. *h*, Supinator radii brevis. *i*, Part of the adductor pollicis manus. *k*, One of the three external interoſſei; the other two may be eaſily diſtinguiſhed without letters. *l*, Tendons of the extenſors of the fingers, joining with thoſe of the lumbricales and interoſſei, which form a tendinous expanſion on the back of the four fingers.

N. B. On the right hand, part of the flexors of the fingers and thumb; part of the adductor pollicis, and the whole of the adductor minimi digiti, are ſeen.

INFERIOR EXTREMITY.

a, Glutæus minimus. *b*, Obturator internus, its fleſhy belly is ſeen within the pelvis. Beneath *b*, the tendon of the obturator externus. *c*, Semimembranoſus. *d*, The ſhort head of the biceps flexor cruris. *e*, Triceps magnus. *f*, Gracilis. In the ham, the origins of the two heads of the gaſtrocnemius externus and plantaris, are ſeen. *g*, Poplitæus. *h*, Tibialis poſticus. *i*, Flexor longus digitorum pedis. *k*, Flexor pollicis longus. *l*, Peronæus longus, running down to be inſerted into the metatarſal bone of the little toe. Beneath it, the peronæus brevis, paſſing to the ſole of the foot. *m*, Extenſor brevis digitorum pedis. *n*, Part of the flexor longus digitorum pedis.

FIGURE III.

Diaphragm ſeen within the Abdomen, where it forms a conſiderable Concavity.

A A, Its ſuperior radiated portion. B B, Its two cruræ or inferior portion. C, Centrum tendinoſum. D, Opening by which the inferior vena cava paſſes to the heart. E, The ſlit through which the oeſophagus paſſes to the ſtomach. F. The aorta and thoracic duct paſſing into the thorax between its two cruræ.

FIGURE IV.

Shews the Pteregoid and ſome other Internal Muſcles.

A, Pteregoideus externus. B, Pteregoideus internus. C, Lower jaw. D, Occiput. E, Cervical vertibræ.

FIGURE V.

Shews the Poſterior Muſcles of the Pharynx.

A, Os occipitis. B, Œſophagus. C, Intermediate muſcles.

FIGURE VI, VII, VIII.

Shews the Poſterior Part of the Pharynx in different Views, after the Removal of ſome of the Muſcles.

FIGURE IX, X, XI, XII.

Exhibits a Poſterior View of the Pharynx and Larynx, after the Removal of all the Poſterior Muſcles of the Pharynx.

FIGURE XIII, XIV, XV, XVI, XVII.

Exhibit the three Laminæ of Muſcles which are found in the Sole of the Foot, as well as the Tendons of the Flexor Muſcles of the Toes, which are ſituated on the Leg, to give a more clear View of the Muſcles on this Part of the Body, than can be ſeen in the whole Figures.

Fig. 13. The tendons and muſcles on the ſole of the foot, immediately under the integuments.

Fig. 14. The firſt order of muſcles after removing the tendinous expanſion.

Fig. 15. The ſecond order of muſcles.

Fig. 16. The third order of muſcles removed, which ſhew the tendons of the flexors.

Fig. 17. The fourth order of muſcles removed, ſhewing the tendon of tibralis porticus, &c.

The Drawings in this Syſtem have been done under my Direction by Mr. Birnie, of Greſſe ſtreet, Anatomical Draftſman to the late Dr. William Hunter of Windmill ſtreet, whoſe productions accompany moſt of the preſent Anatomical Publications of any conſequence.

The Engravings in this Syſtem are nearly all finiſhed; thoſe which I have ſeen, I will venture to aſſert infinitely ſurpaſs any I have ever ſeen in any Periodical Publication whatever, both with reſpect to truth *of Drawing, and* beauty *of Engraving.*

In order to ſhew the compariſon between the Human and Brute Skeleton, I have ſupplied Mr. Cooke, the publiſher of this Work, with a Skeleton of a Bear and Monkey, a repreſentation of which will be introduced in this Work, and brought under the head of Comparative ANATOMY.

TO THE FACULTY IN GENERAL, AND TO STUDENTS OF ANATOMY IN PARTICULAR.

THE foregoing compendium of Anatomy I have compiled, as I thought would be moſt conducive to the improvement of thoſe who ſhould honour it with an attentive peruſal; at the ſame time having in view the generality of thoſe numerous readers who have diſtinguiſhed the NEW ROYAL ENCYCLOPŒDIA with their patronage.

It is ſo arranged, that where an examination of dead bodies can be obtained, the mode of ſuch examination will be found moſt advantageouſly pointed out; and the zealous ſtudent may proceed by the ſhorteſt way, to confirm his mind in Anatomical knowledge; thereby ſaving much time in the examination of authors, and collection of the ſyſtem; which is no where to be found in a ſimilar mode of arrangement, to that of the preſent conciſe plan.

According to this order, I have, for ſeveral years, diſſected bodies, and demonſtrated their ſtructure, in two regular courſes of lectures that have been given during each winter. In which courſes I have moſt ardently ſtrove to concentrate real Anatomical knowledge, by bringing together every thing eſſential, and expunging every thing merely hypothetical; wiſhing moſt fervently to adopt my mode of teaching, to the generality of ſtudents that viſit this metropolis; and to give real information to them, rather than diſplay my own abilities in theoretical diſquiſitions.

The late Dr. Hunter taught Anatomy in this way, till within a few years of his death; and may be ſaid to have raiſed his fame, to its highly diſtinguiſhed eminence, by thus diſpenſing knowledge in the eaſieſt manner! To the great diſadvantage of many ſtudents, in the latter part of his life, he doubled the length of his courſe, which increaſed it in extent far beyond any other courſe of Anatomy given in Europe. A lecture continuing two hours a day for eight months, might allow the communication of an immenſity of knowledge, and eſpecially when confined to the demonſtration of one ſcience, many elevated medical characters have thought this mode of teaching Anatomy too profuſe, and ill adapted to the inſtruction of the generality of ſtudents! Students in Anatomy very ſeldom want ſo minute a diſplay of the ſcience, eſpecially thoſe who come to town in the middle of the winter, and who muſt then neceſſarily begin in the middle of a courſe.

Dr. Hunter felt the force of theſe arguments, and could not deny them. I have heard him acknowledge, that there might be ſome ſtudents whom this alteration would materially affect. From this alteration in Dr. Hunter's plan, I was induced to teach Anatomy; and as the ſame plan has been continued ſince his death, I think it a ſervice to the public, to perſevere, to afford an opportunity to ſtudents of ſeeing the human body fully demonſtrated twice in each winter; that thoſe who come to town at Chriſtmas, may ſtill go through a complete courſe of Anatomy.

The following is the arrangement of my plan of teaching:—

Firſt, To give two courſes in the winter, each conſiſting of about one hundred lectures.

Secondly, The firſt courſe to begin early in October, and continue till after the middle of January; and then the ſecond courſe to commence and conclude by the end of May.

Thirdly, To omit nothing material in Anatomy, Phyſiology, or Surgery, in this courſe; but at the ſame time to avoid all unneceſſary prolixity.

Fourthly, To give opportunities for the diſſection of bodies, during the winter, the better to confirm thoſe ideas that may be obtained from the lectures.

☞ *For terms of attendance, ſee the Wrappers to No.* 19, *of this Work.*

Broad ſtreet, No. 41, *Golden Square,* JOHN HALL.

I ſhould conſider myſelf highly remiſs, was I to omit this Opportunity of making my public Acknowledgments to Dr. Birch, *of Eſſex Street, Strand,* Dr. Oldroyd, *of Red-Lion Street, Clerkenwell, and* Dr. Baker, *of Saliſbury Square, Fleet Street, for th eliberal Aſſiſtance they have contributed in this Syſtem, by the Loan of Books, Drawings, and Prints. I therefore beg Leave to ſubſcribe myſelf their*

Very much obliged,

Pater-noſter Row. *And devoted humble Servant,*

C. COOKE.

BRITISH 18 MR 63 MUSEUM

ANATRON, or NATRON, in natural hiſtory, implies a kind of ſalt petre found in Egypt, reſembling ſal-ammoniac in taſte. This word alſo imports the ſalt ſcum of glaſs in its ſtate of fuſion. It likewiſe denotes the nitrous juice condenſed in vaults, arches, and other ſubterraneous places.

ANATROPE, in medical definition, implies a diſorder of the ſtomach, which occaſions a vomiting and loſs of appetite.

ANAUDIA, in natural hiſtory, implies an incapacity of ſpeech, i. e. dumbneſs.

ANAX, in mythology, denotes a hero, or demi-god.

ANAXIMANDRIANS, in the hiſtory of philoſophy, the followers of Anaximander; the moſt ancient of the philoſophical atheiſts, who admitted of no other ſubſtance in nature but matter.

ANBERKEND, in the eaſtern language, a celebrated book of the Brachmans, wherein the Indian philoſophy and religion are contained. The anbertkend is divided into 50 beths, or diſcourſes, each of which conſiſts of ten chapters. It has been tranſlated from the original Indian into Arabic, under the title of Morat al Maani, q. d. the marrow of intelligence.

ANBURY, or AMBURY, among farriers, implies a kind of ſpongy wort, or wen, full of blood, growing upon any part of a horſe.

ANCESTORS, thoſe from whom a perſon is deſcended in a ſtraight line. The word is derived from the Latin *anceſſor*, contracted from *anteceſſor*, q. d. goer before.

ANCESTREL, in law, implies any thing which deſcends by a regular line from ones anceſtors.

ANCHILOPS, *αγκυλη*, contraction, and *ωψ*, eye; in medicine denotes an abſceſs, or collection of matter, between the great angle of the eye and the noſe: and if ſuffered to remain too long, it degenerates, the ſtagnating humours corrupt, and an ulcer is produced. When the tumor is broke, and the tears flow involuntarily, whilſt the os lacrymale is not carious, it is an ægylops; but when the ulcer is of a long ſtanding, deep, fetid, and the os lacrymale becomes carious, it is a fiſtula. The cure is by reſtriction and exciſion, tying it at the root on the glandula lacrymalis, and, when ready, cutting it off.

ANCHOR, *Anchora*, Lat. from *αγκυρα*, Greek, a heavy, ſtrong, crooked inſtrument of iron, dropped from a ſhip into the bottom of the water, to retain her in a convenient ſtation in a harbour, road, or river.

The ancient anchors were of ſtone; and ſometimes of wood, to which a great quantity of lead was uſually fixed. In ſome places, baſkets full of ſtones, and ſacks filled with ſand, were employed for the ſame uſe. All theſe were let down by cords into the ſea, and by their weight ſtayed the courſe of the ſhip. Afterwards they were compoſed of iron, and furniſhed with teeth, which, being faſtened to the bottom of the ſea, preſerved the veſſel immoveable; whence *οδοντης* and *dentes* are frequently taken for anchors in the Greek and Latin poets.

At firſt the iron anchor had only one tooth, whence anchors were called *ετεροςομοι*; but in a ſhort time the ſecond was added by Eupalamus, or Anacharſis, the Scythian philoſopher. The anchors with two teeth were called *αμφιβολοι*, or *αμφιςομοι*; and from ancient monuments appear to have been much the ſame with thoſe uſed in our days, only the tranſverſe piece of wood upon their handles (the ſtock) is wanting in all of them.

Modern anchors are contrived ſo as to ſink into the ground as ſoon as they reach it, and to hold a great ſtrain before they can be looſened or diſlodged from their ſtation. They are compoſed of a ſhank, a ſtock, a ring, and two arms with their flukes. The ſtock, which is a long piece of timber fixed acroſs the ſhank, ſerves to guide the flukes in a direction perpendicular to the ſurface of the ground; ſo that one of them ſinks into it by its own weight as ſoon as it falls, and is ſtill preſerved ſteadily in that poſition by the ſtock, which, together with the ſhank, lies flat on the bottom. In this ſituation it muſt neceſſarily ſuſtain a great effort before it can be dragged through the earth horizontally. And this can only be effected by the violence of the wind and tide, increaſed by the turbulence of the ſea, and acting upon the ſhip, ſo as to ſtretch the cable to its utmoſt tenſion, which may diſlodge the anchor from its bed, more eſpecially if the ground be ſoft, oozy, or rocky. When the anchor is thus diſplaced, it is ſaid, in the ſea-phraſe, to *come home*.

At ANCHOR; the ſituation of a ſhip which rides by her anchor in a road or haven.

To fiſh the ANCHOR; to draw up the flukes upon the ſhip's ſide after it is catted.

To ſteer the ſhip to her ANCHOR, is to ſteer the ſhip's head towards the place where the anchor lies, when they are heaving the cable into the ſhip; ſo that the cable may enter the houſe with leſs reſiſtance, and the ſhip advance towards the anchor with greater facility.

ANCHOR-GROUND, is a bottom which is neither too deep, too ſhallow, or rocky.

ANCHORS, in heraldry, are emblems of hope, and are taken for ſuch in a ſpiritual, as well as a temporal ſenſe.

ANCHORAGE, in law, is a duty upon ſhips for the uſe of the port or harbour where they caſt anchor.

ANCHOVY, in ichthyology, the Engliſh name of the clupea encraſicolus.

ANCHOVY-PEAR, the ſame as GRIAS.

ANCHUSA, ALKANET or BUGLOSS, a genus of the monogynia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 41ſt order, aſperifoliæ. For the characters ſee Syſtem of BOTANY. There are eight ſpecies.

1. The officinalis, or greater garden bugloſs, is a native of France, and of the warmer parts of Europe, but will thrive well enough in Britain; but the roots ſeldom continue longer than two years in this country, unleſs they happen to grow in rubbiſh, or out of an old wall, where they will live three or four years.

2. The anguſtifolia, or perennial wild borage, grows to the height of two feet when cultivated in gardens; but in thoſe places where it grows wild, is ſeldom more than a foot and an half high.

3. The undulata, or Portugal bugloſs, is a biennial plant, which grows to the height of two feet, and ſends out many lateral branches.

4. The orientalis, or eaſtern bugloſs, is a native of the Levant, but hardy enough to bear the open air in Britain, if it hath a dry ſandy ſoil.

5. The virginiana, or puccoon, grows naturally in the woods of North America.

6. The ſempervirens, or evergreen borage, is a very hardy perennial plant, with weak trailing branches. It grows naturally in ſome parts of Great Britain.

7. The cretica, or warted bugloſs of Crete, is a low trailing annual plant, whoſe branches ſeldom extend more than ſix inches.

8. The tinctoria, or true alkanet, grows naturally in the Levant, but is equally hardy with the firſt ſpecies.

All the ſpecies of anchuſa may be propagated by ſeeds.

The flowers of the firſt ſpecies have obtained the name of cordial flowers; they moderately cool and ſoften, without offending, the palate or ſtomach.

ANCHYLOBLEPHARON, the ſame as ANCYLOBLEPHARON.

ANCHYLOPS, the ſame as ANCHILOPS.

ANCHYLOSIS, the ſame as ANCYLOSIS.

ANCIENT, or ANTIENT, a term applied to things which exiſted long ago; thus we ſay, ancient nations, ancient cuſtoms, &c.

ANCIENT, in a military ſenſe, denotes either the enſign or colours.

ANCIENT, in ſhips of war, the ſtreamer or flag borne in the ſtern.

ANCIENT DEMESNE, in Engliſh law, ſignifies a tenure, by which all manors belonging to the crown in William the conqueror's and St. Edward's time were held. The numbers, names, &c. hereof were entered by the Conqueror, in a book called Domeſday Book, yet remaining in the Exchequer; ſo that ſuch lands, as by that book appeared to have belonged to the crown at that time, are called ancient demeſne. The tenants are of two ſorts; one of which hold their lands frankly by charter; the other by copy of court-roll, or by the verge, at the will of the lord, according to the cuſtom of the manor.

The advantages of this tenure are, 1. That tenants holding by charter cannot be rightfully impleaded out of their manor; and when they are, they may abate the writ, by pleading the tenure. 2. They are free from toll for all things relating to their livelihood and huſbandry; nor can be impannelled on any inqueſt. Theſe tenants held originally by plowing the king's land, plaſhing his hedges, and the like ſervice, for the maintenance of his houſhold; and it was on this account that ſuch liberties were given them, for which they may have writs of *monſtraverunt* to ſuch as take the duties of toll, &c. No lands are to be accounted ancient demeſne, but ſuch as are held in ſocage.

ANCIENTY, in ſome ancient ſtatutes, is uſed for elderſhip or ſeniority. The elder ſiſter can demand no more than her other ſiſters, beſide the chief meſne, by reaſon of her ancienty.

ANCON, in anatomy, implies the gibbous eminence of flexure of the cubit, the middle of the eminence on which we lean, the greateſt of the two apophyſes of the ulna, and the ſame with the olecranon.

ANCONÆUS, in anatomy, names given to certain muſcles.

ANCREE, in heraldry, the ſame as ANCHORED.

ANCUS, in ſurgery, implies a ſtiffneſs in the arm, ſo as to render it conſtantly crooked.

ANCONES, in architecture, the corners or quoins of walls, croſs-beams, or rafters.

ANCONY, in the iron-works, ſignifies a piece of half-wrought iron, of about three quarters of an hundred weight, and of the ſhape of a bar in the middle, but unwrought at the ends.

ANCYLE, in ſurgery, the ſame as ANCYLOSIS.

ANCYLOBLEPHARON, from *αγκυλος*, *bent*, and *βλεφαρον*, *an eye-lid*; a diſeaſe of the eye, which cloſes the eye-lids. This diſorder muſt be diſtinguiſhed from that coalition of the eye-lids which happens from viſcid matter gluing them together. If the coheſion is on the cornea, the ſight is inevitably loſt, which ſometimes happens in the ſmall-pox. If there is only a growing together of the eye-lids, they may be ſeparated with the ſpecillum, and pledgets kept between them to prevent their re-union. If the eye-lids adhere to the eye, they are to be ſeparated by a fine-edged knife; and their re-union is to be prevented by a proper uſe of injections, and lint placed between them, after dipping it in ſome proper liniment.

ANCYLOGLOSSUM, in medical language, implies a contraction of the ligaments of the tongue. Some have this imperfection from their birth, others from ſome diſeaſe. In the firſt caſe, the membrane which ſupports the tongue is too ſhort or too hard: in the latter, an ulcer under the tongue, healing and forming a cicatrix, is ſometimes the cauſe: theſe ſpeak with ſome difficulty. The ancyloglosſi, by nature, are late before they ſpeak; but when they begin, they ſoon ſpeak properly.

ANCYLOMELE, in ſurgical inſtruments, denotes a crooked probe with a hook to it.

ANCYLOSIS, in ſurgery, implies a diſtortion or ſtiffneſs of the joints, cauſed by a ſettlement of the humours, or a diſtenſion of the nerves, and therefore remedies of a mollifying nature are required.

ANCYROIDES, the ſame as CARACOIDES.

ANCYSTRUM, in botany, a genus of the digynia order, belonging to the diandria claſs of plants; the eſſential characters of which are: the calyx is a ſingle-leaved, four-toothed perianthium, four-awn'd, the awns terminated with croſs-barbs: the corolla is four-cleft; the ſtigma pencilled.

ANDA, in botany, a name given to a Brazilian nut-tree, which yields a kind of grey, oily nut, ſomewhat like the cheſnut; but the fruit is only uſed in medicine as a purgative.

ANDABATÆ, in antiquity, a ſort of gladiators, who, mounted on horſeback, or in chariots, fought hoodwinked, having a helmet that covered their eyes.

ANDANTE, or ANDANTI, in muſic, ſignifies a movement moderately ſlow, between *largo* and *allegro*.

ANDECAVI, ANDEGAVI, ANDES, or ANDI, a people of Gallia Celtica, having the Turones to the eaſt, the Namnetes to the weſt, the Pictones to the ſouth, and the Aulerci Cœnomani to the north: now Anjou.

ANDENA, in old writers, denotes the ſwarth made in mowing of hay.

ANDIRA, or ANGELYN, a Brazilian wood of a very hard contexture, and generally uſed by the natives in building. It yields a fruit in a ſhell, the kernel of which is good againſt worms.

ANDIRA, in zoology, ſignifies the large Brazilian bat, commonly called the horned bat.

ANDRACHNE, BASTARD ORPINE, a genus of the gynandria order, belonging to the monœcia claſs of plants; and in the natural method ranking under the 38th order, Tricoccæ. See Syſtem of BOTANY. There are three ſpecies.

1. The telephoides, or herbaceous trailing andrachne, is a low plant, whoſe branches trail upon the ground. The leaves are ſmall, of an oval ſhape, ſmooth, and of a ſea-green colour. It is found wild in Italy and the Archipelago.

2. The fruticoſa, or ſhrubby baſtard orpine, is a native of China, and ſome parts of America.

3. The arborea, with a tree-like ſtalk. This ſpecies grows naturally at Campeachy.

The firſt ſpecies may be raiſed by ſowing the ſeeds in March, on a moderate hot-bed. The other ſpecies are very tender, and therefore muſt be kept conſtantly in the bark-ſtove.

ANDRAPODISMUS, in ancient writers, the ſelling of perſons for ſlaves. Hence Andrapodiſtes, a dealer in ſlaves, and more particularly a kidnapper, who ſteals men or children to ſell them.

ANDRAPODOCAPELI, in antiquity, a kind of dealers in ſlaves. At Athens, ſeveral places in the forum were appointed for the ſale of ſlaves. Upon the firſt day of every month, the merchants, called Ανδραποδοκαπελοι, brought them into the market, and expoſed them to ſale; the crier ſtanding upon a ſtone erected for that purpoſe, called the people together.

ANDREW, *or Knights of St.* ANDREW, an order of knights, more uſually called the order of the thiſtle.

Knights of St. ANDREW, is alſo an order inſtituted by Peter the Great of Muſcovy in 1698; the badge of which is a golden medal; on one ſide whereof is repreſented St. Andrew's croſs, with theſe words, *Cazar Pierre monarque de tout la Ruſſie*. This medal, being faſtened to a blue ribbon, is ſuſpended from the right ſhoulder.

St. ANDREW's *Croſs*, one in form of the letter X, on which the Apoſtle is ſaid to have ſuffered death.

St. ANDREW's *Day*, a feſtival of the Chriſtian church, celebrated on the 30th of November, in honour of the apoſtle St. Andrew.

ANDRIÆ, in Grecian antiquity, public entertainments firſt inſtituted by Minos of Crete, and after his example appointed by Lycurgus at Sparta, at which a whole city or a tribe aſſiſted. They were managed with the utmoſt frugality, and perſons of all ages were admitted; the younger ſort being obliged by the lawgiver to repair thither as ſchools of temperance and ſociety.

ANDRODAS, in claſſical authors, denotes the 63d year of a man's age.

ANDROGYNA, in botany, implies male and female flowers on the ſame root.

ANDROGYNES, in natural hiſtory, ſignifies thoſe living creatures which, by a monſtrous formation of their generative parts, ſeem to unite in themſelves the two ſexes, of male and female. This luſus naturæ, this defect, or perhaps redundancy, in the animal-ſtructure, is deſcribed by medical authors in the following manner. "There is a depravation in the ſtructure of the parts intended by nature for propagation, when, beſides thoſe concealed parts that are found neceſſary for the diſcharge of prolific functions, the pudenda of the other ſex likewiſe appear. This monſtrous production of nature is diverſified in four different ways; of which three appear in males and one in females. In men, the female pudendum, cloathed with hair, ſometimes appears, contiguous to the perinæum; at other times, in the middle of the ſcrotum; at other times, which conſtitutes the third diverſity, through that part itſelf which in the midſt of the ſcrotum exhibits the form of a pudendum, urine is emitted. Near that part which is the teſt of puberty, and above the pudendum, even in females, the maſculine genitals appear in ſome, conſpicuous in all their three forms, one reſembling the viretram, the other like the two veſticles; but for the moſt part it happens, that, of the two inſtruments of generation, one is feeble and inert; and it is extremely rare that both are found ſufficiently valid and proper for feats of love; nay, even in a great many, both theſe members are deficient and impotent, ſo that they can perform the office neither of a male nor of a female."

Since this monſtrous exhibition of nature is not ſuch as to abrogate the rights or deſtroy the character of humanity amongſt human beings, this involuntary misfortune implies no right to deprive thoſe upon whom it is inflicted by nature, of the privileges natural to every citizen.

ANDROGYNOUS, in zoology, an appellation given to animals which have both the male and female ſex in the ſame individual. In botany, the term is applied to ſuch plants as bear both male and female flowers on the ſame root.

ANDROGYNUM, in eccleſiaſtical law, denotes the ſtate of matrimony.

ANDROIDES, in mechanics, implies a human figure, which, by certain ſprings or other movements, is capable of performing ſome of the natural motions of a living man.

A very remarkable figure of this kind appeared in Paris, in the year 1738. It repreſented a flute-player, and was capable of performing many different pieces of muſic on the german flute; which, conſidering the difficulty of blowing that inſtrument, the different contractions of the lips neceſſary to produce the diſtinctions between the high and low notes, and the complicated notions of the fingers, muſt appear truly wonderful.

This machine was the invention of M. Vaucanſon, member of the Royal Academy of Sciences; and a particular deſcription of it was publiſhed in the Memoirs of the Academy for that year.

The conſtruction of machines capable of imitating even the mechanical actions of the human body, ſhow exquiſite ſkill; but what ſhall we ſay of one capable, not only of imitating actions of this kind, but of acting as external circumſtances require, as though it were endowed with life and reaſon? This, neverthelefs, has been done. For M. de Kempelen, a gentleman of Preſburg in Hungary, excited by the performances of M. de Vaucanſon, at firſt endeavoured to imitate them, and at laſt far excelled them. This gentleman conſtructed an Androides capable of playing at cheſs!

Every one who is acquainted with this game muſt know, that it is ſo far from being mechanically performed, as to require a greater exertion of the judgment and rational faculties than is ſufficient to accompliſh many matters of greater importance. That this machine was really made, the public have had ocular demonſtration. The inventor came over to Britain in 1783, where he remained above a year with his automaton.

Mr. de Kempelen remarks as the moſt ſurpriſing circumſtance attending his automaton, that it had been exhibited at Preſburg, Vienna, Paris, and London, to thouſands, many of whom were mathematicians and cheſs-players, and yet the ſecret by which he governed the motion of its arm was never diſcovered.

ANDROLEPSY, in Grecian antiquity, an action allowed by Athenians againſt ſuch as protected perſons guilty of murder. The relations of the deceaſed were empowered to ſieze three men in the city or houſe whither the malefactor had fled, till he was either ſurrendered, or ſatisfaction made for the murder.

ANDROMACHE, in mythology, the wife of Hector, the mother of Aſtyanax, and daughter of Eton king of Thebes in Cilicia. After the death of Hector and the deſtruction of Troy, ſhe married Pyrrhus; and afterwards Helenus the ſon of Priam, with whom ſhe reigned over part of Epirus.

ANDROMACHE, in pharmacy, denotes Venice terpentine.

ANDROMEDA, in aſtronomy, a northern conſtellation, behind Pegaſus, Caſſiopeia, and Perſeus. It repreſents the figure of a woman chained; and is fabled to have been formed in memory of Andromeda, daughter of Cepheus and Caſſiopeia, and wife of Perſeus, by whom ſhe had been delivered from a ſea-monſter, to which ſhe had been expoſed to be devoured for her mother's pride.

Andromeda, or Marſh Cyſtus: A genus of the monogynia order, belonging to the decandria claſs of plants; and in the natural method ranking under the 18th order, Bicornes. For the characters ſee Syſtem of Botany.

There are five ſpecies. 1. The polifolia is a low plant, growing naturally in bogs in the northern countries. 2. The mariana, a native of North America. 3. The paniculata a native of Virginia and Carolina, growing in moiſt places. 4. The arborea is a native of the ſame countries, where it is called the ſorrel tree. 5. The calyculata, is a native of Siberia, and likewiſe of North America. All theſe ſorts, are hardy plants.

ANDRON, in Grecian antiquity, denotes the apartment in houſes deſigned for the uſe of men; in which ſenſe it ſtands oppoſed to Gynæceum.

The Greeks alſo gave their dining-rooms the title of andron becauſe the women had no admittance to feaſts with the men.

ANDRONA, in antiquity, denoted a ſtreet, or public place, where people met and converſed together. In ſome writers, androna ſignifies the ſpace between two houſes; in which ſenſe, the Greeks uſe the term ανδρωνας, for the way or paſſage between two apartments.

Androna, in eccleſiaſtical writers, ſignifies that part in churches deſtined for the men. Anciently it was the cuſtom for the men and women to have ſeparate apartments in places of worſhip, where they performed their devotions aſunder; which method is ſtill religiouſly obſerved in the Greek church. The ανδρων, or androna, was in the ſouth ſide of the church, and the womens apartment on the north.

ANDRONION, in medicine, ſignifies the paſtil of the celebrated phyſician Andro, and ſaid to be good againſt carbuncles on the face.

ANDROPHAGI, in ancient geography, the name of a nation whoſe country was adjacent to Scythia. Their name is compounded of two Greek words, and ſignifies man-eaters.

ANDROPOGON, or Man's-beard, in botany, a genus of the monœcia order, belonging to the polygamia claſs; and in the natural method ranking under the 4th order, graminæ. The hermaphrodite calyx is a one-flowered bivalved glume: the corolla is a bivalved glume awned at the baſe: the ſtamina conſiſt of three capillary filaments; the antheræ are oblong and bifurcated: the piſtillum has an oval germen; with two capillary ſtyli coaleſced, and villous ſtigmata: there is no pericarpium, the ſeed is one, ſolitary, and covered. The male calyx, corolla, and ſtamina, the ſame with the hermaphrodite; but the corolla without the awn.

There are above 18 ſpecies. Of theſe the moſt remarkable is the nardus, which produces the Indian nard or ſpikenard of the ſhops.

The ſpikenard, as brought from the Eaſt Indies, is a congeries of ſmall fibres iſſuing from one head, and matted cloſe together, ſo as to form a bunch about the ſize of the finger, with ſome ſmall ſtrings at the oppoſite end of the head. Spikenard has a warm, pungent, bitteriſh taſte; and a ſtrong not very agreeable ſmell.

It is ſtomachic and carminative; and ſaid to be alexipharmac, diuretic, and emmenagogue.

ANDROSÆMUM, Tutsan, or Hyperecum, in botany, implies a ſynonyme of the herb St. John's wort.

ANDROSACE, a genus of the monogynia order, belonging to the pedandria claſs of plants; and in the natural method ranking under the 21ſt order, Preciæ. For the characters ſee Syſtem of Botany. Of this genus there are ſix ſpecies. 1. The maxima grows naturally in Auſtria and Bohémia, among the corn. It has broad leaves, which ſpread near the ground; from the centre of theſe the footſtalks ariſe, which are terminated by an umbel of white flowers like thoſe of the auricular. 2. The ſeptentrionalis, villoſa, carnea, and lactea, grow naturally on the Alps and Helvetian mountains. Of the other ſpecies, called the elongata, we have no particular deſcription.

Theſe plants are propagated by ſeeds, which ſhould be ſown ſoon after they are ripe, otherwiſe they ſeldom come up the ſame year.

ANDRUM, a kind of hydrocele, to which the people of Malabar, are very ſubject. Its origin is derived from the vitious quality of the country waters, impregnated with corroſive muriatic ſalts, the ſource of moſt other diſeaſes that infect the Malabarians. Its ſymptoms, are an erryſipelas of the ſcrotum, returning every new moon, by which the lymphatics, being eroded, pour a ſerous ſaline humour into the cavity of the ſcrotum. The andrum is incurable; for thoſe once ſeized with it have it for life.

ANDRYALA, Downy Sow-Thistle: a genus of the polygamia æqualis order, belonging to the ſyngeneſia claſs of plants: and in the natural method ranking under the 49th order, Compoſitæ-ſemifloſculus. The eſſential characters are: the receptacle is villous; the calyx is many parted, ſubequal, and rounded; and the pappus is ſimple and ſeſſile.

There are four ſpecies. 1. The integrifolia is an annual plant, growing naturally in the ſouth of France, Spain, and Italy. It riſes to the height of a foot and an half, with woolly branching ſtalks. 2. The raguſina is a native of the Cape of Good Hope. 3. The lanata is a native of Sicily and of the country round Montpelier. 4. The ſinuata grows in Spain and Portugal: the leaves are broader, longer, and more downy, than either of the other ſorts; the flower-ſtalks ariſing more than a foot high. All theſe plants are eaſily propagated by ſeeds, which ſhould be ſown in autumn.

ANECDOTE, Anecdota, in literature, ſignifies the titles of ſecret hiſtories; but it properly denotes a relation of detached and intereſting particulars. The word is Greek, ανεκδοτα, q. d. things not yet known or hitherto kept ſecret.

Anecdotes, in literary hiſtory, implies an appellation given to ſuch works of the ancients as have not yet been publiſhed.

ANEE, in commerce, ſignifies a meaſure for grain, uſed in ſome provinces of France. At Lyons, it ſignifies 80 Engliſh quarts, wine-meaſure.

ANELE, or Anil, implies the ſame with Indico.

ANEMIUS Furnus, among chemiſts, denotes a wind furnace, which draws the air ſo as to perform the operation of fuſion without the aſſiſtance of a bellows.

ANEMOMETER, in mechanics, implies a machine for meaſuring the force and velocity of the wind.

ANEMONE, Wind-flower, a genus of the polygnia order, belonging to the polyandria claſs of plants; and in the natural method, ranking under the 26th order, Multiſilique. It has its name from the Greek ανεμος, ſignifying the wind; becauſe the flower is ſuppoſed not to open unleſs the wind blows. For its characters ſee Syſtem of Botany.

Linnæus enumerates 21 ſpecies; of this genus 1. The nemoroſa, which grows wild in the woods in many parts of Britain, where it flowers in April and May. The flowers are white or high purple, ſingle; or reddiſh brown, double. 2. The appennina is likewiſe a native of Britain, growing in woods. 3. The coronaria. 4. The hortenſis. Theſe two are natives of the Levant, particularly of the Archipelago iſlands, where the borders of the fields are covered with them of the moſt beautiful colours.

The firſt and ſecond may be propagated by taking up their roots when the leaves decay, and tranſplanting them in wilderneſſes, where they will thrive and increaſe greatly, if they are not diſturbed. The two laſt ſorts require a good deal of care.

Sea Anemone, the ſame as Animal-Flower.

ANEMOSCOPE, a machine that ſhows either the courſe or velocity of the wind.

The machine which ſhows the courſe of the wind, conſiſts of an index moving about an upright circular plate, like the dial of a clock, on which the 32 points of the compaſs are drawn inſtead of the hours. The index, which points to the diviſions on the dial, is turned by a horizontal axis, having a trundle-head at its external extremity. This trundle-head is moved by a cog-wheel on a perpendicular axis; on the top of which a vane is fixed, that moves with the courſe of the wind, and puts the whole machine in motion. The whole contrivance is extremely ſimple; and nothing required in the conſtruction, but that the number of cogs in the wheel, and rounds in the trundle-head, be equal; becauſe it is neceſſary, that, when the vane moves entirely round, the index of the dial alſo makes a complete revolution.

The anemoſcope, calculated for indicating the force or velocity of the wind, is the ſame with what moſt writers call an anemometer: and we have accordingly deſcribed one of thoſe machines under that article.

ANEMOSPERMOS, in botany, a ſynonyme of Arctotis.

ANETHUM, Dill and Fennel, a genus of the digynia order, belonging to the pentandria claſs of plants; and, in the natural method, ranking under the 45th order, Umbellatæ. For the characters, ſee Syſtem of Botany.

There are two ſpecies. 1. The graveolens, or dill, is an annual plant: the root is long, ſlender, and white: the leaves are divided into a multitude of fine, long, narrow ſegments like thoſe of fennel, but of a blueiſh green colour, and leſs ſtrong ſmell. The ſtalk is round and firm, growing to the height of four feet, with yellow flowers in large umbels.

2. The feniculum, or fennel; of which there are two varieties, the common and the ſweet. The ſweet fennel is ſmaller in all its parts than the common, except the ſeeds, which are conſiderably larger. Both ſorts are cultivated in gardens: the common is a perennial plant: the ſweet fennel periſhes after it has given ſeed.

Of the firſt ſpecies, only the ſeeds are uſed in medical preparations. Both the ſeeds and roots of fennel are uſed in medicine. They are ranked among the four greater hot ſeeds, and not undeſervedly looked upon as good ſtomachics and carminatives.

ANEURISM, or Aneurysm, in ſurgery, a throbbing tumor, diſtended with blood, and formed by a dilation or rupture of an artery.

ANFEALTHILE, or Anfeldthyde, in law, implies a ſimple accuſation, contradiſtinguiſhed from a complex one; which, in the Saxon code, anſwered to thoſe in the Engliſh ſtatutes, that hold to bail, being ſimple, and thoſe that can take no bail, as complex.

ANGARI, or Angarii, in antiquity, denote public couriers, appointed for carrying meſſages.

The ancient Perſians, Budæus obſerves, had their αγγαρειον δρομημα; which was a ſet of couriers on horſeback, poſted at certain ſtages or diſtances, always in readineſs to receive the diſpatches from one, and forward them to another, with wonderful celerity, anſwering to what the moderns call poſts, as being poſted at certain places or ſtages.

ANGARIA, in Roman antiquity, a kind of public ſervice impoſed on the provincials, to provide horſes and carriages for the conveyance of military ſtores, and other public burdens.

ANGEIOTOMY, in ſurgery, implies the opening a vein or artery, as in bleeding; and conſequently includes both arteriotomy and phlebotomy.

ANGEL, a ſpiritual intelligent ſubſtance, the firſt in rank and dignity among created beings. The word Angel is Greek, and ſignifies a meſſenger: the Hebrew הלאר ſignifies the ſame thing. The angels are in Daniel (chap. iv. ver. 13, &c.) called שם, or watchers, from their vigilance: for the ſame reaſon they are, in the remains we have of the prophecy attributed to Enoch, named Egregori; which word imports the ſame in Greek.

Angels, therefore, in the proper ſignification of the word, do not import the nature of any being, but only the office, to which they are appointed, eſpecially by way of meſſage, or intercourſe between God and man: in which ſenſe they are called the miniſters of God, who do his pleaſure, and miniſtring ſpirits ſent forth to miniſter for them who ſhall be heirs of ſalvation.

That there are ſuch beings as we call angels, that is, certain permanent ſubſtances, inviſible, and imperceptible to our ſenſes, endued with underſtanding and power ſuperior to that of human nature, created by God, and ſubject to him as the ſupreme Being; miniſtring to his divine providence in the government of the world by his appointment, and more eſpecially attending the affairs of mankind; is a truth ſo fully atteſted by Scripture, that it cannot be doubted.

The creation of angels is not expreſsly mentioned by Moſes in the firſt of Geneſis, yet it is generally conſidered by judicious expoſitors as implied. All the writers that we have ſeen on this ſubject, think they were included in the firſt day's work, when the heavens were framed.

On a ſubject of this nature, it would be imprudent to indulge a ſpirit of conjecture: ſcripture is the only ſtandard by which truth and error can be tried, and to this we muſt ultimately appeal.

It is acknowledged that Moſes has not expreſsly mentioned angles by name; yet, as we have remarked, their creation is undoubtedly implied: for the heavens muſt include all that are in them; and therefore it is that the divine penman ſays, in the concluſion of his narrative, "Thus the heavens and the earth were finiſhed, and all the hoſt of them."

As the numbers of Angels are very great, it may well be ſuppoſed that there ſeveral orders in their government; the ancient fathers of the Chriſtian church have divided them into three Hierarchies, and theſe are divided again into three claſſes; viz.

1ſt Hierarchy.	2d Hierarchy.	3dHierarchy.
Seraphim	Virtues	Principalities
Cherubim	Powers	Archangels
Thrones	Dominations	Angels.

The Seraphim are, of all other ſpirits, the moſt inflamed with holy love. The Cherubim are the moſt enlightened, and communicate their rays and ſcience to the other orders. The Thrones are thoſe that encircle the majeſty of God. The Virtues are mighty to work wonder and miracles. The Powers counteract and prevent the malevolence of evil demons. The Dominations have the government of man. The Principalities have the charge of ſtates and kingdoms. Archangels are commiſſioned only on extraordinary occaſions; and Angels are the common heralds and meſſengers of Heaven.

Whatever grounds there may be for this particular arrangement of ſpiritual beings into ſo many different claſſes, allotting to each their peculiar departments, it is not our preſent purpoſe to enquire; but certain it is that there are ſuch beings; for no age or nation, whatever their tenets might be, but allowed of their exiſtence.

The Jews reckon four orders or companies of Angels, each headed by an Arch-angel; the firſt order being that of Michael, the ſecond of Gabriel, the third of Uriel, and the fourth of Raphael: but though the Jews believe them to be four, yet it ſeems there were rather ſeven.

Although the Angels were originally created perfect, good, and obedient, to their Maſter's will, yet ſome of them ſinned, and kept not their firſt eſtate, but left their habitation; and ſo, of the moſt bleſſed and glorious, became the moſt vile and miſerable of all God's creatures.

They were expelled the regions of light, and caſt down to hell, to be reſerved in everlaſting chains, under darkneſs, until the day of judgment. With heaven they loſt their heavenly diſpoſition, which delighted once in doing good and praiſing God; and fell into a ſettled rancour againſt him, and malice againſt men: their inward peace was gone; all deſire of doing good departed from them; and, inſtead thereof, revengeful thoughts and deſpair took poſſeſſion of them, and created an eternal hell within them.

What offence they committed, or at what period theſe apoſtate ſpirits fell from heaven, and plunged themſelves into ſuch an abyſs of wickedneſs and woe, are queſtions impoſſible to be determined by any evidence of Scripture. But on what occaſion ſoever it firſt ſhowed itſelf, pride ſeems to have been the leading ſin of the angels; who, admiring and valuing themſelves too much on the excellence of their nature, and the height of their ſtation, came at length to entertain ſo little reſpect for their Creator, as to be guilty of downright rebellion and apoſtacy.

It is certain from Scripture, that theſe fallen angels were in great numbers, and that there were alſo ſome order and ſubordination preſerved among them; one eſpecially being conſidered as their prince, and called by ſeveral names, Beelzebub, Satan, or Sammaël by the Jews; Ahârimam, by the Perſians; and Eblis, by the Mahometans. Their employment is not only evil themſelves, but endeavouring, by all arts and means, to ſeduce and pervert mankind, by tempting them to all kind of ſin, and thereby bringing them into the ſame deſperate ſtate with themſelves.

ANGEL, in commerce, the name of a gold coin formerly current in England, and valued at ten ſhillings. It had its name from the figure of an angel repreſented upon it, weighed four pennyweights, and was twenty-three and a half carats fine.

ANGEL FISH, in ichthyology, a ſpecies of ſqualus.

ANGELIC, or ANGELICAL, ſomething belonging to, or that partakes of, the nature of Angels. We ſay, an angelical life, &c. St. Thomas is ſtiled the angelical doctor. The angelical ſalutation is called by the Romaniſts Ave Maria; ſometimes ſimply Angelus.

ANGELIC GARMENT, *Angelica Veſtis*, among our anceſtors, was a monkiſh garment, which laymen put on a little before their death, that they might have the benefit of the prayers of the monks.

ANGELICA, a genus of the digynia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 45th order, Umbellatæ. The eſſential characters are, the fruit is roundiſh, angled, ſolid, with reflected ſtyli; the corollæ are equal, and the petals incurvated. There are five ſpecies.

1. The ſativa, or common angelica, which is cultivated in gardens for medicinal uſe, and likewiſe for a ſweetmeat, grows naturally in the northern countries. The root is brown, oblong, and an inch or two thick, fragrant, and acrid. The leaves are very large, compoſed of pinnated foliola, of an oblong oval figure, dentated at the edge, and the odd leaf at the end of the pinna lobated; the ſtalk is round, ſtriated, and as thick as a child's arm.

2. The arch-angelica is a native of Hungary and Germany.

3. The ſylveſtris grows naturally in moiſt meadows, and by the ſides of rivers, in many parts of Britain.

4. The atro-purpurea canadenſis; 5. The lucida canadenſis. Theſe are natives of North America, but have neither beauty nor uſe.

The common angelica delights to grow in a moiſt ſoil: the ſeeds ſhould be ſown ſoon after they are ripe.

For the purpoſes of medicine, Bohemia and Spain produce the beſt kinds of angelica. The London college direct the roots brought from Spain to be alone made uſe of.

All the parts of angelica, eſpecially the root, have a fragrant aromatic ſmell, and a pleaſant bitteriſh warm taſte, glowing upon the lips and palate for a long time after they have been chewed.

Angelica is one of the moſt elegant aromatics of European growth, though little regarded in the preſent practice. The root, which is the moſt efficacious part, is uſed in the aromatic tincture; and the ſtalks make an agreeable ſweat-meat.

ANGELICS, in Grecian antiquity, a celebrated dance performed at their feaſts; ſo called, becauſe the Dancus were dreſſed in the habit of meſſengers.

ANGELICS, the name of an order of knights, inſtituted in 1191, by Angelus Flavius Commenus, emperor of Conſtantinople.

ANGELICS alſo ſignifies a congregation of nuns, founded at Milan in 1534, by Louiſa Torelli, counteſs of Guaſtalla. They obſerve the rule of St. Auguſtine.

ANGELINA, ZANONI ACOSTÆ, in botany, is a tree which grows to a monſtrous ſize in the Eaſt Indies; ſome ſay to 16 feet thick, and bears fruit for a whole century without ceaſing. The leaves contain many medicinal virtues.

ANGELOT, an ancient Engliſh gold coin, ſtruck at Paris, while under ſubjection to the Engliſh. It was thus called from the figure of an angel ſupporting the eſcutcheon of the arms of England and France.

ANGELOT alſo denotes a ſmall fat, rich ſort of cheeſe, brought from Normandy.

ANGER, a violent paſſion of the mind, conſiſting in a propenſity to take vengeance on the author of ſome real or ſuppoſed injury done to the offended party.

Anger is either deliberative or inſtinctive; and the latter kind is raſh and ungovernable, becauſe it operates blindly, without affording time for deliberation.

All anger is not ſinful: hence the precept, "Be ye angry and ſin not." It becomes ſinful, however, and contradicts the rule of Scripture, when it is conceived upon ſlight and inadequate provocations, and when it continues long. It is then contrary to the amiable ſpirit of charity, which "ſuffereth long, and is not eaſily provoked."

"provoked." Hence theſe other precepts, "Let every man be ſlow to anger;" and, "Let not the ſun go down upon your wrath."

Theſe precepts, and all reaſoning upon the ſubject, ſuppoſe the paſſion of anger to be within our power: and this power conſiſts not ſo much in any faculty we have of appeaſing our wrath at the time, as in mollifying our minds by habits of juſt reflection, ſo as to be leſs irritated by impreſſions of injury, and therefore ſooner pacified.

ANGERIOGRAPHY, or Angeliology, among anatomiſts, implies a deſcription and hiſtory of the ſeveral veſſels of the human body.

ANGERONA, or Angina, in mythology, a pagan deity to whom the Romans prayed for the cure of the quinzy. She is repreſented with her mouth covered, to denote patience and refraining from complaints.

Her ſtatue was ſet up, in the temple of the goddeſs Volupia, to ſhow that a patient enduring of affliction, leads to pleaſure.

ANGERONALIA, in Roman antiquity, were ſolemn feaſts held by the Romans the 21ſt of December, in honour of Angerona.

ANGEROTOMY, in ſurgery, implies the opening of any of the veſſels of the human body.

ANGINA, in medicine, a violent inflammation of the throat, uſually called quinzy.

ANGIOSPERMIA, in botany, the ſecond order in the claſs didynamia. It conſiſts of thoſe plants, of that claſs, whoſe ſeeds are incloſed in a pericarpium. In this order the ſtigma is generally obtuſe.

ANGLE, the inclination of two lines meeting one another in a point.

Angle *of the Sun's Poſition*, is formed by the meridian and azimuth, or other great circle drawn through the center of the ſun.

Angle *of the Longitude*, is formed at the pole of the ecliptic, between the meridian, and a circle of longitude drawn through the center of the object.

Angle *at the Center*, in fortification, denotes, that which is found in the center of the figure by lines drawn from the angles of the figure.

Angle *of a Baſtion*, is that which the two faces of it form at the point of the baſtion.

Angle *of Incidence*, in optics, the angle which a ray of light makes with a perpendicular to that point of the ſurface of any medium on which it falls; though it is commonly underſtood of the angle which it makes with the ſurface itſelf; however, the former is the true explanation.

Angle *of Refraction*, generally implies the angle which a ray of light, refracted by any medium, makes with a perpendicular to that point of the ſurface on which it was incident; but it is ſometimes underſtood to be the angle which it makes with the ſurface of the refracting medium itſelf.

Angle *of the Terraille*, is formed by the line of defence, and the flank of the baſtion.

Angle *of Circumference*, is formed by an arch drawn from one gorge to the other.

Diminiſhed Angle, is formed by a line drawn from the face of the baſtion to the exterior ſide of the polygon.

Flanking Angle, is formed by the line of defence, and the flank of the baſtion.

Angle *Saliant*, points outwards towards the field.

Angle *of the Polygon*, is formed by two ſides of the polygon.

Angle *of the Complement of the Line of Defence*, is formed by the interſection of two complements with each other.

Angle *of the Moat*, is formed before the curtain where it is interſected.

Angle *of a Battalion*, in military affairs, is the laſt man where the rank and file terminates.

ANGLER, implies a perſon who practiſes the art of angling.

Angler, in ichthiology, the Engliſh name of a ſpecies of lophus.

ANGLES, in hiſtory, an antient German nation, originally a branch of the Suevi; who, after various migrations, ſettled in that part of Denmark, and duchy of Sleſwick, which to this day is called Angel, and of which the city of Flenſburgh is the capital. They were known, in the time of Tacitus, by the name of Angli.

To this nation the Britiſh ambaſſadors applied when ſoliciting ſuccours againſt the Scots and Picts. Who came over in greater numbers than any other Saxon nation; and accordingly had the honour of giving the name of Anglia to England.

ANGLING, in a general ſenſe, denotes the art of fiſhing with a rod, to which are fitted a line, hook and bait.

In angling the following rules are to be obſerved; 1. To place yourſelf ſo that your ſhadow do not at any time lie upon the water if ſhallow. 2. To angle in a pond near where the cattle go to drink, and in rivers in ſuch places as the fiſh you intend to angle for uſually frequent.

The beſt times for angling are from April to October, for in cold ſtormy weather fiſh will not bite. The morning is always the beſt time; however the afternoon of a cloudy day is generally good.

The beſt way to angle with a fly is down the river, with well timed baits and a proper ſized hook.

ANGLO Calvinists, a name given by ſome writers to the members of the church of England, as agreeing in many points with the calviniſts of other countries.

ANGLO Saxon, an appellation given to the language ſpoken by the Engliſh Saxons, in contradiſtinction to both the true Saxon and the modern Engliſh.

ANGON, in ancient hiſtory, denotes a kind of javelin, uſed in Gaul in the ſhape of the fleur de lys at the point.

ANGONÆUS, or Anconæus, in anatomy, the muſcle of the arm inſerted in the ſhoulder or ancon.

ANGUILLA, in zoology, the ſame with the eel.

ANGUILLIFORM, an appellation given by zoologiſts to all eel ſhaped animals.

ANGUINA, the ſame as Tricosanthes.

ANGUINUM Ovum, a fabulous kind of egg, ſaid to be produced by the ſaliva of a cluſter of ſerpents, and poſſeſſed of magical virtues.

This ſuperſtition was prevalent among the ancient Britons, and there ſtill remains a tradition of it in Wales. Pliny has given an account of it, and of which the following may ſerve as a tranſlation:

> But tell me yet
> From the grot of charms and ſpells,
> Where our matron ſiſter dwells,
> Brennus, has thy holy hand
> Safely brought the Druid wand,
> And the potent Adder-ſtone,
> Gender'd 'fore the autumnal moon?
> When, in undulating twine,
> The foaming ſnakes prolific join;
> When they hiſs, and when they bear
> Their wond'rous egg aloof in air:
> Thence before to earth it fall,
> The Druid in his hallow'd pall,
> Receives the prize,
> And inſtant flies,
> Follow'd by the envenom'd brood,
> 'Till he croſs the cryſtal flood.

This wondrous egg ſeems to have been nothing more than a large bead of glaſs, uſed by the Druids as a charm to impoſe on the vulgar, whom they made believe, that the poſſeſſor would be fortunate in all his undertakings.

ANGUIS, or Snake, in zoology, a genus belonging to the order of amphibia ſerpentes. For character, ſee Syſtem of Botany. There are 15 ſpecies, viz.

1. The eryx, a native of Britain and likewiſe of America; about a ſpan in length, and about the thickneſs of a man's finger. The tongue broad and forked, the noſtril ſmall and high in the noſe, the eyes lodged in oblong fiſſures above the angle of the mouth; belly of a bluiſh lead colour, marked with ſmall white ſpots irregularly diſpoſed: the reſt of the body of a greyiſh brown, with three longitudinal duſky lines; one extending from the head along the back to the point of the tail; the others broader, and extending the whole length of the ſides. And covered over with ſmall ſcales.

2. The fragilis, blindworm, or ſlow-worm, which is common in Great Britain, and grows to about a foot in length, and to the thickneſs of a man's little finger: the irides are red; the head ſmall; the neck ſtill more ſlender; from that part the body grows ſuddenly, and continues of an equal bulk to the tail, which ends quite blunt. The colour of the back is cinerous, marked with very ſmall lines compoſed of minute black ſpecks: the ſides are of a reddiſh caſt; the belly duſky; both marked like the back. The tongue is broad and forked; the teeth are minute and numerous, and the ſcales ſmall. The motion of this ſerpent is ſlow, from which, it derived its name. It reſembles the viper in the manner of producing its young.

3. The ventralis, or glaſs-ſnake, has 127 ſquamæ on the belly, and 223 on the tail. The head is very ſmall, and the tongue of a ſingular form. The upper part of the body is brown and green, blended together and regularly ſpotted with yellow. The ſkin is very ſmooth; and ſhining with ſmall ſcales, cloſely connected, and of a different ſtructure from thoſe of other ſerpents. They appear earlier in the ſpring than any other ſerpent, and are numerous in the ſandy woods of Virginia and Carolina, where they are ſaid to be harmleſs.

4. The jaculus, or dart-ſnake, is about ten or twelve inches long, and of the thickneſs of a man's little finger. Its colour is a milky grey on the back, variegated with ſmall black ſpots like ſo many eyes; and on the belly it is perfectly white. The neck is wholly black; and from that two milk-white ſtreaks run all the way along the back to the tail: the black ſpots are each ſurrounded with a ſmall circle of white. It has its name from its vibrating its body in the manner of a dart. It is a native of Egypt, Libya, and the iſlands of the Mediterranean.

5. The quadrupes: The body of this ſpecies is cylindrical, with 14 or 15 longitudinal aſh-coloured ſtreaks; the teeth are extremely ſmall; it has no ears: the feet are at a great diſtance from each other, very ſhort, with five toes and ſmall nails; but the

toes are ſo minute, that they can hardly be numbered: it is a native of Java.'

6. The bipes, is a native of the Indies; it has two ſhort feet, with two toes, near the anus. In every ſcale of the bipes there is a brown point.

7. The meleagris, is likewiſe a native of the Indies; it has ſmall teeth, but no ears. This ſpecies has a great reſemblance to the former.

8 The colubrina, an inhabitant of Egypt, is beautifully variegated with pale and yellow colours.

9. The maculata, a native of America, is yellow and interſperſed with aſh-couloured lines on the back: the head is ſmall in proportion to the body.

10. The reticulata, a native of America, has browniſh ſcales, with a white margin.

11. The ceraſtes, with 200 ſquamæ on the belly and 15 on the tail, is a native of Egypt.

12. The lumbricalis, a native of America, has 230 ſquamæ on the belly and ſeven on the tail; its colour is a yellowiſh white.

13. The platura: The head is oblong and without teeth; the body is about a foot and a half long, black above and white below; the tail is about one-ninth of the length of the animal, much compreſſed or flatted, and variegated with black and white; the ſcales are roundiſh, ſmall, not imbricated and are exceedingly numerous.

14. The laticauda, a native of Surinam: the tail is compreſſed, acute, pale, with browniſh belts.

15. The ſcytale, a native of the Indies, with 220 ſquamæ on the belly and 13 on the tail. The head is ſmall and oval, and the eyes are little; the body is cylindrical, about a foot and a half long, covered with oval obtuſe ſcales: the tail is thick and obtuſe like the head; it colour is white, interſperſed with browniſh rings; the margins of the ſcales are of an iron colour; and the top of the head blue. Linnæus informs us, that none of this genus are poiſonous.

ANGULAR, in a general ſenſe, denotes ſomething that relates to or hath angles. In aſtronomy, angular motion ſignifies the increaſe of the diſtance between any two planets revolving round any body as the common center of their motion.

ANGUNEAL Hyperbola, a kind of ſerpentizing hyperbola, cutting its aſymptotes with centre flexions.

ANGURIA, the Water-Melon, a genus of the diandria order, belonging to the monœcia claſs of plants: and in the natural method ranking under the 34th order, Cucurbitaceæ. For the characters ſee Syſtem of Botany.

Of this genus, Linnæus reckons three ſpecies, the trilobata, pedata, and trifoliata; but only one is known in this country, by the name of Citrul. The fruit is cultivated in Spain, Portugal, Italy, and other warm countries of Europe; as alſo in Africa, Aſia, and America; where it is eſteemed on account of its wholeſome cooling quality; but in this country it is held in little eſtimation.

ANGUSTICLAVIA, in Roman antiquity, a tunica embroidered with little purple ſtuds. It was worn by the Roman knights, as the laticlavia was by the ſenators.

ANHELATIO, or Anhelitas, among phyſicians, implies a ſhortneſs of breath.

ANHIMA, in ornithology, ſignifies a ſpecies of the cane, found in Brazil, South America.

ANHINGA, in ornithology, ſignifies a ſpecies of the duck, found in Brazil, South America.

ANHLOTE, or Anscot, in law, ſignifies a ſingle tribute of tax, uſually called Scot and Lot.

ANHUIBA, the ſame as Saſſafras.

ANHYDROS, in botany, a ſynonyme for the ſtrychna, or nightſhade, a poiſonous plant.

ANI, in ornithology, ſignifies the Brazilian paroquet.

ANIL, in botany, a ſynonyme of a ſpecies of indigofera.

ANIMA, among divines and naturaliſts, denotes the ſoul, or principle of life, in animals.

Anima, among chemiſts, denotes the volatile or ſpirituous parts of bodies.

Anima *Hepatis*, is a name by which ſome call ſal martis, or ſalt of iron, on account of its ſuppoſed efficacy in diſeaſes of the liver.

Anima *Mundi*, in metaphyſics, implies a certain pure ethereal ſubſtance or ſpirit, diffuſed, according to many of the ancient philoſophers, through the maſs of the world, informing, actuating, and uniting the divers parts thereof into one great, perfect, organical, and vital body or animal.

Anima *Saturni*, a white powder obtained by pouring diſtilled vinegar on litharge, and is of conſiderable uſe in enamelling.

ANIMADVERSION, in literature, ſignifies a particular ſcrutiny of any ſubject, in order to point out its errors or defects in the moſt ſcrupulous manner.

ANIMAL, in natural hiſtory, implies an organized and living body, endowed with ſenſation; thus, minerals are ſaid to grow or increaſe, plants to grow and live, but animals alone to have ſenſation.

Animal, uſed adjectively, denotes any thing belonging to, or partaking of, the nature of animals. Thus we ſay animal actions, which imply thoſe that are peculiar to animals; ſuch are ſenſation and muſcular motion.

Animal *Flower*, in zoology, a name given to ſeveral ſpecies of animals belonging to the genus of Actinia of Linnæus. They have likewiſe been diſtinguiſhed by the names of Urtica Marina, or Sea-nettle, from their ſuppoſed property of ſtinging; and Sea-anemone, from their claws or tentacles being diſpoſed in regular circles, and tinged with a variety of bright lively colours, reſembling the petals of ſome of our moſt beautiful flowers. As to one ſpecies particularly, mentioned by Abbé Diequemarre, Phil. Tranſ. for 1773, art. 37. the pureſt white, carmine, and ultramarine, are ſaid to be ſcarce ſufficient to expreſs their brilliancy. The bodies of ſome of them are hemiſpherical, of others cylindrical, and of others ſhaped like a fig. Their ſubſtance likewiſe differs; ſome are ſtiff and gelatinous, others fleſhy and muſcular; but all of them are capable of altering their figure when they extend their bodies and claws in ſearch of food. They are found on the rocky coaſts of the Weſt India iſlands, and likewiſe on ſome parts of the coaſt of England.

They have only one opening or mouth, which is in the centre of the uppermoſt part of the animal: round this are placed rows of fleſhy claws; this opening or mouth is capable of great extenſion. Theſe animals, though exceedingly voracious, will bear long faſting. They may be preſerved alive a year, or longer, in a veſſel of ſea-water, without any viſible food; but, when food is preſented, one of them will ſucceſſively devour two muſcles in their ſhells, or even ſwallow a whole crab as large as a hen's egg. In a day or two the crab-ſhell is voided at the mouth, perfectly cleared of all the meat. The muſcle-ſhells are likewiſe diſcharged whole, with the two ſhells joined together, but entirely empty, yet there is not the leaſt particle of fiſh to be perceived on opening them. An anemone of one ſpecies will even ſwallow an individual of another ſpecies; but, after retaining it ten or twelve hours, will throw it up alive and uninjured.

Through this opening it produces its young alive, furniſhed with claws, which, as ſoon as they fix themſelves, they begin to extend in ſearch of food.

A particular ſpecies of animal-flowers has been found in ſome of the iſlands ceded to Britain at the laſt treaty of peace with France; and the following account of them was publiſhed in the Philoſophical Tranſactions, vol. 57. by Mr. Ellis, in a letter to Lord Hillſborough.

" This compound animal, which is of a tender fleſhy ſubſtance, conſiſts of many tubular bodies, ſwelling gently towards the upper part, and ending like a buſh or very ſmall onion; on the top of each is its mouth, ſurrounded by one or two rows of tentacles, or claws, which when contracted look like circles of beads.

" The lower part of all theſe bodies have a communication with a firm fleſhy wrinkled tube, which ſticks faſt to the rocks, and ſends forth other fleſhy tubes, which creep along them in various directions. Theſe are full of different ſizes of theſe remarkable animals, which riſe up irregularly in groups near to one another.

" This adhering tube, that ſecures them faſt to the rock, or ſhelly bottom, is worthy of our notice. The knobs that we obſerve, are formed in ſeveral parts of it by its inſinuating itſelf into the inequalities of the coral rock, or by graſping pieces of ſhells, part of which ſtill remain in it, with the fleſhy ſubſtance grown over them.

" This ſhows us the inſtinct of nature, that directs theſe animals to preſerve themſelves from the violence of the waves, not unlike the anchoring of muſcles, by their fine ſilken filaments that end in ſuckers; or rather like the ſhelly baſis of the ſerpula, or worm-ſhell, the tree-oyſter, and the ſlipper barnacle, &c. whoſe baſes conform to the ſhape of whatever ſubſtance they fix themſelves to, graſping it faſt with their teſtaceous claws, to withſtand the fury of a ſtorm.

" When we view the inſide of this animal diſſected lengthwiſe, we find like a little tube leading from the mouth to the ſtomach, from whence there riſe eight wrinkled ſmall guts, in a circular order, with a yellowiſh ſoft ſubſtance in them; theſe bend over in the form of arches towards the lower part of the bulb, from whence they may be traced downwards, to the narrow part of the upright tube, till they come to the fleſhy adhering tube, where ſome of them may be perceived entering into a papilla, or the beginning of an animal of the like kind, moſt probably to convey its nouriſhment till it is provided with claws: the remaining part of theſe ſlender guts are continued on in the fleſhy tube, without doubt for the ſame purpoſe of producing and ſupporting more young ones from the ſame common parent.

" The many longitudinal fibres that we diſcover lying parallel to each other, on the inſide of the ſemi-tranſparent ſkin, are all inſerted in the ſeveral claws round the animal's mouth, and are plainly the tendons of the muſcles for moving and directing the claws at the will of the animal: theſe may be likewiſe traced down to the adhering tube.

" As this ſpecimen has been preſerved in ſpirits, the colour of the animal, when living, cannot be certainly known; it is at preſent of a pale yellowiſh brown.

« With regard to its name, it may be called Actinia Sociata, or the Cluſter Animal-flower."

ANIMAL *Syſtem* denotes the whole claſs of beings endowed with animal life, otherwiſe called the *animal kingdom*.

ANIMALS, the preparation for collections or muſeums.

ANIMALCULE, in general, ſignifies a little animal; and thus the term might be applied to every animal which is ſcarce diſcernable to the naked eye. It hath been cuſtomary, however, to diſtinguiſh by the name of Animalculæ, ſuch animals as are of a ſize ſo diminutive, that their true figure can only be diſcerned with the aſſiſtance of glaſſes; and more eſpecially ſuch as are altogether inviſible to the naked eye.

By the help of magnifying glaſſes, we are brought into a kind of new world; where numberleſs animals are diſcovered, which from their minuteneſs muſt otherwiſe for ever have eſcaped our obſervation: and how many kinds of theſe inviſible creatures there may be, is ſtill unknown; as they are diſcerned of all ſizes, from thoſe which are barely inviſible to the naked eye, to ſuch as reſiſt the action of the microſcope, comparatively ſpeaking as the fixed ſtars do that of the teleſcope, and with the beſt magnifiers hitherto invented appear only as ſo many moving points.

The ſmalleſt living creatures our inſtruments can ſhow are thoſe that inhabit the waters: for though poſſibly animalculæ, equally minute, or perhaps more ſo, may fly in the air, or creep upon the earth, it is ſcarce poſſible to bring ſuch under our examination; but water being tranſparent, and confining the creatures in it, we are able, by applying a drop of it to the microſcope, to diſcover all that it contains. Some of the moſt curious of theſe animalculæ, which have been deſcribed by microſcopical obſervers, I ſhall here give an account of.

1. *The Hair-like Inſect.* This is ſo called, by Mr. Baker, on account of its ſhape; being extremely ſlender, and frequently an hundred and fifty times as long as broad. The body or middle part, which is nearly ſtraight, appears, in ſome, compoſed of ſuch rings as the windpipe of land-animals is made up of; but in others, ſeems rather ſcaly, or made up of rings, that obliquely croſs one another. Its two ends are hooked or bent, pretty nearly in the ſame degree, but in a direction oppoſite to each other; and as no eyes can be diſcerned, it is difficult to judge which is the head or tail. Its progreſſive motion is very ſingular, being performed by turning upon one end as a centre, and deſcribing almoſt a quarter of a circle with the other.

When viewed ſingly, they are exceedingly tranſparent, and of a beautiful green colour; but when numbers of them are brought together, they become opaque, loſe their green colour, and grow apparently black.

Notwithſtanding the extreme minuteneſs of theſe animalculæ, they ſeem to be fond of ſociety; for, after viewing for ſome time a parcel of them taken up at random, they will be ſeen diſpoſing themſelves in a kind of regular order. If a multitude of them are put into a jar of water, they will form themſelves into a regular body, and aſcend ſlowly to the top, where, after they have remained for ſome time expoſed to the air, their green colour changes to a beautiful ſky-blue: and, when they are weary of this ſituation, they form themſelves into a kind of rope, which ſlowly deſcends as low as they intend; but if they happen to be cloſe to the ſide of the jar, they will deſcend upon it. They are ſo nearly of the ſpecific gravity of water itſelf, that they will either remain at bottom, float upon the ſurface, or be ſuſpended in the middle, according as they are originally placed, or as they themſelves are inclined.

A ſmall quantity of the matter containing theſe animalculæ having been put into a jar of water, it ſo happened, that one part went down immediately to the bottom, whilſt the other continued floating on the top. When things had remained for ſome time in this condition, each of theſe ſwarms of animalculæ began to grow weary of its ſituation, and had an inclination to change quarters. Therefore, both armies ſet out at the ſame time, the one proceeding upwards, and the other downwards; ſo that, after ſome hours journey, they met in the middle; when the army that was marching upwards, opened to the right and left, to make room for thoſe that were deſcending. Thus, without confuſion or intermixture, each held on its way; the army that was going up, marching in two columns to the top, and the other proceeding in one column to the bottom, as if each had been under the direction of experienced leaders.

The hair-like inſect was firſt diſcovered in a ditch at Norwich, one end of which communicates with the river there, and the other end with a ſecond ditch, into which ſeveral kennels empty themſelves. The length of this ditch, when Mr. Baker wrote his account of theſe animalculæ, was one hundred yards, and its breadth nine.

2. *Eels in Paſte, &c.* When paſte is allowed to ſtand till it becomes ſour, it is then found to be the habitation of numberleſs animalculæ, which may be diſcerned by the naked eye; and though their form cannot be perfectly diſtinguiſhed, their motion is very perceptible, and the whole paſte will ſeem to be animated.

The moſt remarkable property of theſe inſects is, that they are viviparous. If one of them is cut through near the middle, ſeveral oval bodies of different ſizes will be ſeen to iſſue forth. Theſe are young anguillæ, each of them coiled up, and incloſed in its proper membrane, which is ſo exquiſitely fine, as ſcarce to be diſcernible by the beſt magnifier, while it incloſes the embryo animal.

The uterus, or veſſel, that contains all theſe oval bodies, is compoſed of many ringlets, not unlike the aſperia arteria of land animals, and ſeems to be conſiderably elaſtic; for as ſoon as the animalculæ is cut in two, the oval bodies are thruſt out with ſome degree of violence, from the ſpringing-back or action of this bowel. An hundred and upwards of the young ones have been ſeen to iſſue from the body of one ſingle eel, whereby the prodigious increaſe of them may be eaſily accounted for.

Animalculæ of a ſimilar kind are likewiſe found in vinegar; and, like thoſe already deſcribed, are found to be viviparous. But it is not only in acid matters that ſuch appearances are obſerved. In ſome fields of wheat, many grains may be obſerved, that appear blackiſh outwardly, as if ſcorched; but, when opened, are found to contain a ſoft white ſubſtance, which, attentively conſidered, appears to be nothing elſe than a congeries of threads of threads or fibres, lying cloſe to each other in a parallel direction, much reſembling the unripe down of ſome thiſtles on cutting open the flower-heads before they begin to blow.

This fibrous matter diſcovers not the leaſt ſign of life or motion, unleſs when water is applied; but immediately on wetting, provided the grains of wheat have been newly gathered, the ſuppoſed fibres ſeparate, and appear to be living creatures. Their motions at firſt are very languid; but gradually become more vigorous, twiſting and wriggling themſelves ſomewhat in the manner of the eels in paſte, but always ſlower, and with leſs regularity.

3. *The Proteus.* This animalculæ has been dignified by Mr. Baker with the name of Proteus, on account of its aſſuming a great number of different ſhapes, ſo as ſcarce to be known as the ſame animal in its various transformations; and, indeed, unleſs it be carefully watched while paſſing from one ſhape to another, it will often become ſuddenly inviſible.

When water, wherein any ſort of vegetable has been infuſed, or animals preſerved, has ſtood quietly for ſome days, or weeks, in a glaſs or other veſſel, a ſlimy ſubſtance will be collected about the ſides; ſome of which, being taken up with the point of a penknife, placed on a ſlip of glaſs in a drop of water, and looked at through the microſcope, will be found to harbour ſeveral kinds of little animals, that are ſeldom found ſwimming about at large; among which the proteus is one. Its ſubſtance and colour ſeems to reſemble that of a ſnail; and its whole ſhape ſeems to bear a conſiderable reſemblance to that of a ſwan. It ſwims to and fro with great vivacity, but will now and then ſtop for a minute or two; during which time its long neck is uſually employed as far it can reach, forwards, and on every ſide, with a ſomewhat ſlow, but equable motion, like that of a ſnake, frequently extending thrice the length of its body, and ſeemingly in ſearch of food.

There are no eyes, nor any opening in the head like a mouth, to be diſcerned; yet its actions plainly prove it to be an animal that can ſee.

When it is alarmed, it ſuddenly draws in its long neck, and when it has continued ſome time in this poſture, it will often, inſtead of the head and neck it had formerly, put forth a new one, with a kind of wheel machinery, the motions of which draw a current of water to it from a conſiderable diſtance. Having often pulled in and thruſt out this ſhort head, ſometimes with and ſometimes without the wheel-work, the creature, as if weary, will remain motionleſs for a while; then its head and long neck will be very ſlowly protruded, and it ſoon reſumes its former agility.

4. *The Wheel-Animal, or Vorticellæ.* This wonderful animalculæ is found in rain water that has ſtood ſome days in leaden gutters, or in hollows of lead on the tops of houſes; or in the ſlime or ſediment left by ſuch water; but if the water ſtanding in gutters of lead, or the ſediment left behind it, has any thing of a red colour in it, one may be certain of finding them in it. Though it diſcovers no ſigns of life except when in the water, yet it is capable of continuing alive for many months after it is taken out of the water, and kept as dry as duſt.

In this ſtate it is of a globular ſhape, and exceeds not the bigneſs of a grain of ſand; but, being put into water, in the ſpace of half an hour, a languid motion begins, the globule turns itſelf about, lengthens itſelf by ſlow degrees, aſſumes the form of a lively maggot, and moſt commonly in a few minutes afterwards puts out its wheels; ſwimming vigorouſly through the water, as if in ſearch of food; or elſe, fixing itſelf by the tail, works the wheels in ſuch a manner as to bring its food to it.

The moſt remarkable part of this animalculæ is its wheelwork; which conſiſts of a couple of ſemicircular inſtruments, round the edges of which many little fibrillæ move themſelves very briſkly, ſometimes with a kind of rotation, and ſometimes in a trembling or vibrating manner. When in this ſtate, it ſometimes unfaſtens its tail, and ſwims along with a great deal of ſwiftneſs, ſeemingly in purſuit of its prey. At other times the wheels ſeem to be entire circles, armed with ſmall teeth like thoſe of the balance-wheel of a watch, appearing projected forwards beyond the head, and extending ſideways ſomewhat wider than its diameter. The teeth or cogs of theſe wheels are at an equal diſtance: but the figure of them varies according to their poſition, the degree of their protruſion, and perhaps the will of the animal itſelf. They appear ſometimes like minute oblong ſquares, riſing at right angles from the periphery of a circle, like ancient battlements on a round tower; and at other times they terminate in ſharp points, and all together reſemble a kind of gothic crown. They are often ſeen in a kind of curvular direction, all bending the ſame way, and ſeeming like ſo many hooks; and now then the ends of them will be perceived to be clubbed like mallets.

As theſe wheels are every where exceſſively tranſparent, except about their circular rim or edge, where the cogs are ſet, it is very difficult to determine by what contrivance they are turned about, or what their real figure is, though they ſeem exactly to reſemble wheels moving round upon an axis. The difficulty of conceiving how an articulation could be contrived ſo as to cauſe a real rotation, hath cauſed many people imagine that there was a deception in this caſe: but Mr. Adams and Mr. Baker aſſures us, that when the wheels are fully protruded, they never fail to ſhow all the viſible marks of a regular rotation; and, in ſome poſitions, the ſame cogs or teeth may be traced by the eye during a complete revolution.

All the actions of this creature ſeem to imply ſagacity and quickneſs of ſenſation: for at the leaſt motion in the water, they inſtantly draw in their wheels, whilſt maggot-ſtate, its motions are ſlow and irregular; but, after the wheels are protruded, they are performed with great regularity and ſwiftneſs.

Notwithſtanding the minuteneſs of this animalculæ, the microſcope generally diſcovers others in the ſame drop of water, compared with which the wheel-animal may be ſaid to be a whale.

The tranſparency of its body, allows its internal parts to be ſeen, which cannot be perceived in the minuteſt animalculæ on account of the ſmallneſs of their ſize.

The alternate motions of contraction and dilatation are performed with great ſtrength and vigour, in pretty much the ſame time as the pulſation of the arteries of a man in health. The motions of the heart are communicated to all the internal parts of the thorax; and ſeem to extend a great deal further; for a ſtrict examination diſcovers, at the ſame time, throughout the whole animal, contractions and dilatations going on, that are apparently correſpondent thereto. However, theſe motions of the heart are ſometimes ſuſpended, or imperceptible, for two or three minutes; after which they are renewed, and go on again with the ſame regularity as before.

The blood or circulating fluid of the wheel-animal is ſo abſolutely colourleſs, that the current of it through the veſſels is indiſtinguiſhable by the microſcopes.

Beſides the abovementioned animalculæ, there are found in the waters ſeveral other ſpecies of animals furniſhed with wheels, ſome of which appear to have a rotatory, and others a vibratory, motion.

5. *The Bell-flower Animal*, or *Plumed Polype*. Theſe animalculæ dwell in colonies together, from ten to fifteen, ſeldom falling ſhort of the former number, or exceeding the latter, in a ſlimy kind of mucilaginous or gelatinous caſe; which, out of the water, has no determined form, appearing like a little lump of ſlime; but when expanded therein, has ſome reſemblance to the figure of a bell with its mouth upwards; and is uſually about half an inch long, and a quarter of an inch in diameter. Theſe bells, or colonies, are to be found adhering to the large leaves of duckweed, and other aquatic plants.

The bell, or caſe, which theſe animals inhabit, being very tranſparent, all the motions of its inhabitants may be diſcerned through it diſtinctly. It ſeems divided internally into ſeveral apartments, or rather to contain ſeveral ſmaller ſacculi, each of which incloſes one of theſe animals. The openings at the tops of theſe ſacculi, are but juſt ſufficient to admit the creature's head and a ſmall part of its body to be thruſt out beyond them, the reſt remaining always in the caſe. It can, however, occaſionally retire into its caſe altogether; and never fails to do ſo when alarmed by any ſudden motion of the water, or of the veſſel which contains it.

Beſides the particular and ſeparate motion which each of theſe creatures is able to exert within its own caſe, independent of the reſt; the whole colony together have a power of altering the poſition of the bell, or even of removing it from one place to another; ſo that this bell is ſometimes found ſtanding perfectly upright, and at other times bending the upper part downwards. As theſe animalculæ ſeem not to chooſe to ſtay together in ſocieties whoſe number exceeds 15, when the colony happens to increaſe in number, the bell may be obſerved to ſplit gradually, beginning from about the middle of the upper or anterior extremity, and proceeding downwards towards the bottom, till they at laſt ſeparate entirely, and become too complete colonies independent of each other.

The arms of each individual of this colony are ſet round the head, to the number of 40, having each the figure of an Italic *ſ*, one of whoſe hooked ends is faſtened to the head; and all together, when expanded, compoſe a figure ſhaped ſomewhat like a horſe's ſhoe, convex on one ſide next the body, but gradually opening and turning outwards, ſo as to leave a conſiderable area within the outer extremities of the arms. When the arms are thus extended, the creature, by giving them a vibrating motion, can produce a current in the water, which brings the animalculæ or whatever other minute bodies are within the ſphere of its action, with great velocity to its mouth, ſituated between the arms; where they are taken in, if liked, or driven away by a contrary motion.

The food is conveyed immediately from the mouth or opening between the arms, through a narrow neck, into a paſſage ſeemingly correſpondent to the œſophagus in land-animals; down which it paſſes into the ſtomach, where it remains for ſome time, and then is voided upwards, in ſmall round pellets, through a gut whoſe exit is near the neck.

The body conſiſts of three diviſions; in the uppermoſt of which are contained all the abovementioned inteſtines, which are only to be diſcerned when the creature is full, at which time they become opaque. The other two diviſions, ſeem to be of no other uſe than to give the creature a power of contraction and extenſion. The arms are not able to contract like thoſe of the common polype; but, when the animal retires into its caſe, they are brought together in a cloſe and curious order, ſo as to be eaſily drawn in. Though their general appearance when expanded is that of a cup whoſe baſe and top are of an horſe-ſhoe form, they ſometimes ſeparate into four parts, and range themſelves ſo as to reſemble four ſeparate plumes of feathers.

6. *The Globe Animal.* This animalculæ, ſeems exactly globular, having no appearance of either head, tail or fins. It moves in all directions, forwards or backwards, up or down, either rolling like a bowl, ſpinning horizontally like a top, or gliding along ſmoothly without turning itſelf at all. Sometimes its motions are ſlow, at other times very ſwift; and when it pleaſes, it can turn round, as it were upon an axis, very nimbly, without removing out of its place.

The ſurface of the whole body appears, in ſome, as if all over dotted with points; in others, as if granulated like ſhagreen: but their more general appearance is, as if beſet thinly round with ſhort moveable hairs or briſtles, which probably are the inſtruments by which their motions are performed. Theſe animalculæ may be ſeen by the naked eye, but appear only like moving points.

7. *The Pipe Animal.* Theſe creatures are found on the coaſt of Norfolk, living in ſmall tubes or caſes of ſandy matter, in ſuch multitudes as to compoſe a maſs ſometimes of three feet in length. Some of theſe tubes are found petrified, and conſtitute one ſpecies of ſyringoides.

8. *An Inſect with net-like Arms.* The properties and ſhape of this little animal are very extraordinary. It is found only in caſcades, where the water runs very ſwift, where they appear in cluſters, ſtanding erect on their tails; and reſembling, when all together, the combs of the bees at the time they are filled with aureliæ. On being taken out of the water, they ſpin threads, by which they hang exactly in the ſame manner as the garden-ſpider. The body appears curiouſly turned as on a lath; and at the tail are three ſharp ſpines, on which it raiſes itſelf, and ſtands upright in the water: but the moſt curious apparatus is about its head, where it is furniſhed with two inſtruments like fans or nets, which ſerve to provide its food; which it frequently ſpreads out and draws in again; and when drawn up they are folded together with the utmoſt nicety and exactneſs, ſo as to be indiſcernible when brought cloſe to the body.

At the bottom of theſe fans a couple of claws are faſtened to the lower part of the head, which, every time the nets are drawn in, conduct to its mouth whatever is taken in them. When it does not chuſe to employ its nets, it thruſts out a pair of ſharp horns.

9. A *curious aquatic Worm*, which is found in ditch-water; and is of various ſizes, from $\frac{1}{40}$ to $\frac{1}{2}$ an inch in length. About the head it has ſomewhat of a yellowiſh colour; but all the reſt of the body is perfectly colourleſs and tranſparent, except the inteſtines, which are conſiderably opaque.

Along its ſides are ſeveral papillæ, with long hairs growing from them; it has two black eyes, and it is very nimble. But the moſt remarkable thing in this creature is a long horn or proboſcis; which, in the large ones, may be ſeen with the naked eye, if the water is clear, and is ſometimes $\frac{1}{10}$ of an inch in length: this it waves to and fro as it moves in the water.

10. *Spermatic Animals*, and *Animalcula Infurſoria*. The diſcovery of living animalculæ in the ſemen of moſt animals is claimed by Mr. Lewenoek who made this diſcovery about the beginning of 1678.

According to this naturaliſt, theſe animalculæ are found in the ſemen maſculinum of every kind of animals, but their general appearance is very much the ſame, nor doth their ſize differ in proportion to the bulk of the animal to which they belong.

The bodies of all of them ſeem to be of an oblong oval form, with long tapering ſlender tails iſſuing from them; and as by this ſhape they reſemble tadpoles, they have been frequently called by that name; though the tails of them, in proportion to their bodies, are much longer than the tails of tadpoles are: and it is obſervable, that the animalculæ in the ſemen of fiſhes have tails much longer and more ſlender than the tails in other animals; inſomuch, that the extremity of them is not to be diſcerned without the beſt glaſſes, and the utmoſt attention.

The numbers of theſe animalculæ are inconceivable. On viewing with a microſcope the milt or ſemen maſculinum of a living cod-fiſh innumerable multitudes of animalculæ were found therein, of ſuch a diminutive ſize that he ſuppoſed at leaſt 10,000 of them capable of being contained in the bulk of a drop of water; whence he concludes, that the milt of this ſingle fiſh contained more living animalculæ than there are to be found people in the whole world.

To find the comparative ſize of theſe animalculæ Mr. Lewenhoek placed an hair of his head near them; which hair, through his microſcope, appeared an inch in breadth; that at leaſt 60 ſuch animalculæ could eaſily lie within that diameter, whence their bodies being ſpherical, it follows, that 216,000 of them are but equal to a globe whoſe diameter is the breadth of a hair.

Theſe animalculæ appear to be very vigorous, and tenacious of life; for they may be obſerved to move long after the animal from which they are taken is dead.

They have this peculiarity alſo, that they are continually in motion, without the leaſt reſt or intermiſſion, provided there is fluid ſufficient for them to ſwim about in.

The *Animalcula Infuſoria,* take their name from their being found in all kinds either of vegetable or animal infuſions. For there is ſcarce any kind of water, unleſs impregnated with ſome mineral ſubſtance, but what will diſcover living creatures.

The production of *animalcula infuſoria* is very ſurpriſing. In four hours time, an infuſion of cantharides has produced animalculæ leſs than even the tails of the ſpermatic animals already deſcribed. Neither do they ſeem to be ſubject to the fate of other animals; but enjoy a ſort of immortality. Nor do the common methods by which other animals are deſtroyed, ſeem to be effectual for deſtroying their vital principle. Hot mutton-gravy, ſecured in a phial with a cork, and afterwards ſet among hot aſhes to deſtroy as effectually as poſſible every living creature that could be ſuppoſed to exiſt in it, has nevertheleſs been found ſwarming with animalculæ after ſtanding a few days.

ANIMALCULÆ *Inviſible.* Naturaliſts ſuppoſe another ſpecies or order of inviſible animalculæ, viz. ſuch as eſcape the cognizance even of the beſt microſcopes, and give many probable conjectures in relation to them. Reaſon and analogy give ſome ſupport to the exiſtence of infinite imperceptible animalculæ. The naked eye, ſay ſome, takes in from the elephant to the mite; but there commences a new order reſerved only for the microſcope, which comprehends all theſe from the mite to thoſe 27 millions of times ſmaller; and this order cannot be yet ſaid to be exhauſted, if the microſcope be not arrived at its laſt perfection.

[*We have in the foregoing account given the* general characters *of that numerous kingdom of nature called Animalculæ, or at leaſt ſo much as we judge uſeful in this place. It is neceſſary to remark, that, had a particular deſcription been given, under this head, it would require a volume in itſelf to enumerate the properties of this claſs of animals.*

For the entertainment of thoſe who are curious in exploring the wonders of creation, we have already introduced a plate of Animalculæ, in this work, which comes under the article Microſcopical Objects, and which will be illuſtrated there, with a particular deſcription; as we can with propriety, under that head, enter into a minute detail, as the ſubjects we have ſelected for this purpoſe are but few and curious.

There are not many of the Naturaliſts who have found out the relative properties of this minute Claſs of Animals. Mr. Adams, *of Fleet-ſtreet, and Mr.* Baker, *have thrown the greateſt lights upon this kingdom of reputed inviſibility.*]

ANIMATED, or ANIMATE, in a general ſenſe, denotes ſomething endowed with animal life. It alſo imports a thing to be impregnated with vermin or animalculæ.

ANIMATION, ſignifies the informing an animal body with a ſoul. The different hypotheſes of phyſicians and philoſophers, concerning the time of animation, have had their influence on the penal laws made againſt artificial abortions; it having been made capital to procure miſcarriage in the one ſtate, while in the other it was only deemed a venial crime.

ANIME, in heraldry, a term uſed when the eyes of a rapacious creature are borne of a different tincture from the creature itſelf.

ANIME, a reſin exſuding from the trunk of a large American tree called by Piſo, jetaiba, by the Indians, courbaril, which is a ſpecies of HYMENÆA. This reſin is of a tranſparent amber colour, a light agreeable ſmell, and little or no taſte. It diſſolves entirely, in rectified ſpirit of wine; the impurities, which are often in large quantities, remaining behind.

ANIMELLÆ, in anatomy, ſignifies the glands under the ears.

ANIMETTA, among eccleſiaſtical writers, denotes the cloth wherewith the cup of the euchariſt is covered.

ANINGA, in commerce, a root which grows in the Antilles iſlands, and is pretty much like the China plant. It is uſed by ſugar-bakers for refining the ſugar.

ANISUM, or ANISE, the ſame as Pimpinella.

ANKER, a liquid meaſure at Amſterdam. It contains about 32 gallons Engliſh meaſure.

ANKLE, in anatomy, the joint which connects the foot to the leg.

ANN, or ANNAT, in the Scotch law, ſignifies half a year's ſtipend, which the law gives to the executors of miniſters of the church of Scotland, over and above what was due to the miniſter himſelf, for his incumbency.

ANNALE, in the church of Rome, a term applied to the maſſes for the dead during a whole year after the perſon's deceaſe.

ANNALIS CLAVUS, in Roman hiſtory, the nail which the Prætor, Conſul, or Dictator, drove into the wall of Jupiter's temple annually upon the Ides of September, to ſhow the number of years. But this cuſtom was ſuperſeded by reckoning years by conſulſhips.

ANNALS, in literature, ſignify a ſpecies of hiſtory, which relates events in the chronological order wherein they happened. They differ from perfect hiſtory in this, that annals are but a bare relation of what paſſes every year, as a journal is of what paſſes every day; whereas hiſtory relates not only the tranſactions themſelves, but alſo the cauſes, motives, and ſprings of actions. Annals require nothing but brevity; hiſtory demands ornament.

ANNATES, among eccleſiaſtical writers, a year's income of a ſpiritual living.

In ancient times, theſe were given to the pope throughout all chriſtendom, upon the deceaſe of any biſhop, abbot, or pariſh clerk, and were paid by his ſucceſſor.

At the reformation they were taken from the pope, and veſted in the king; but queen Anne reſtored them to the church, by appropriating them to the augmentation of poor livings, generally called queen Anne's bounty.

ANNEALING, by workmen, alſo called nealing, is particularly uſed in making glaſs: it conſiſts in placing the bottles, &c. whilſt hot, in a kind of oven or furnace, were they are ſuffered to cool gradually; they would otherwiſe be too brittle for uſe. Metals are rendered hard and brittle by hammering: they are therefore made red hot, in order to recover their malleability; and this is likewiſe called nealing.

The difference between unannealed and annealed glaſs, with reſpect to brittleneſs, is very remarkable; for when an unannealed glaſs-veſſel is broken, it often flies into a ſmall powder, with a violence ſeemingly very diſproportioned to the ſtroke it has received. In general, it is in greater danger of breaking from a very ſlight ſtroke than from one of ſome conſiderable force. One of thoſe veſſels will often reſiſt the effects of a piſtol bullet dropt into it from the height of two or three feet; yet a grain of ſand falling into it, will make it burſt into ſmall fragments. This takes place ſometimes immediately on dropping the ſand into it: but often the veſſel will ſtand for ſeveral minutes after, ſeemingly ſecure; and then, without any new injury, it will fly to pieces.

The ſame phenomena are ſtill more ſtrikingly ſeen in glaſs drops or tears. They are globular at one end, and taper to a ſmall tail at the other. They are the drops which fall from the melted maſs of glaſs on the rods on which the bottles are made. They drop into the tubs of water which are uſed in the work; the greater part of them burſt immediately in the water. When thoſe that remain entire are examined, they diſcover all the properties of unannealed glaſs in the higheſt degree. They will bear a ſmart ſtroke on the thick end without breaking; but if the ſmall tail be broken, they burſt into ſmall powder with a loud exploſion. They appear to burſt with more violence, and the powder is ſmaller in an exhauſted receiver than in the open air. When they are annealed, they loſe thoſe properties.

Glaſs is one of thoſe bodies which increaſe in bulk when paſſing from a fluid to a ſolid ſtate. When it is allowed to cryſtallize regularly, the particles are ſo arranged, that it has a fibrous texture: it is elaſtick, and ſuſceptible of long continued vibrations; but when a maſs of melted glaſs is ſuddenly expoſed to the cold, the ſurface cryſtalizes, and forms a ſolid ſhell round the interior fluid parts: this prevents them from expanding when they become ſolid. They, therefore, have not the opportunity of a regular cryſtallization; but are compreſſed together with little mutual coheſion: on the contrary, they preſs outward to occupy more ſpace, but are prevented by the external cruſt. In conſequence of the effort of expanſion in the internal parts, the greater number of glaſs drops burſt in cooling; and thoſe which remain entire are not regularly cryſtallized.

By the proceſs of annealing, the glaſs is kept for ſome time in a ſtate approaching to fluidity; the heat increaſes the bulk of the cryſtallized part, and renders it ſo ſoft, that the internal parts have the opportunity of expanding aud forming a regular cryſtallization.

A ſimilar proceſs is now uſed for rendering kettles and other veſſels of caſt iron leſs brittle.

When caſt iron is broken, it has the appearance of being compoſed of grain: forged or bar iron appears to conſiſt of plates. Forged iron has long been procured, by placing a maſs of caſt iron under large hammers, and making it undergo violent and repeated compreſſion. A proceſs is now uſed for converting caſt iron into forged by heat alone. The caſt iron is placed in an air-furnace, and kept for ſeveral hours in a degree of heat, by which it is brought near to a fluid ſtate. It is then allowed to cool gradually, and is found to be converted into forged iron. This proceſs is conducted under a patent; although, if Reaumur's experiments upon caſt iron be conſulted, it will appear not to be a new diſcovery.

Caſt-iron, is brittle, becauſe it has not had the opportunity of cryſtallizing regularly. For when it is expoſed to cold, while fluid, the ſurface becoming ſolid, prevents the inner part from expanding and arranging themſelves into regular cryſtals. And when caſt iron is brought near to the melting-point, and continued for a ſufficient length of time in that degree of heat, the particles have the opportunity of arranging themſelves into that form of cryſtals by which forged-iron is diſtinguiſhed, and by which it poſſeſſes coheſion and all its properties.

Annealing of iron may be proved from the well-known fact of forged-iron being incomparably more difficult of fuſion than caſt-iron. Iron diminiſhes in bulk when it paſſes into a fluid ſtate, while moſt other metals increaſe in volume.

Many attempts have been made to procure a maſs of it in a malleable ſtate, but without ſucceſs. It is ſaid that the proceſs is now diſcovered by a chemiſt in Spain. The treatment of the metal is probably very ſimple. Perhaps it only conſiſts in precipitating it in a minute powder from aqua regia, expoſing it to a ſtrong heat which melts it, and keeping it for ſome time in a ſtate nearly fluid, that it may, like iron, cryſtallize regularly: by this it will poſſeſs all its metallic properties.

St. **ANN**'s *Day*, a feſtival of the Chriſtian church, celebrated by the Latins on the 26th of July, but by the Greeks on the 9th of December. It is kept in honour of Anna, mother of the Virgin Mary.

ANNEXATION, in law, a term uſed to imply the uniting of lands to the crown.

ANNEXED, in a general ſenſe, implies a thing joined to ſomething elſe.

ANNIHILATION, the act of reducing any created being into nothing.

ANNI NUBILES, in law, denotes the marriageable age of a woman; viz. after ſhe has arrived at the age of twelve years.

ANNIENTED, in law, ſignifies annulled or made void.

ANNIVERSARY, the annual return of any remarkable day.

ANNIVERSARY DAYS, in old times, denoted thoſe days in which an office was yearly performed for the ſouls of the deceaſed, or the martyrdom of the ſaints was yearly celebrated in the church.

ANNO DOMINI, i. e. the year of our Lord; the computation of the time from our Saviour's incarnation.

ANNOISANCE, in law, implies the ſame as NUISANCE.

ANNOMINATION, in rhetoric, the ſame with what is otherwiſe called Paronomaſia.

ANNONA, in Roman antiquity, denotes proviſion for a year of all ſorts, but eſpecially of corn.

ANNONA, is likewiſe the allowance of oil, ſalt, bread, fleſh, corn, wine, hay, and ſtraw, which was annually provided by the contractors for the maintenance of an army.

ANNONA, the Cuſtard Apple, a genus of the polygynia order, belonging to the polyandria claſs of plants; and, in the natural method, ranking under the 52d order, Coadunatæ. For the characters ſee Syſtem of BOTANY. There are eight ſpecies.

1. The reticulata, or cuſtard-apple, is a native of the Weſt-Indies, where it grows to the height of twenty-five feet, and is well furniſhed with branches on every ſide. The bark is ſmooth, and of an aſh-colour; the leaves are of a light green, oblong, and have ſeveral deep tranſverſe ribs or veins, ending in acute points; the fruit is of a conical form, as large as a tennis-ball, of an orange colour when ripe, having a ſoft, ſweet, yellowiſh pulp, of the conſiſtence of a cuſtard, from whence it has its name.

2. The muricata, or ſour-ſop, rarely riſes above twenty feet high, and is not ſo well furniſhed with branches as the other,

3. The ſquamoſa, or ſweet ſop, ſeldom riſes higher than fifteen feet, and well furniſhed with branches on every ſide.

4. The paluſtris, or water-apple, grows to the height of thirty or forty feet.

5. The cherimola, with oblong ſcaly fruit, is a native of Peru, where it is much cultivated for the fruit, and grows to be a very large tree well furniſhed with branches.

6. The Africana, with ſmooth blueiſh fruit.

7. The Aſiatica, or purple apple. This grows in ſome of the French iſlands, as alſo in Cuba, in great plenty.

8. The triloba, or North-American annona, called by the inhabitants papaw, is a native of the Bahama iſlands, and likewiſe of Virginia and Carolina. The fruit grows in cluſters of three, and ſometimes of four together; when ripe, they are yellow, covered with a thin ſmooth ſkin, which contains a yellow pulp, of a ſweet luſcious taſte. In the middle of this pulp, lie in two rows twelve ſeeds, divided by as many thin membranes.

The laſt ſort will thrive in the open air in Britain, if it is placed in a warm and ſheltered ſituation; but the plants ſhould be trained up in pots, and ſheltered in winter for two or three years, till they have acquired ſtrength. All the other ſorts require to be kept in a warm ſtove, or they will not live in this country.

ANNONÆ PRÆFECTUS, in antiquity, an extraordinary magiſtrate, whoſe buſineſs it was to prevent a ſcarcity of proviſion, and to regulate the weight and fineneſs of bread.

ANNOTATION, in matters of literature, is a brief commentary, or remark, upon a book or writing, in order to clear up ſome paſſage, or draw ſome concluſion from it.

ANNOTTO, in commerce, the ſame as ANOTTO.

ANNUAL, in a general ſenſe, an appellation given to whatever returns every year, or is always performed within that ſpace of time.

ANNUAL LEAVES, are ſuch leaves as come up afreſh in the ſpring, and periſh in winter. Theſe ſtand oppoſed to ever-greens.

ANNUAL PLANTS, called alſo ſimply annuals, are ſuch as only live their year, i. e. come up in the ſpring, and die again in the autumn; and accordingly are to be recruited every year.

ANNUAL RENT, implies a yearly profit due by a debtor in a ſum of money to a creditor for the uſe of it.

Right of **ANNUAL RENT**, implies the original method of charging lands with a yearly payment for the loan of money, before the taking of intereſt for money was allowed by the ſtatute.

ANNUALIA, yearly oblations anciently made by the relations of the deceaſed.

ANNUEL, of Norway, of which mention is made in the acts of parliament of king James III. of Scotland, was an annual payment of an hundred marks ſterling, which the kings of Scotland were obliged to pay to the kings of Norway, in ſatisfaction for ſome pretenſions which the latter had to the Scottiſh kingdom, by virtue of a conveyance made thereof by Malcolm Kenmore, who uſurped the crown after his brother's deceaſe. This annuel was firſt eſtabliſhed in 1266; in conſideration whereof the Norwegians renounced all title to the ſucceſſion of the iſles of Scotland. It was paid till the year 1468, when the annuel, with all its arrears, was renounced in the contract of marriage between king James III. and Margaret, daughter of Chriſtian I. king of Norway, Denmark, and Sweden.

ANNUENTES MUSCULI, in anatomy, a pair of tranſverſe muſcles at the root of the vertebræ of the back, called Recti interni minores.

I enjoy the pleaſing expectation that the following Syſtem will be acceptable to the numerous readers of this work, as it is of an intereſting nature, and is requiſite to be known by every perſon of property.

I am the more emboldened in this expectation, as I have introduced the whole doctrine of Annuities with Brevity, Novelty, and Accuracy; avoiding the errors of other writers, and incorporating what is not to be met with in any Publication on this ſubject.

The 1ſt and 2d Tables in this Syſtem exhibit the amount and value of Annuities for years certain, and I have alſo applied them to caſes of intereſt, a thing which I believe has not been done before; by which two needleſs tables are ſaved.

The 3d and 4th Tables ſhew the Probability of Life, at all Ages, according to the bills of mortality at London and Northampton; the former I have ſelected from Mr. Simpſon's Treatiſe, and the latter from that of Dr. Price.

The 5th Table exhibits the Expectation of Life at every Age, according to the aforeſaid Bills, and includes both Mr. Simpſon's and Dr. Price's.

Table 6th, gives the Value of an Annuity for a ſingle Life of any Age, at the different rates of 3, 4, and 5 per Cent. Intereſt, both according to the London and Northampton Bills.

The laſt Table ſhews the value of an Annuity upon the joint continuance of two lives, according to the London and Northampton bills of mortality; and for the aforeſaid rates of intereſt. It compriſes the ſubſtance of 13 or 14 of Doctor Price's Tables, along with that of Mr. Simpſon, which mode of arrangement cannot fail of being extremely uſeful, as their difference in every caſe is diſcovered at one view.

Other Tables of Mr. Simpſon and Dr. Price, which appeared ſuperfluous, I have expunged; and have advanced correct methods for ſolving the ſame Problems for which they were intended, by means of thoſe Tables that are here given, ſo that brevity and comprehenſiveneſs are obſerved through the whole.

In the printing of the Tables, I have paid a moſt particular attention to the correcting of the preſs, a matter of the utmoſt import in calculations. And, indeed, my caſe in this particular, has been ſuch, that I dare, with confidence, affirm, that the Tables concerned in this Syſtem, are more correct than in Dr. Price's *laſt edition, as I have here rectified ſome typographical faults which appear in his Treatiſe.*

I have ſhewn theſe Tables to C. Brand, Eſq. of the Amicable Society for the Perpetual Aſſurance on Lives, (the gentleman who reviſed, corrected, improved, and enlarged the laſt edition of Smart's Tables of Intereſt, Annuities, &c.) who has honoured them with his inſpection and approbation, and whoſe ſanction gives me pleaſure, as I conſider they have undergone the teſt of critic examination.

Excise-Office, Broad-ſtreet.

ROBERT MOODY.

A NEW SYSTEM of ANNUITIES.

WHEN a ſum of money is to be paid annually to any perſon for a term of years, or for life, it is called an Annuity. The differences between a rent and an Annuity, in law, are, 1ſt. That every rent is conſidered as ariſing from, and going out of the land; but an Annuity charges only the granter or his heirs that have aſſets by decent; 2dly, That for the recovery of an annuity, no action lies, but only the writ of annuity againſt the granter, his heirs, or ſucceſſors; but of rent, the ſame actions lie as do of land: and 3dly, That an annuity is never taken for aſſets, becauſe it is no freehold in law, nor can be put in execution upon a ſtatute merchant, ſtatute ſtaple, or elegit, as a rent may be.

It is however frequently ſo ordered, that payments of this ſort, are to be made quarterly, or half yearly, in which caſes there ſeems ſome degree of impropriety in the term Annuity; for the expreſſion, "a Quarterly Annuity," is certainly a Soleciſm.

The calculation or doctrine of Annuities is diſtinguiſhed into two parts; namely, Annuities certain, and Annuities contingent; the former commencing and expiring with ſome given term of years; the latter either commencing or expiring on the deceaſe of ſome perſon or perſons concerned, or being dependent on ſuch perſon or perſon's ſurviving a certain age, &c. I ſhall treat of them both in their diſtinct order.

CHAP. I.

ANNUITIES CERTAIN.

PROBLEM I.

To find what an Annuity unpaid for a given Term of Years amounts to at a given Rate of Intereſt.

Remark. When it is a real caſe that an annuity has actually been unpaid for a certain number of years, the perſon entitled thereto cannot legally demand more, than the amount at ſimple intereſt; to find which, obſerve this Rule.

Let the rate of intereſt for 1l. the annuity, and the time, be multiplied together, and let $\frac{1}{2}$ this product be multiplied by the time, leſs 1, ſo will the reſult be the intereſt depending, to which add the product of the annuity by the time, and the ſum will be the amount.

N. B. In this rule the time is ſuppoſed to be complete years. If the time, however, in any caſe conſiſts of years and parts of a year, the amount for whole years muſt be calculated according to this method, and a proportional part of the annuity, according to the rule of three (allowing diſcount) muſt be taken for the remainder.

Examp. What will an annuity of 50£. amount to at the end of eight years, at the rate of 5 per cent. per annum, ſimple intereſt. Here, intereſt being at 5 per cent. the rate for 1£. is .05; and $.05 \times 50 \times 8 = 20$; and the half thereof, 10, multiplied by $8 - 1\ (7) = 70$ £. the intereſt; to which add 50×8, (400) and the ſum is 470; the amount required.

N. B. Simple intereſt being wholly unequitable, it is never admitted, neither indeed ought it to be in annuity-calculations, except in caſes ſimilar to the above, where the legiſlature for certain reaſons has ſo appointed it.

Scholium. If the payments are half yearly, or quarterly, then, in applying the above rule, the double or quadruple of the time muſt be uſed in lieu of the time, and the quarterly or half yearly payment, muſt be uſed inſtead of the annuity.

PROBLEM II.

The ſame Caſe given as above to find the Amount at Compound Intereſt.

Rule. Multiply the amount of 1£. for one year, as often into itſelf as there are years, leſs 1; or which is the ſame, raiſe it to the power whoſe index is equal to the number of years; from the reſult ſubtract 1, and divide the remainder by the intereſt of 1£. for a year; then multiply the quotient by the annuity, and the product will be the amount required.

Examp. What is the amount of an annuity of 50£. for three years, at 5 per cent. compound intereſt. Here the amount of 1£. for one year is 1.05, and this multiplied twice into itſelf, (viz. cubed) the reſult = 1.157625; and this, leſs 1, = .157625; which, divided by .05, the quotient is 3.1525, and this multiplied by 50, the product is 157.625£; or 157*l.* 12*s.* 6*d.* the anſwer ſought.

Scholium. If the payments are half yearly or quarterly, take the amount and intereſt of 1£. for half or quarter of a year and uſe them in the above rule, inſtead of the amount and intereſt for a year; alſo take the double or quadruple of the time, in lieu of the time; and the rule will hold good.

N. B. The amount of 1l. for half a year at compound intereſt, is equal to the ſquare root of the amount for a year; and the amount for a quarter of a year is equal to the ſquare root of the amount for half a year. The amount of 1l. leſs 1, is equal to the intereſt.

The amount of 1*l.* for $\frac{1}{4}$ and $\frac{1}{2}$ a year, reſpectively,

	3perCent	3$\frac{1}{2}$ per C.	4perCent	4$\frac{1}{2}$ per C.	5perCent
$\frac{1}{4}$ year	1.007417	1.008637	1.009853	1.011065	1.012272
$\frac{1}{2}$ year	1.014889	1,017349	1.019804	1.022252	1.024695

PROBLEM III.

To find the preſent Value of an Annuity to continue a given Time, at a given Rate per Cent.

Rule. Multiply the amount of 1l. for a year, as often into itſelf as there are years, leſs 1, (or which is the ſame, involve it to the power denoted by the time); by this reſult divide 1, and ſubtract the quotient from 1; divide the remainder by the intereſt of 1l. for a year; then multiply this laſt quotient by the annuity, and the product will be the preſent value.

Examp. What is the preſent worth of an annuity of 40l. to continue five years, diſcounting at 5 per cent. per annum, compound intereſt. Here 1.05 involved to the 5 power = 1.27628, by which dividing 1, there is .78353, which ſubtracted from 1, leaves, .21647; and this divided by .05, gives 4.3294, which multiplied by 40, we have 173.176l. = 173l. 3s. 6$\frac{1}{4}$d. *fere*, = the preſent worth.

N. B. If the payments are half yearly or quarterly, take the time and the amount, and intereſt of 1l. as directed in the laſt articles, and the rule will hold good.

Corollory. The preſent value of an annuity for a given term, but not to commence till certain years hence, is had by finding, firſt, the preſent value of the annuity for the given term, and then the preſent worth of that ſum according to the number of years which is to elapſe before the annuity commences.

PROBLEM IV.

An Annuity, the Amount thereof for a certain Term; and the Rate of Intereſt being given. To find the Time.

Rule. Multiply the amount by the intereſt of 1l. for a year, and divide the product by the annuity. To the quotient add 1, then divide the logarithm of this ſum, by the logarithm of the amount of 1l. for a year, and the quotient will be the time required.

Examp. In what time will an annuity of 100l. amount to 315l. 5s. 0d. at 5 per cent. per annum compound intereſt. Here $315.25 \times .05 = 15.7625$, which divided by 100, the quotient is .157625, to which adding 1, the ſum is 1.157625; and the logarithm thereof is .0635679. Alſo the logarithm of 1.05 is .0211893; by which, dividing .0635679, the quotient is 3, the true number of years required.

Scholium. This method, as well as that in the following Problem, always ſuppoſes that the perſon is intitled to a proportional part of the next annual payment, anſwerable to the parts of a year, which may happen to be over and above the complete years, diſcount being allowed for the remainder of the year.

PROBLEM V.

An Annuity, the preſent worth thereof, and the Rate of Intereſt being given to find the Time.

Rule. Multiply the preſent worth by the Intereſt of 1 l. for a year, and ſubtract the product from the annuity; take the logarithm of the remainder, and ſubtract it from the logarithm of the annuity; and divide this remainder by the logarithm of the amount of 1l. for a year, and the quotient will be the time required.

It will be needleſs to give an example, as thoſe who underſtand the laſt Problem will find no difficulty in this.

PROBLEM VI.

To find the Value of a Freehold Eſtate, or of an Annuity to continue for ever, at Compound Intereſt.

Rule. Divide 100l. by the rate of intereſt per cent. or, which is the ſame, divide 1l. by the intereſt of 1l. for a year; and the quotient will be the value of an annuity of 1l. to continue for ever; or of an eſtate, whoſe annual rent is 1l. or, in other terms, it will be the number of years purchaſe which ſuch annuity or eſtate is worth; and that being multiplied by the annuity or annual rent, will give the whole value required.

Examp. What is the value of an annuity of 100l. to continue for ever at 5 per cent. compound intereſt? Here 1l. divided by .05; or 100l. divided by 5, gives a quotient of 25, the number of years purchaſe; and this multiplied by 100l. gives 2500l. the value required.

N. B. The number of years purchaſe of an eſtate, or of an annuity to continue for ever, (which in this caſe is 25) is called the perpetuity thereof.

PROBLEM VII.

Given the amount or preſent Value of an Annuity or certain Annual Payments, to determine therefrom what would be the Amount or preſent Value, provided the ſame were paid in equal half yearly or quarterly payments, or in equal portions, at any other intervals, whereof one is an aliquot part of a year.

Rule. Multiply the given amount, or preſent value, by the intereſt of 1£. for a year, and divide the Product by twice the intereſt of 1l. for half a year, or four times the intereſt of 1l. for a quarter of a year, (or, in general, by *m* times the intereſt of 1l. for $\frac{1}{m}^{th}$ of a year) and the quotient in each caſe will be the amount or preſent worth required.

ANNUITIES.

To prove the truth of this rule, put $m =$ to any aliquot part of a year, or the interval between each payment, and $n =$ number of years. Then $1+\overline{1+r}^{\frac{1}{m}}+\overline{1+r}^{\frac{2}{m}}+\overline{1+r}^{\frac{3}{m}}+\overline{1+r}^{\frac{4}{m}}$, &c. to $\overline{1+r}^{\frac{nm-1}{m}} =$ the amount of an annuity of m pounds for n years

$$= \frac{\overline{1+r}^{\frac{1}{m}}\times\overline{1+r}^{\frac{nm-1}{m}}-1}{\overline{1+r}^{\frac{1}{m}}-1} = \frac{\overline{1+r}^{n}-1}{\overline{1+r}^{\frac{1}{m}}-1}.$$

But the numerator or dividend, $(\overline{1+r}^{n}-1)$ is the ſame, let m be what it will; and when $m = 1$, then the diviſor, $(\overline{1+r}^{\frac{1}{m}}-1)$ is $= r$, the intereſt of 1 l. for a year; and conſequently the yearly amount, multiplied by r, will always give the dividend.

Alſo the diviſor, in general, is equal to the intereſt of 1l. for the interval denoted by $\frac{1}{m}$; but when each payment is the $\frac{1}{m}$ of 1l. then the diviſor, in order to give the correct amount, is $m\times\overline{\overline{1+r}^{\frac{1}{m}}-1}$, or m times the intereſt of 1l. for the interval $\frac{1}{m}$, by which the dividend, when found as above, is to be divided.

Again $\frac{1}{\overline{1+r}|^{\frac{1}{m}}}+\frac{1}{\overline{1+r}|^{\frac{2}{m}}}+\frac{1}{\overline{1+r}^{\frac{3}{m}}}$ &c. to $\frac{1}{\overline{1+r}^{\frac{nm}{m}}}$ or $\frac{1}{\overline{1+r}^{n}}$, $=$ the preſent value of an annuity of m pounds for n years $=$

$$\frac{\frac{1}{\overline{1+r}^{\frac{2}{m}}}\times\frac{1}{\overline{1+r}^{n}}-\frac{1}{\overline{1+r}^{\frac{2}{m}}}}{\frac{1}{\overline{1+r}^{\frac{2}{m}}}-\frac{1}{\overline{1+r}^{\frac{1}{m}}}}=\frac{\frac{1}{\overline{1+r}^{n}}-1}{1-\frac{1}{\overline{1+r}^{\frac{1}{m}}}}.$$

But both the numerator and denominator, are negative quantities; and, therefore, the aſſirmative expreſſion is,

$$\frac{1-\frac{1}{\overline{1+r}^{n}}}{\overline{1+r}|^{\frac{1}{m}}-1}.$$

And the numerator, or dividend, being unaffected with m, remaineth the ſame, let m be what it will. Alſo, the diviſor being the ſame as in the former caſe, the ſame concluſions obtain here.

Cor. I. The amount of an annuity of 1l. for n years (ſuppoſing the firſt payment not due till a year hence) is equal to the intereſt of 1l. for n years divided by the intereſt of 1l. for a year.

Cor. II. The preſent value of ſuch an annuity for n years is equal to the diſcount of 1l. for n years divided by the ſaid diviſor, or intereſt of 1l. for a year.

Cor. III. The intereſt of 1 l. for n years, divided by m times the intereſt of 1l. for $\frac{1}{m}$ of a year, is equal to the amount of 1l. Annuity for n years, when the ſame is paid in equal portions at every $\frac{1}{m}$ of a year.

Cor. IV. Alſo if the diſcount of 1l. due n years hence, be divided by the ſame diviſor, the quotient will be the preſent value of ſuch annuity on the ſame terms.

N. B. The intereſt of 1 £. for any aliquot part of a year is found thus: Divide the logarithm of the amount of 1 £. for a year, at the given rate of intereſt, by the number denoting the aliquot part, and the quotient will be the logarithm of the amount of 1 £. for ſuch part of a year, then the number anſwerable thereto, is the amount itſelf. Alſo the amount, leſs 1, is the intereſt.

With regard to the foregoing rule, the time is ſuppoſed to be years complete, but if otherwiſe, the concluſion can ſcarce ever err the hundredth part of a year's purchaſe, and therefore it may juſtly be applied in all caſes of life annuities, the ſubject not being capable of greater accuracy. The caſes, however, which reſpect the two laſt corrollories, do not come under ſo cloſe a reſtriction; for when the payments are made at every $\frac{1}{m}^{th}$ part of a year, the time in them is limitable only to ſuch part of a year, or a complete number of payments, viz. it may be any fraction of a year expreſſed by $\frac{1}{m}$, $\frac{2}{m}$, $\frac{3}{m}$, $\frac{4}{m}$, &c. to $\frac{m-1}{m}$.

SCHOLIUM I.

Another ſtill ſhorter method may be uſed for reducing the value of yearly to that of half yearly payments, viz. Multiply half the amount or preſent value of the yearly payments by the intereſt of 1l. for half a year. Add the product to the ſaid amount, or preſent value, and it will be the anſwer required. Alſo, If half the half yearly value thus found be multiplied by the intereſt of 1l. for a quarter of a year, and the product be added to the half yearly value, it will give the quarterly value.

The former method, however, is preferable on account of its generality, and being in all caſes well adapted to practice.

SCHOLIUM II.

If the given time be ſuch as to fall between two payments, the amount or preſent value muſt be found for the time comprehending the complete payments, let the time between each be what it may; then, when the amount is to be found, the preſent worth of ſuch proportional part of the next payment as is anſwerable to the time which is over and above the laſt payment, muſt be found, by diſcounting for the interval which the given time falls ſhort of the next payment. Alſo the amount of the former amount muſt be ſought for the interval which is over and above the laſt payment; ſo will the ſum of this amount and the laſt mentioned preſent worth, be the true amount required. But if the preſent value is required, then the preſent worth of the ſaid proportional part of the next payment muſt be found, (by diſcounting for the whole given time) and added to the preſent value of the complete payments, and the ſum will be the anſwer required.

N. B. I believe theſe matters have not been ſo fully handled before.

SCHOLIUM III.

Where compound intereſt is concerned, all the caſes will be beſt wrought by logarithms, as that method ſaves a deal of trouble; multiplication and diviſion being thereby performed by the addition and ſubtraction of only two numbers, and involution by a ſhort multiplication, as will be ſhewn under the proper head. But as this work may fall into the hands of thoſe who are not well acquainted with the nature of them, or who, perhaps, have not accurate tables thereof, I ſhall add two ſmall tables, which in moſt caſes will very well ſupply the want of them.

TABLE I.

THE AMOUNT OF AN ANNUITY OF ONE POUND.

Y.	3 per Cent.	3½ per Cent.	4 per Cent.	4½ per Cent.	5 per Cent.

USE OF THE TABLES.

By Table the 1ſt, Problem the 2d may be reſolved; for the tabular number anſwering to the number of years and rate per cent. multiplied by the annuity will give the amount. In the example, the given number of years are three, and the intereſt 5 per cent. The tabular number is 3.1525, which multiplied by 50, the annuity, the product is 157.625 £. the ſame as before.

By Table 2d, the 3d Problem is reſolved. Thus the tabular number anſwering to five years and 5 per cent. is 4.329477 which multiplied by 40, the annuity, gives 173.179 £. nearly the ſame as before.

Alſo by means of table I. the amount of any ſum of money for a given number of years, at compound intereſt, according to any of the rates per cent. may be found by multiplying the given ſum by the difference between the tabular number for the given number of years, and the next greater tabular number in the ſame column.

Examp. Let it be required to find the amount of 50 £. at the expiration of ſeven years, at five per cent. per annum, compound intereſt. Here the tabular number for ſeven years at five per cent. is 8.142008, and the next greater (or that for eight years) is 9.549109. Their difference is 1.407101, which multiplied by 50=70.35505 £.=70 l. 7s. 1¼d. *fere*, the amount required.

In like manner the preſent worth of a ſum of money due certain years hence, may be found by Table 2d, by multiplying the given ſum by the difference between the tabular number anſwering to the given number of years, and the next leſs tabular number in the ſame column.

Examp. What is the preſent worth of 120 £. due nine years hence, at 5 per cent. per annum compound intereſt? Here the tabular number againſt nine years at 5 per cent. is 7.107822; and the next leſs (or that for eight years) is 6.463213; their difference is .644609; and this multiplied by 120=77.35308 £.=77 l. 7s. 0¼d. *fere*, the value required.

Alſo if the amount or preſent worth of an annuity be given and it be required to find the time, it will be found by dividing the ſame by the annuity, and looking for the quotient, or the next leſs number (in the table of amounts or preſent worths) under the proper rate per cent. For the number of years in the firſt column will be the time required. But if it is required to determine the time to parts of a year, take from table 2d, the preſent worth of 1 l. due one year hence, and add the ſame to the next leſs number. Then take the logarithm thereof, and ſubtract the ſame from the ſum of the logarithms of the ſaid next leſs number, and the quotient above mentioned. Divide the remainder by the logarithm of the amount of 1l. for a year, and the quotient will be the time required.

Likewiſe, if it be required to find the amount or preſent value of an annuity for a time greater than is ſpecified in the table, divide the propoſed time into two periods, and take the amount or preſent value for one period, and find the amount or preſent value of that ſum for the remaining period; alſo find the amount or preſent value of the annuity for the remaining time, then add the two amounts or preſent values together, and the ſum will be the anſwer. If the time be above 90 years, then divide it into 3 or more parts, and proceed in the ſame way to find the value of each part, and take the ſum of the whole.

With reſpect to the firſt part of annuities, or annuities certain, I have now given all that appears uſeful, according to the moſt correct methods; but in matters of ſcience, truth is more firmly eſtabliſhed, when the artiſt not only ſhews what is right, but alſo points out what is wrong; and therefore I cannot cloſe the chapter without noticing a certain inaccuracy of Doctor Price, relative to half yearly and quarterly payments. In the laſt edition of his Annuities, Vol. 2. Page 222, he ſays, that "the amount at any "given yearly intereſt of any given Annuity, payable half yearly, is "the ſame with the amount of half that Annuity at half the inter-"eſt, and payable a double number of times." This, however, is certainly wrong, and the amount in this manner will exceed the truth: for it ſhould not be half the intereſt; but, if in yearly payments, the intereſt of 1l. per annum is uſed, then in half yearly payments, not half of that, but the intereſt of 1l. for half a year, according to the method of compound intereſt, ſhould be taken, which is leſs than half the yearly intereſt of 1l. and for the ſame reaſon, the theorems, which the Doctor has given in his third additional eſſay, at the end of the ſaid volume, (pages 33, 34, 38, &c.) which is alſo publiſhed in the Philoſophical Tranſactions, Vol. 66. Part I. are incorrect; notwithſtanding the Doctor's obſervation, that he has no where ſeen theſe matters ſtated with accuracy; and therefore he thought his attempt might be of uſe.

I have not mentioned this with a view to depreciate Dr. Price, as he is certainly deſerving of praiſe for the pains which he has beſtowed on Annuity calculations, but (as the Doctor has cenſured the true method) that the young ſtudient may be guided right. To prove that his method is erroneous, nothing further is neceſſary than to find the amount of each payment by itſelf, according to the given yearly intereſt, and alſo to compute the value on his hypotheſis, and it will be found that this latter will exceed the ſum of the former, and is therefore manifeſtly wrong. By the ſame mode it will be found that the *preſent value* of half yearly or quarterly payments, on his hypotheſis is too ſmall.

CHAP. II.

ANNUITIES CONTINGENT.

THE calculations for life annuities depend ſolely on the doctrine of probabilities, which tho' to ſome may appear without the limits of human inveſtigation, yet the theory has been ſo far eſtabliſhed by practice, as to render it indiſputable.

It is by all allowed that the Supreme Being cannot be impreſſed with an idea of probability, ſince all things that are or ſhall be, are alike comprehended by Him, who is the Alpha and Omega. With Him, therefore, all things are certain, and all are directed by His infinite wiſdom to their proper ends, ſo that the notion of contingency, when applied to the Creator and Lord of the univerſe, is wholly abſurd. But to us who are ſhut up to the future, and can only form our judgments according to the preſent appearance of things, the idea of probability forces itſelf on our intellects. Thus we cannot but expect an approaching ſtorm, when we ſee the clouds black with tempeſt; and on the contrary, when there is a ſettled ſerenity in the atmoſphere, we have the ſtrongeſt expectations of a continuation of fair weather. In like manner, a phyſician forms his judgment from the ſeveral indications of a diſorder; and, in general, the happening of a future event appears more or leſs probable, according as there are more or fewer marks of its approach.

Wherefore, without preſuming on the Divine order, we may certainly form our eſtimations on lives, if our concluſions are fairly deduced from obſervation, and the more eſpecially ſo, as ſociety and various occurrences in life often render them neceſſary. Thus a perſon has as an undoubted a right to ſell a life eſtate, as any other, and this calls for a proper and equitable valuation; for who would give as much for a life eſtate on an age of 60, as for one on an age of 20 or 30, provided both the parties were equally healthful? To determine upon an average the proper values of each, with other things of the like nature, is the buſineſs of which I ſhall now treat. It appeared requiſite to make theſe obſervations, becauſe calculations of this ſort have been frequently ridiculed, from a want of giving the ſubject a right thought.

The calculations here given are formed from compariſons on the bills of mortality for all ages, the only method that can with propriety be depended on. Uſeful tables are given to facilitate the computations; but, before we proceed, it will be proper to give the following

DEFINITIONS:

I. The probability of life is greater or leſs according as there appears more or fewer chances for a perſon's living or dying at any given ſtage of life, and is denoted by a fraction, whoſe numerator is the chances of living, and denominator the ſum of the chances both of living and dying. Thus, if it be obſerved that out of 500 perſons of one age, only 380 of them are in being at the end of 2 years, in that caſe the probability of any one's ſurviving 2 years, is $\frac{380}{380+120}=\frac{380}{500}=\frac{38}{50}=\frac{19}{25}$, and the odds in that caſe are 19 to 6 that a perſon of that particular age ſhall be living two years hence. The probability of dying is a like fraction, whoſe numerator is the chances of dying. In the preſent caſe the probability of dying, is $\frac{120}{500}=\frac{6}{25}$; and the odds are 19 to 6 that the perſon does not die in 2 years. —The ſum of the probabilities of living and dying is $=1$, which is expreſſive of a certainty.

II. The extremity of life is that period beyond which there is no probability of ſurviving. In the Northampton tables this period is 97 years.

III. The complement of life, is the number of years which any perſon's age wants of the full extremity. Thus the complement of an age of 90 is 7.

IV. The expectation of life is the number of years which is due to the life of a perſon of a certain age upon an equality of chance, or it is the number of years purchaſe, which an annuity for life, ſecured upon land without intereſt, is worth in ready money.

This in ſingle lives is always equal to the ſum of all the probabilities of ſurviving each moment to the extremity of life.

V. The number of years purchaſe, in annuities, eſtates, &c. at any rate of intereſt, is that number which, if multiplied by the annuity or annual rent, is equal to the preſent value thereof, according to ſuch rate of intereſt, or it is the preſent value of an annuity or annual rent of 1l. according to the given rate of intereſt.

VI. Reverſion of a life annuity, is where two or more lives are in joint poſſeſſion, and the expectation depends upon the probability of one particular life's ſurviving the reſt.

USE OF THE TABLES.

The 1ſt and 2d Tables exhibit the probabilities of life at all ages in London and Northampton, according to the bills of mortality; that for London I have taken from the ſelect exerciſes of the late engenious Mr. Thomas Simpſon, F. R. S. together with ſuch of the following tables as are dependent thereon, it being proved from recent obſervations that they are ſtill the moſt correct of any extant.

The other with the reſt of the tables for Northampton are extracted from the laſt treatiſe of Dr. Price, a work in itſelf truly valuable, notwithſtanding the fault which I remarked at the concluſion of the laſt chapter, relative to half yearly and quarterly payments. I was the more induced to give thoſe tables, becauſe Northampton, though a pretty large town, is healthfully ſituated, and conſequently they may be taken as a ſtandard for country lives.

Of the 1ſt and 2d Tables, the 1ſt column is the age, the 2d the number of perſons living at any age, and the third column is the annual decrement, or the number of deaths happening each year. Thus in Northampton Table, out of 11650 births, there are but 4310 perſons who ſurvive the age of 31, and only one perſon who attains the age of 96. In the London Table, out of 1000 perſons born, there are but 400 living at the age of 12 and only 25 arrive at the age of 79. Hence according to the London Table, the probability of living to the age of 40 is $\frac{400}{1000}$ or $\frac{4}{10}$, and the probability of the contray is $\frac{1000-400}{1000}, = \frac{600}{1000} = \frac{6}{10}$, and conſequently the odds that a new born child does not attain to that age is 6 to 4. Again in the London Table out of 280 perſons of 33 years of age, but 141 arrive at the age of 53; the probality is $\frac{41}{80}$, or $\frac{1}{2}$ nearly, ſo that is an equal wager that a perſon of good health aged 33 ſhall live 20 years. Theſe things promiſed I ſhall proceed to the ſolution of problems relative to lives, &c.

PROBLEM I.

To find the period or term of years which a perſon of a given age has any aſſigned probability of ſurviving. Rule take from the table the number of perſons anſwerable to the given age, multiply the ſame by the given probability and ſeek the reſult in the 2d column of the table, and againſt it in the firſt column is the age limiting the term of years required.

EXAMP. If the probability that a perſon aged 40 ſhall live a certain term of years is $\frac{3}{4}$, or which is the ſame, if the odds in his favour are juſt 3 to 1; required the number of years? Here (by the Northampton Table) the number of perſons at that age is 3635; and $3635 \times \frac{3}{4} = \frac{10905}{4} = 2726\frac{1}{4}$. I look in the table for 2726, and find it falls between the age of 51 and 52. And by taking a proportional part according to the differences, the exact age is 51.606 years? Hence the required term is 11.606 years.

SCHOL. If the term expire before the 8th or 9th year of age, the decrements of life being ſo exceeding irregular within that period, the time over and above the complete years cannot be determined accurately, for the proportioning of the differences will not hold good.

PROBLEM II.

To find what is the Probability that any Number of Perſons of given Ages, ſhall all ſurvive a certain Term of Years.

RULE, Find (from the table) as has been before illuſtrated, the probability of each perſon's ſurviving the term; then the product of all theſe probabilities will be the probability ſought.

EXAMP. What is the probability that three inhabitants of London, whoſe Ages are 40, 50, 60, reſpectively, ſhall be all living 10 years hence?

Firſt, that one of the age of 40 ſhall live 10 years, the probability is $\frac{159}{229}$, that one of 50 lives 10 years, is $\frac{102}{159}$, and that one of 60 ſurvives that term, is $\frac{54}{102}$. The product of theſe is $\frac{159 \times 102 \times 54}{229 \times 159 \times 102} = \frac{54}{229} = \frac{3}{13}$ nearly; and conſequently the odds are 10 to 3 that they are not all living 10 years hence.

SCHOL. If it is required to know the probability of certain perſon's being alive, and alſo of other's being dead at the end of any given term. Then the reſpective probabilities of living and dying muſt be multiplied together, and the product will be the probability ſought.

PROBLEM III.

If a Perſon of a given Age has a certain Sum of Money due at ſo many Years hence, provided he lives ſo long, it is required to determine the preſent Value thereof, or what it is worth in Caſe it ſhould be ſold.

RULE. Find the preſent worth of the ſum for the given number of years, as though the time were certain; then multiply the ſame by the probability of the perſon's living till that time, and the product will be the anſwer.

EXAMP. A perſon aged 70 years is to receive 10l. if he lives till 75. What is the preſent value thereof according to the London bills of mortality, ſuppoſing intereſt to be at 4 per cent. per annum? Here the preſent value of 10l. due 5 years hence is 8.2193, and the probability of one of 70 years old living 5 years is $\frac{36}{54} = \frac{2}{3}$; and $8.2193 \times \frac{2}{3} = 5.4795$l. = 5l. 9s. 7d. the the anſwer.

SCHOL. If ſeveral ſums of money were due, in like manner at different periods, the preſent value of the whole would be obtained by finding the value of each ſeparate ſum, and adding the whole together. By a ſimilar mode of proceeding the value of an annuity upon any ſingle life may be found, as alſo upon any number of joint lives, by multiplying the probability of their all continuing in being till the end of each diſtinct year taken ſeparately, and during the complement of the oldeſt life, by the preſent value of 1l. diſcounted from the expiration of each ſuch year, according to the given rate of intereſt, then the ſum of the whole will give the value ſought. But in practice, the proceeding in this way, year by year, to the utmoſt period of life would be intolerable labour, and on this account it is that I have added tables whereby this and other caſes of ſtill greater difficulty may be ſolved with facility and diſpatch. I ſhall not, therefore, inſiſt further on the theory from the doctrines of chance, but proceed to the direct application of the tables in the moſt uſeful caſes, which as it is a ſubject of general utility, wherein even the nation itſelf is concerned; I am perſuaded, that the extending of it rather beyond the bounds which we had preſcribed will be highly agreeable to the reader. It is our wiſh and aim to be ſufficiently copious on every intereſting matter, and to expunge as much as poſſible whatever appears to be not ſo.

PROBLEM IV.

To find the Value of an Annuity during the Life of a Perſon of a given Age, at any propoſed Rate of Intereſt.

RULE. In Table VI. look for the age in the 1ſt column, and againſt it, under the proper intereſt, is the number of years purchaſe, or, which is the ſame, the preſent value of an annuity of 1l. during ſuch life. Multiply this by the annuity, and the product is the anſwer.

EXAMP. Suppoſe the age be 50, the rate of intereſt 3 per cent. and the annuity 20l. Here againſt age 50, and under 3 per cent. we have 11.6, according to the London Bills, and 12.69, as by the bills of Northampton, which, multiplied by 20, there is 232l. for the value of a London life, and 253l. or 253l. 16s. for the value of a Northampton life.

PROBLEM V.

To determine the Value of an Annuity granted for a given Term of Years, upon the Contingency of its ceaſing on the Failing of a propoſed Life, before the Expiration of the ſaid given Term.

Rule. Take the value of the whole life from the table. Alſo take the value of another life whoſe age is greater than the former by the given term of years; and find the preſent value thereof by diſcounting at the given rate of intereſt for the ſaid given term: then take ſuch part of that value as is denoted by the probability of the perſon's ſurviving the ſaid term; ſubtract the ſame from the value of the whole life, and the remainder will be the anſwer.

Examp. Let the age be 10, the term of years 15, and the rate of intereſt 5 per cent. per annum. Here the value of an age of 10 by the London table is 14.3; the value of an age of 25 is 12.3; and the preſent value of 1l. to be received at the end of 15 years is .481; then $12.3 \times .481 = 5.9$ = preſent value of an annuity to be granted to an age of 25, fifteen years hence. Alſo the probability that one of the age of 10 is ſurviving 15 years, hence is $\frac{333}{410} = \frac{100}{123}$ nearly, and $5.9 \times \frac{100}{123} = \frac{590}{123}$ 4.8 = the value of a life annuity to be granted 15 years hence upon an age of 25, on the contingency that one, whoſe preſent age is 10, will be then ſurviving. And $14.3 - 4.8 = 9.5$, = the number of years purchaſe which an annuity on propoſed conditions is worth.

Problem VI.

To find the Value of an Annuity for Life, to commence after a given Term of Years, provided a Perſon of a certain Age ſhall Live till then.

Rule. Find the value of an annuity for an age greater by the given term than the propoſed age, and multiply the ſame by the probability of the perſon's ſurviving the ſaid term; then find the preſent worth thereof, diſcounting for the given term of years according to the propoſed rate of intereſt, and it will be the value ſought.

Examp. What is the value of an annuity for the life of a perſon of 10 years of age, but not to commence till 15 years hence, ſuppoſing the intereſt 5 per cent. per annum. Here the value of a life of 25 years is (by the London Tables) 12.3 the probability of an age of 10 living 15 years, is $\frac{333}{410}$; this multiplied by 12.3, the product is $\frac{12.3 \times 333}{410} = \frac{12.3 \times 999}{1230.} = \frac{999}{100} = 9.99$ or 10, nearly; the preſent value of 1l. due 15 years hence = .481, and $.481 \times 10 = 4.81$ = the number of years purchaſe of the propoſed annuity.

Schol. If the value thus found be ſubtracted from the value of the life of 10 years, the remainder will be the value of an annuity granted, during the 15 years, on proviſo that ſuch life ſhall continue ſo long, but to ceaſe on the failure thereof, if the ſame ſhall happen before the expiration of that term. This will hold in all ſimilar caſes.

Problem VII.

To find the Value of an Annuity during the Joint Lives of two Perſons of given Ages.

Rule. In table VII. column 1, look for the age of the younger (or that neareſt to it) and find in column 2d the age of the elder, againſt which, under the given rate of intereſt, you will have the number of years purchaſe.

Examp. Let the ages be 25 and 30 reſpectively, and the rate of intereſt 3 per cent. Here it is manifeſt at ſight that the value according to the London bills 11.3 years purchaſe, and according to the Northampton bills 12 97 years purchaſe.

Schol. If the ages had been 25 and 33, the value muſt have been determined by taking proportional parts. Thus, for London, the value for 25 and 30 is as before 11.3, and for 25 and 35 it is 10.7, the decrement is .6; then as 5 (or 35—30) : .6 :: 3 (or 33—30) : .3; which ſubtracted from 11.3, the remainder is 11, for the value ſought.

Again, if the ages were 28 and 33. Here, by the foregoing, the value for the ages 25 and 33 is 11. and by proceeding in the ſame manner the value for 30 and 33 will be found = 10.5; the difference is .5. And as 5 (or 30—25) : .5 :: 3 (or 28—25) : .3 which ſubtracted from 11. the remainder is 10.7 = the number of years purchaſe for the joint lives of two perſons, whoſe ages are 28 and 33. And thus by proportioning the differences may the value for any other ages within the limits of the table be determined.

Problem VIII.

To find the Value of an Annuity granted during the longeſt of Two Lives.

Rule. Find the value of each life ſeparately, and alſo the value of the joint lives; then, from the ſum of the two ſingle lives, ſubtract the joint life, and the remainder will be the number of years purchaſe for an annuity granted during the life of the longer liver of two perſons.

Examp. Let the given ages be 15 and 40 years, and the rate of intereſt 4 per cent. Here, the value of a life, whoſe age is 15 years, (by the London Tables) is 15.8; and of a life, whoſe age is 40 years, it is 11.5. Alſo the value of the joint lives is 9.4. Then $15.8 + 11.5 - 9.4 = 17.9$, the value required.

Problem IX.

To find the Value of an Annuity during the joint Lives of Three Perſons.

Rule. Find the value of the joint lives of any two, and find the age of a ſingle life, equivalent to that value. Then find the value of the joint lives of the remaining perſon, and a perſon whoſe age is the age of ſuch ſingle life, and it will be the anſwer ſought.

Examp. Let the ages be 20, 35, and 45, reſpectively; and intereſt at 4 per cent. Here take the value of the joint lives of any two, ſuppoſe 20 and 35, which, by the London Table, is 9.8; and the age, which anſwers to this in the table of ſingle lives is 52. Alſo the value of the joint lives, whoſe ages are 45 and 52, is 6.4 = the number of years purchaſe for an annuity, on the joint lives of three perſons, whoſe ages are as above ſpecified, and intereſt at 4 per cent.

Schol. If the value of the joint lives of four perſons is required; find the age anſwering to the value of any three; then in the table of joint lives, with the age ſo found, and the remaining age, take out the correſponding value, and it will be the anſwer ſought. If the value of the joint lives of five perſons is required, ſeek an age anſwerable to four, and proceed as above; and ſo on for any other number of lives.

Problem X.

To find the Value of an Annuity on the longeſt Life of three or more Perſons.

Rule. Find an age anſwerable to the value of the longeſt life of any two, which ſubſtitute in lieu of the two, and then find the value of the longeſt life of it and another, and it will be the value of the longeſt life among three lives. If there are four or more lives, ſubſtitute the age correſponding to this value in lieu of the three lives, and find the value of the longeſt life of this age, and the other remaining age, and it will be the value of the longeſt of four lives. Proceed in the ſame manner for five or more lives, regard being had to the rate of intereſt.

Having given Examples in the former Problems ſufficient to ſhew the uſe of the Tables, it will be unneceſſary to give more, the rules being plain and eaſy. I ſhall, however, add a few other Problems with proper directions, and then conclude the ſubject.

Problem XI.

To find the Value of an Annuity for as long as any two or three certain Perſons ſhall be alive.

Rule. From the ſum of the values of the joint lives of every two (viz. of AB; AC, and BC) ſubtract twice the value of the joint lives of the three, (viz. ABC) and the remainder will be the number of years purchaſe required.

Problem XII.

To find the Value of a Reverſion of an aſſigned Life after a given Term of Years.

Rule. From the value of the propoſed life ſubtract the value of an annuity for the given term of years, on the contingency of its ceaſing upon the extinction of the aforeſaid life (found by Prob. V.) and the remainder will be the anſwer.

Problem XIII.

To find the Value of the Reverſion of an Annuity for the Remainder of a given Term of Years, after an aſſigned Life.

Rule. From the value of an annuity certain for the given term, ſubtract the value of the annuity for the ſaid term, on the contingency of its ceaſing upon the failing of the propoſed life, and the remainder will be the value of the reverſion.

Problem XIV.

To find the Value of the Reverſion of one Life after another.

Rule. From the value of the life in expectation ſubtract the value of the two joint lives, and the remainder will be the value of the reverſion.

Problem XV.

To find the Value of the Reverſion of two Lives after one.

Rule. From the value of the longeſt of the three lives ſubtract the value of the life in poſſeſſion, and the remainder will be the value of the reverſion.

Problem XVI.

To find the Value of the Reverſion of one Life after Two Joint Lives.

Rule. From the value of the life in expectation, ſubtract the value of the three joint lives, and the remainder will be the anſwer.

Problem XVII.

To find the Value of the Reverſion of One Life after Two.

Rule. From the value of the three lives (found by Problem X.) ſubtract the value of the two lives in poſſeſſion; and the remainder will be the value of the reverſion.

Problem XVIII.

To find the Value of the Reverſion of Two Joint Lives after One.

Rule. From the value of the two joint lives in expectation, ſubtract the value of the three joint lives, and the remainder will be the value of the reverſion.

Problem XIX.

Two Perſons A & B have a Joint Annuity, which, after the Deceaſe of either of them, is to belong entirely to the Survivor for Life. To find the Value of the Right of each in that Annuity.

Rule. From the value of the life of A or B ſubtract half the value of the two joint lives, the remainder will be the value of the right of A or B accordingly.

Problem XX.

D, and his Heirs, as ſoon as any two of three joint Lives, A, B and C, become extinct, are to enter upon an Annuity, and to enjoy the ſame during the Life of the Survivor; required the preſent Value of the Expectation.

Rule. To the ſum of the ſingle lives A, B, and C, add thrice the value of the three joint lives, deducting therefrom twice the ſum of the values of each pair of joint lives; viz. of A and B; A and C, and B and C, and the remainder will be the anſwer.

Problem XXI.

A given Annuity after the Deceaſe of A, is to be divided equally between B and C, during their Joint Lives, and then is to go entirely to the Laſt Survivor for Life, it is required to find the Value of B's Expectation.

Rule. From the value of the reverſion of the life of B, after the life of A (found by Problem XIV) ſubtract half the value of the reverſion of the joint lives, B and C, after the life of A (found by Problem XVIII) and the remainder will be the value of B's expectation.

Problem XXII.

A B and C enjoy an Annuity equally amongſt them, which, upon the Deceaſe of any One, is to be equally enjoyed by the Survivors during their Joint Lives, and then the laſt Survivor is to have the Whole during his Life. To find the Value of the Right of any One, as A, in the ſaid Annuity.

Rule. From the value of the life of A, take half the ſum of the values of the joint lives, A and B, and the joint lives A and C, then to the remainder add $\frac{1}{3}$ of the value of the three joint lives, and the ſum will be the anſwer.

Problem XXIII.

A, enjoys an Annuity for Life, and is to have the Nomination of a Succeſſor, who is likewiſe to enjoy the Annuity for his Life: it is propoſed to find the Preſent Value of the Two ſucceſſive Lives.

Rule. Multiply the value of the life of A, by the value of the life put in at his deceaſe; divide the product by the perpetuity (found by Prob. VI. Chap. I.) and ſubtract the quotient from the ſum of the ſaid values, and the remainder will be the anſwer.

Problem XXIV.

To find the preſent Value of any Number of Lives in Succeſſion.

Rule. Multiply the value of each life, without regard to the order of ſucceſſion, by the intereſt of 1l. for a year, and ſubtract each product from unity; multiply all the remainders continually together, and ſubtract this product alſo from unity: then the laſt remainder multiplied by the perpetuity, will be the value of all the ſucceſſive lives.

Or, find (by table II.) the number of years anſwering to the value of each of the given lives; find alſo by *the ſame table*, the value of an annuity *certain*, for the whole of all theſe years added together, and it will be the anſwer ſought.

Problem XXV.

A given Sum of Money is to be received (as a Legacy) on the Deceaſe of B, who, is now of a given Age: what is the Value thereof in preſent Money?

Rule. Subtract the value of the life of B from the perpetuity. Then, by the rule of three, as the perpetuity is to the remainder, ſo is the propoſed ſum to its preſent value in money.

Problem XXVI.

A given Sum is to be received on the Extinction of the 1ſt. 2d. or 3d. of three aſſigned Lives, to find the preſent Value of the Expectation.

Rule. Find (by Prob. IX, X, or XI.) the value of an annuity granted upon the aſſigned lives, on condition of its ceaſing on the failing of the 1ſt, 2d, or 3d, of thoſe lives, according to the caſe propoſed; ſubtract the value from the perpetuity, and then proceed according to the proportion given in the laſt Problem.

Problem XXVII.

A given Sum is to be received as a Legacy, on the Deceaſe of B, in caſe that A is then extinct; it is required to find the preſent Value thereof, allowing for this Contingency.

Rule. From the value of an annuity, in land, *certain*, for as many years as are expreſſed by the complement of B's age, ſubtract the value of the oldeſt life. And then it will be, as the complement of the youngeſt life is to the remainder, ſo is the propoſed ſum, to its preſent value.

Schol. The tables in this chapter are founded on the principle of yearly payments, and withal ſuppoſe that nothing is to be paid to the heir, or executor, &c. of the annuitant for the time from the laſt yearly payment to his deceaſe, which, I believe, is frequently otherwiſe, and therefore to correct the value found by the tables ſo as to anſwer to any particular caſe, the following directions muſt be obſerved.

I. If it is required to have the yearly value ſuch as to include the lateſt moment of life; then find the preſent worth of an annuity of 1l. (by Table II.) for a number of years equal to twice the expectation found (by Table V.) divide the ſame by twice that number (or four times the expectation) and add the quotient to the value found in Table VI. and it will be the proper value agreeable to the above condition.

II. If the value according to half yearly or quarterly payments, on ſuch conſideration, is required, then, from the correct yearly value found as above, deduce the half yearly or quarterly values, by Problem VII. of Chapter I. and the reſult will be the anſwer.

III. If the half yearly or quarterly values are to be found on this ſuppoſition, that nothing is to be paid for the time between the laſt half yearly or quarterly payment and the death of the annuitant, then take the half or fourth (as the caſe ſhall be) of the correction found by the firſt direction for the yearly payments, and ſubtract the ſame from the value obtained by the 3d direction, and the remainder will be the anſwer.

Examp. Let the age be 36, ſthen the expectation is 25 nearly, the double thereof $=50$ years, and the value of an annuity of 1l. for that time at 4 per cent. is 21.4, which being divided by 100 makes .214, the correction to be added to 13.88, the value from the Northampton table of an age of 36; and conſequently the true value, ſuppoſing a proportional part of the annuity to be paid up to the time of the annuitant's death, is 14.09.

Alſo $\frac{14.09 \times .04}{.0396} = 14.23$, the value for half yearly payments; and $\frac{14.09 \times .04}{.0394} = 14.3$, the value for quarterly payments on the ſame principle.

But if nothing is to be allowed for the interval between the laſt half yearly or quarterly payment, and the time of death, then $14.23 - \frac{.214}{2}$ (or .107) $= 14.12$; and $14.3 -, \frac{.214}{4}$ (or .05) $= 14.25$, for the half yearly and quarterly values required; which methods of deducing the quarterly, and half yearly values are my own, and are much more correct than thoſe given by Doctor Price, in pages 38, 40, and 51 of his third additional Eſſay, not only on account of his making uſe of a falſe rate of intereſt, as I have before ſhewn, but upon other principles which are not ſtrictly true. I made choice of this example from his treatiſe, for the ſake of compariſon, and am well convinced, notwithſtanding the Doctor has continued his operations to three places of decimals, that ſome of his concluſions are incorrect in the *firſt* place.

Many of the foregoing Problems I have taken from the ſelect exerciſes of the late ingenious Thomas Simpſon, F. R. S. A work both ſcarce and valuable. More might have been added, though there are but few caſes, if any, that will occur in practice, that are not to be met with here, which cannot be announced of any other Dictionary of Arts and Sciences.

Indeed, in every other publication of this kind, the doctrine of Annuities has been paſſed over in a very curſory way, and therefore this Syſtem being at once full and compendious, as well as replete with uſeful improvements, will I hope by agreeable to the numerous Patronizers of this Work.

I think it proper alſo to apprize the Subſcribers, Authors, and literary Contributors to this Publication, that I am engaged by Mr. Cooke to write the Syſtem of Arithmetic, *and as I propoſe to introduce a variety of new matter, not to be met with in productions of a ſimilar kind, I flatter myſelf it will meet the general approbation of the public, and add to the eſtimation with which this work is favoured.*

R. MOODY.

Excise Office, Broad-Street.

Annuities for lives have generally been granted either upon ſeparate lives, or upon lots of lives, which in France are called tontines, from the name of their inventor.

When annuities are granted upon ſeparate lives, the death of every individual annuitant diſburthens the public revenue ſo far as it was affected by his annuity.

When annuities are granted upon tontines, the liberation of the public revenue does not commence till the death of all the annuitants comprehended in one lot, which may ſometimes conſiſt of twenty or thirty perſons, of whom the ſurvivors ſucceed to the annuities of all thoſe who die before them; the laſt ſurvivor ſucceeding to the annuities of the whole lot. Therefore upon the ſame revenue more money can be raiſed by tontines than by annuities for ſeparate lives.

An annuity, with a right of ſurvivorſhip, is really worth more than an equal annuity for a ſeparate life, and from the confidence which every man naturally has in his own good fortune, the principle upon which is founded the ſucceſs of all lotteries; ſuch an annuity generally ſells for ſomething more than it is worth.

The expedient which will raiſe moſt money, is almoſt always preferred to that which is likely to bring about in the ſpeedieſt manner the liberation of the public revenue.

In France a much greater proportion of the public debts conſiſts in annuities for lives than in England; for according to a memoir preſented by the parliament of Bourdeaux to the king in 1764, the whole public debt of France is eſtimated at twenty-four hundred millions of livres; of which the capital, for which annuities for lives had been granted, is ſuppoſed to amount to three hundred millions, the eighth-part of the whole public debt. The annuities themſelves are computed to amount to thirty millions a-year, the fourth part of one hundred and twenty millions, the ſuppoſed intereſt of that whole debt.

It is not the different degrees of anxiety in the two governments of France and England for the liberation of the public revenue, which occaſions this difference in their reſpective modes of borrowing; it ariſes altogether from the different views and intereſts of the lenders.

In Great Britain, the ſeat of government being in the greateſt mercantile city in the world, the merchants are generally the people who advance money to government. Yet, by this advance, they do not diminiſh; but are certain to increaſe their capitals; for unleſs they expected to ſell with ſome profit their ſhare in the ſubſcription for a new loan, they would not ſubſcribe.

But if they were to purchaſe annuities for lives only, whether their own or thoſe of other people, they would not always be ſo likely to ſell them with a profit, which perpetual annuities are always ſure to bring.

Annuities upon their own lives they would always ſell with loſs; becauſe no man will give for an annuity upon the life of another, whoſe age and ſtate are nearly the ſame with his own, the ſame price which he would give for one upon his own. An annuity upon the life of a third perſon, is, no doubt, of equal value to the buyer and the ſeller; but its real value begins to diminiſh from the moment it is granted, and continues to do ſo as long as it ſubſiſts. Therefore it can never make ſo convenient a transferable ſtock, as a perpetual annuity, of which the real value may be ſuppoſed always the ſame.

In France, the ſeat of government not being in a great mercantile city, merchants do not make ſo great a proportion of the people who advance money to government. The perſons concerned in the finances, are the farmers general, who receive the taxes which are not in farm; and the court bankers, make the greater part of thoſe who advance their money in all public exigencies. Thoſe people are generally men of mean birth, but of great wealth, and frequently of great pride. They are too proud to marry their equals, and women of quality diſdain to marry them. They frequently reſolve, therefore, to live bachelors, and having neither any families of their own, nor much regard for thoſe of their relations, whom they are not always very fond of acknowledging, they deſire only to live in ſplendor during their own time, and are not unwilling that their fortune ſhould end with themſelves. The number of rich people, beſides, who are either averſe to marry, or whoſe condition of life renders it either improper or inconvenient for them to do ſo, is much greater in France than in England. To ſuch people, who have little or no care for poſterity, nothing can be more convenient than to exchange their capital for a revenue, which is to laſt during life, which is as long as they wiſh it to do.

ANNUITY of Tiends, in the ancient Scots law, was a certain proportion of the tiends of erected benefices, formerly payable to the crown.

ANNULAR, in a general ſenſe, denotes ſomething in the form of a ring. It is alſo a peculiar denomination of the fourth or ring-finger. In anatomy, it denotes a ligament or cartilage that ſurrounds any particular bone, &c.

ANNULET, in architecture, ſignifies a ſmall ſquare member in the Doric capital, under the quarter-round.

Annulet implies alſo a narrow flat moulding, which is common to divers places of the columns. It is the ſame member which Vitruvius calls a *fillet*; Palladio, a *liſtil* or *cincture*; Scamozzi, and Mr. Brown, a *ſupercilium*, *liſt*, *tinea*, *eye-brow*, *ſquare*, *rabbit*.

Annulet, in heraldry, denotes a little circle, borne as a charge in coats-of-arms, as alſo added to them as a difference. Among the Romans it repreſented liberty and nobility. It alſo denotes ſtrength and eternity, by reaſon of its circular form.

When this figure is added as a difference, ſome authors aſſert, that it ſerves to remind the bearer to atchieve great actions.

ANNULLING, implies the cancelling or making void a deed, ſentence, or the like.

ANNUNCIADA, Annuntiada, or Annuntiata, an order of knighthood in Savoy, firſt inſtituted by Amadeus I. in the year 1409: the collar was of 15 links, interwoven one with another, in form of a true lover's knot, and the motto, F. E. R. T. ſignifying, *Fortitudo ejus Rhodum tenuit*. Amadeus VIII. gave the name Annunciada to this order, which was formerly known by that of the knot of love; changing at the ſame time the image of St. Maurice, patron of Savoy, which hung at the collar, for that of the Virgin Mary; and, inſtead of the motto above-mentioned ſubſtituting the words of the angel's ſalutation.

Annunciada is alſo the title of ſeveral religious orders, inſtituted in honour of the annunciation.

ANNUNCIATION, the tidings brought by the angel Gabriel to the Virgin Mary of the incarnation of Chriſt.

Annunciation is alſo a feſtival, kept by the church on the the 25th of March, in commemoration of theſe tidings. This feſtival is of very great antiquity; ſo that we may date its original from the ſeventh century.

Annunciation is likewiſe a title given by the Jews to part of the ceremony of the paſſover.

ANNUNCIATOR, the name of an officer in the church of Conſtantinople, whoſe buſineſs is to inform the people of the feſtivals that are to be celebrated.

ANOCHUS, in medicine, implies any thing which lodges in the ſtomach, and is incapable of digeſtion; as hair, wax, &c.

ANOCTORON, in eccleſiaſtical hiſtory, ſignifies a church built on the ſcite of a hill. In the modern acceptation of the word, it implies a religious houſe, or place of worſhip, built upon the ruins of a place of entertainment.

ANODUS, in chemiſtry, denotes a kind of putritory liquid, which is ſeparated by the kidneys, and neceſſarily contained in the body, as the ſuperfluities are carried off by urine and ſtool.

ANODYNE, among phyſicians, a term applied to medicines which eaſe pain, and procure ſleep. They are divided into three ſorts, viz. 1. Paregorics, or ſuch as aſſuage pain. 2. Hypnotics, or ſuch as relieve by procuring ſleep. 3. Narcotics, or ſuch as eaſe the patient by ſtupifying him.

Opiates and narcotics deſtroy ſenſation. Some hypnotics and paregorics, as nitre, camphor, &c. procure eaſe and ſleep by removing the offending cauſe. Camphor is ſaid to be the beſt anodyne in nervous caſes, and at the decline of fevers.

ANOINT, in the bible, has the following explanations; viz.

1. To pour oil upon, Gen. xxxi. 13. and xxviii. 18.

2. To conſecrate and ſet one apart to an office: anointing being generally practiced among the Jews on that occaſion to denote the perſon's being endued with the gifts and graces of the ſpirit. Exod. xxviii. 41.

3. To uſe ſpiritual means to get ſaving knowledge. Rev. iii. 18.

4. To ſmear or daub. John ix. 6. 11

5. One particularly deſigned and choſen by God, to be the king, prieſt, and prophet of his church; namely, Chriſt Jeſus, who was filled with the holy ghoſt in an extraordinary manner, and thereby conſecrated and authorized to be the Meſſiah. Pſal. ii. 2. xlv. 7. Acts vi. 27.

6. A king. Lam. iv. 20.

7. Touch not mine anointed. Pſal. cv. 15.

Hurt not the people conſecrated to myſelf, by the gift and graces of my ſpirit, nor thoſe eſpecially among them, to whom I familiarly reveal my mind and will that they may teach others.

Thou anointeſt my head with oil. Pſal. xiii. 5.

Thou beſtoweſt upon me the conſolation of thy ſpirit.

The ſpirit of illumination. Great knowledge in heavenly things. 1 John ii. 27.

ANOINTERS, were formerly a religious ſect in ſome parts of England, ſo called from the ceremony they uſed of anointing all perſons before they admitted them into their church. They founded their opinion of anointing upon the fifth of James, verſes 14 and 15.

ANOLE, in zoology, ſignifies a ſpecies of ſtriped lizard, natives of the Weſt Indies, that dig holes in the earth like rabbits; but keep watch all night like dogs, making a very diſcordant hoarſe noiſe, reſembling the barking of a ſmall terrier.

ANOLYMPIADES, in antiquity, was a name given by the Elians to thoſe Olympic games which had been celebrated under the direction of the Piſæans and Arcadians. The Elians claimed the ſole right of managing the Olympic games, in which they ſometimes met with competitors. The hundred and fourth Olympiad was celebrated by order of the Arcadians, by whom the Elians were at that time reduced very low: this, as well as thoſe managed by the inhabitants of Piſa, they called ανολυμπιαδας, that is, "unlawful Olympiads;" and left them out of their annals, in which the names of their victors and other occurrences were regiſtred.

ANOMALISTICAL, Year, in aſtronomy, the time that the earth takes to paſs through her orbit: it is alſo called the Periodical Year. The ſpace of time belonging to this year is greater than the tropical year, on account of the proceſſion of the equinoxes.

ANOMALOUS, a term applied to whatever is irregular, or deviates from the rule obſerved by other things of the like nature.

ANOMALY, or Anomalous *Verbs*, in grammar, are ſuch as cannot be conjugated conformably to the paradigm of their conjugation.

In Latin, the verb *lego* is the paradigm of the third conjugation; and runs thus, *lego, legis, legit:* By the ſame rule it ſhould be *fero, feris, ferit*; but we ſay *fero, fers, fert: fero*, then, is an anomalous verb.

In Engliſh the irregularity relates often to the preter tenſe and paſſive participle: for example, *give*, were it formed according to rule, would make *gived* in the preter tenſe and paſſive participle; whereas, in the former, it makes *gave*, and in the latter *given*.

ANOMALY, in aſtronomy, an irregularity in the motion of the planets, whereby they deviate from the aphelion or apogee.

ANOMIA, in the Linnæan ſyſtem of zoology, a genus of inſects belonging to the order of vermes teſtacea. The ſhell is bivalve, and the valves are unequal. One valve is perforated near the hinge; affixed by that perforation to ſome other body. There are 27 ſpecies of the anomia; of which only two are natives of the Britiſh ſeas, viz. 1. The ephippium, with the habit of an oyſter; the one ſide convex, the other flat; perforated; adherent to other bodies, often to oyſter-ſhells, by a ſtrong tendinous ligature; colour of the inſide perlaceous. Size, near two inches diameter. 2. The ſquammula, with ſhells reſembling the ſcales of fiſh; very delicate and ſilvery, much flatted, perforated, and very ſmall. Adheres to oyſters, crabs, lobſters, and ſhells. The ſpecies of this genus are commonly called *Beaked cockles*. No name has been given to the fiſh that inhabit it; the recent ſhells of this kind are ſo very rare, that there is ſcarcely one to be found perfect. They are, perhaps, as well as that which has given its form to the *corna amonis*, inhabitants of the deepeſt parts of the ocean; conſequently it muſt be ſome extraordinary agitation of that great body of water that can bring them at all to our knowledge in their recent ſtate.

The foſſile ſpecies of the Anomia genus are uncommonly numerous in chalk-pits, limeſtone-quarries; and, on ploughed lands.

ANOMOEANS, in eccleſiaſtical hiſtory, the name by which the pure Arians were called in the fourth century, in contradiſtinction to the Semi-Arians. The word is formed from the Greek, ανομοιος, *different, diſſimilar:* For the poor Arians aſſerted, that the Son was of a nature different from, and in nothing like, that of the Father: on the contrary, the Semi-Arians acknowledged a likeneſs of nature in the Son; at the ſame time that they denied, with the pure Arians, the conſubſtantiality of the world.

The Semi-Arians condemned the Anomœans in the council of Seleucia; and the Anomœans in their turn condemned the Semi-Arians in the councils of Conſtantinople and Antioch, eraſing the word ομοιος, *like*, out of the formula of Rimini and that of Conſtantinople.

ANOMORHOMBOIDIA, in natural hiſtory, is the name of a genus of ſpars; the word is derived from the Greek ανωμαλης, *irregular*, and ϱομϐοιδης a *rhomboidal* figure.

The bodies of this genus are pellucid cryſtalline ſpars, of no determinate or regular external form, but always breaking into regularly rhomboidal maſſes; eaſily fiſſile, and compoſed of plates running both horizontally and perpendicularly through the maſſes, but cleaving more readily and evenly in an horizontal, than in a perpendicular direction; the plates being always compoſed of irregular arrangements of rhomboidal concretions.

This genus contains five known ſpecies, viz. 1. A white, bright, and ſhattery one; found in great quantities in the lead-mines of Derbyſhire, Yorkſhire, and Wales. 2. A milk-white, opake, and ſhattery one, found in France, Germany, and Wales. 3. A hard, dull, ſnow-white one, found in the mines of Derbyſhire, and in many of the northern counties. 4. A hard grey and pellucid one, found in the lead-mines of Yorkſhire, and very common in Germany. And, 5. A pellucid and colourleſs one found in the lead mines of Derbyſhire and Yorkſhire. All of which have in ſome degree the double refraction of iſland cryſtal.

ANONIS, in botany, ſynonymous with Ononis, or Reſt-harrow.

ANONYMOUS, in grammar, implies, ſomething that is nameleſs, or of which the name is concealed. It is a term uſually applied to books which do not expreſs the author's name, or to authors whoſe names are unknown.

Anonymous, in commerce, are partnerſhips in trade, which are not carried on under any particular name, but each of the partners trades viſibly on his own account, and in his own name; and finally all the partners give an account of their profit or loſs in trade. Theſe ſorts of partnerſhips, which are common in France, are concealed, and known only to the parties themſelves.

Anonymous *Partnerſhips in Trade*, where perſons of fortune and quality depoſit ſums of money, in order to ſhare the profits. To this purpoſe, thoſe who furniſh the capital have no trouble in carrying on the trade, nor do their names appear to be any way intereſted therein. Thoſe kinds of partnerſhips are uſual in France.

Anonymous, in law. The ſending anonymous letters demanding money, &c. is felony by the Black Act, 9 Geo. I. chap. 22.

ANOREXIA, Anorexy, in phyſic, implies, a want of appetite, or a loathing of food. The diſorder is either original or ſymptomatic. When it is original, its cauſes are, bad diet, too free drinking, voraciouſneſs, &c. In which caſes, a vomit or two of ipecacuanha may be taken; and temperance, a light but cordial nouriſhing diet, and daily exerciſe, perſiſted in, will generally effect a recovery. But it is more frequently a ſymptom of ſome other diſorder; and then the cure depends on the removal of the original one.

ANOTTA, or Arnotta, in dyeing, implies, an elegant red colour, formed from the pellicles or pulp of the ſeeds of the Bixa, a tree common in South America. It is alſo called Terra Orleana, and Roucou.

Anotta is ſaid to be a ſucceſsful remedy in bloody-fluxes. The roots have much the ſame properties with the wax; but theſe are obſerved to work more powerfully by the urinary paſſages.

ANPITS, in military ſcience, denotes a kind of breaſt work, uſually denominated barbacan.

ANSÆ, or Anses, in aſtronomy, implies the handles or parts of Saturn's ring which project beyond the diſk of that planet.

ANSARIANS, in hiſtory, denotes a people of Syria, ſo called in the country, but ſtyled in Deliſſe's maps *Enſarians*, and in thoſe of D'A Danville, *Naſſaris*.

ANSATUM Telum, in ancient hiſtory, denotes a kind of beard on the point of the javelins, which prevented their going through the body, whilſt at the ſame time it helped to ſecure the wounded perſon as a hooked priſoner. This weapon was only uſed in battle.

ANSCOTE, in law, a ſynonyme of Scot or Anblote.

ANSER, in ornithology, the trivial name of a ſpecies of anas.

Anser, in aſtronomy, a ſmall ſtar, of the fifth or ſixth magnitude, in the milky way, between the ſwan and eagle, firſt brought into order by Hevelius.

ANSERES, the third order of birds in the Linnæan ſyſtem. See Syſtem of Ornithology.

Anseres *Order*, is diſtinguiſhed by a ſmooth beak, covered with a ſkin, gibbous at the baſe, and enlarged towards the apex; the jaw is denticulated, and the tongue fleſhy; the feet are formed for ſwimming, having their toes connected by a membrane, the legs are thick and ſhort; the body is bulky, and covered with a thin ſkin and feathers. This order is analogous to the belluæ in the claſs of Mammalia, Linnæi, Syſtema Naturæ.

ANSIBARII, or Ansivarii, an ancient people of Germany, ſituated in the neighbourhood of the Chauci.

ANSPESSADES, in the French armies, are a kind of inferior officers in the foot, below the corporals, but above the common centinels.

ANSWER, in law, implies a detail of facts refuted or acknowledged by a defendant, as ſet forth in a bill of complaint exhibited by a complainant in a court of equity, i. e. the chancery or the exchequer.

The formula is regular, but the particulars vary, as the caſe may be, and in the higher courts has but little weight unleſs proofs are exhibited by affidavit, and filed in the proper office.

In the practice of the common law, it is analogous to a rejoinder. For the ſcope of this term, ſee the *Univerſal Syſtem of* Law, in this work.

ANT, in zoology, the ſame as Formica and Termes.

Ant *Bear*, or *Ant-eater*, in zoology, the ſame as Myrmecophaga.

Ant *Eggs*, in natural hiſtory, a name popularly given to a kind of little white balls found in the banks or neſts of ants, ordinarily ſuppoſed to be the ova of this inſect.

Modern naturaliſts have obſerved, that theſe are not the ant's eggs, but the young brood themſelves in their firſt ſtate; for they are ſo many little vermiculi wrapped up in a film, or ſkin, compoſed of a ſort of ſilk, which they ſpin out of themſelves as ſilk-worms and caterpillars do.

At firſt they are hardly obſerved to ſtir; but, after a few days continuance, they exhibit a feeble motion of flexion and extenſion; and begin to look yellowiſh and hairy, and are ſhaped ſomewhat like ſmall maggots, in which ſhape they grow up till they are almoſt as large as ants.

When they paſs their metamorphoſis, and appear in their proper ſhape, they have a ſmall black ſpeck on them cloſe to the anus of the included ant. Theſe are brought up every morning in ſummer, near the top of the bank, where they are lodged all the warm part of the day, within reach of the ſun's influence; and at night, or if it be cool, or like to rain, they carry them down to a greater depth; ſo that one may dig a foot in depth to come at them. The true ants eggs are the white ſubſtance which, upon opening their banks, appear to the eye like the ſcatterings of fine white ſugar, or ſalt, but very ſoft and tender. If examined by a microſcope, it is found to conſiſt of ſeveral pure, white appearances, in diſtinct membranes, all figured like the leſſer ſort of birds eggs, and as clear as a fiſh's bladder. The ſame ſubſtance is found in the bodies of the ants themſelves. On this ſpawn, when emitted, they lie in multitudes, to brood, till in ſome time it is turned into little vermicles as ſmall as mites, commonly called ants-eggs.

Ant *Hills*, are little hillocks of earth, which the ants throw up for their habitation and the breeding of their young. They are a very great miſchief to dry paſtures, not only by waſting ſo much land as they cover, but by hindering the ſcythe in mowing the graſs, and yielding a poor hungry food that is pernicious to cattle. The manner of deſtroying them is to cut them into four parts from the top, and then dig into them ſo deep as to take out the core below, ſo that, when the turf is laid down again, it may lie ſomewhat lower than the level of the reſt of the land: by this means it will lodge the rain and prevent the ants from returning to the ſame place, which otherwiſe they would certainly do. The earth that is thus taken out muſt be ſcattered to as great a diſtance every way as may be, otherwiſe they will collect it together and make another hill juſt by. The proper time for doing this is in winter; and if the places be left open, the froſt and rains of that time of the year will deſtroy the reſt. Human dung is an excellent remedy, as is proved by experiment; for it will kill great numbers of them, and drive all the reſt away, if only a ſmall quantity of it be put into their hills.

Captain Cook gives the following account of a very peculiar kind of ants, which he met with at Botany Bay. "They are as green as a leaf. They live upon trees, where they build their neſts. Theſe neſts are of a very curious ſtructure: they are formed by bending down ſeveral of the leaves, each of which is as broad as a man's hand; they glue the points of them together, ſo as to form a purſe. The viſcus uſed for this purpoſe is an animal juice, which nature has enabled them to elobrate. Their method of firſt bending down the leaves our naturaliſts had not an opportunity to obſerve; but they ſaw thouſands uniting all their ſtrength to hold them in this poſition, while other buſy multitudes were employed within, in applying the gluten that was to prevent their returning back. To ſatisfy themſelves that the leaves were bent and held down by the efforts of theſe diminutive artificers, our people diſturbed them in their work, and, as ſoon as they were driven from their ſtation, the leaves on which they were employed ſprang up with a force much greater than they could have thought them able to conquer, by any combination of their ſtrength."

Acid of Ants, an acid produced by diſtilling a great number of theſe inſects, either without addition, or with water. It reſembles vinegar in many reſpects; but differs from it in forming cryſtals with magneſia, iron, and zinc. Its attractions are not yet determined, but are ſuppoſed to coincide with thoſe of vinegar.

ANTA, in the ancient architecture, was a ſquare pilaſter, placed at the corners of buildings.

ANTACIDS, in pharmacy, an appellation given to all medicines proper to correct acid or ſour humours.

Under the claſs of antacids come, 1. Abſorbents; as chalk, coral, ſea-ſhells, hæmatites, and ſteel-filings. 2. Obtundents; as oils and fats. 3. Immutants; as lixivious ſalts, and ſoaps.

ANTÆUS, in fabulous hiſtory, was a name given to a giant of Libya, ſon of Neptune and Terra. Deſigning to build a temple to his father, of mens ſculls, he ſlew all he met; but Hercules fighting him, and perceiving the aſſiſtance he received from his mother (for by a touch of the earth he refreſhed himſelf when weary) lifted him up from the ground, and ſqueezed him to death.

ANTAGONIST, in a general ſenſe, denotes an adverſary, eſpecially in ſpeaking of combats, games, and literary diſputes.

Antagonist *Muſcles*, in anatomy, thoſe which have oppoſite functions; as flexors and extenſors, abductors and adductors, &c.

ANTALGIC, in medicinal preparation, amounts to a literal definition of Anodynes.

ANTALIUM, Antale or Antalus, in natural hiſtory, denominates a ſmall ſea ſhell of a tubular form, ſometimes ſtiled tubulus marinus. It is in length about an inch and an half, and not thicker than a large ſized quill, but ſomewhat taper, and fluted from end to end. Its colour is generally a pale green, and ſometimes white. It is an acid reſolvent, if uſed medicinally, greatly tending to dry up humours.

ANTANACLASIS ,in rhetoric, ſignifies a figure which repeats the ſame word, but in a different ſenſe; as dum vivimus, vivamus.

ANTAGOGE, in rhetoric, a figure by which, when the accuſation of the adverſary is unanſwerable, we load him with the ſame or other crimes.

ANTANISOPHYLLUM, in botany, a ſynonyme with hogweed.

ANTAPHRODISIACS, in pharmacy, imply medicines proper to diminiſh ſemen, and conſequently extinguiſh or leſſen all deſires of venery.

ANTAPOCHA, in civil law, denotes an acknowledgment in writing for monies to be paid, in exoneration of ſome annual demand; this term is uſed in contradiſtinction to Apocha, which amounts to the ſame as a receipt for ſuch payment, and may be properly called a voucher, whilſt the former may be ſaid to be an acknowledged incumbrance.

ANTARCTIC, in a general ſenſe, denotes ſomething oppoſite to the arctic or northern pole. Hence antarctic circle is one of the leſſer circles of the ſpheres, and diſtant only 23° 30′ from the ſouth pole, which is likewiſe called antarctic pole for the ſame reaſon.

ANTARES, in aſtronomy, the name of a ſtar of the firſt magnitude, called alſo the ſcorpion's heart. Its longitude is 60° 13 14′′ of Sagittarius; and its latitude 4° 31′ 26′′S.

ANTASTROPHE, in rhetoric, is the ſame as Antipoſition.

ANTE, in heraldry, denotes that the pieces are let into one another in ſuch form as there is expreſſed; for inſtance, by dove-tails, rounds, ſwallow-tails, or the like.

ANTECANIS, in aſtronomy, implies the ſame as Canis Minor or Procyon.

ANTEAMBULONES, in Roman antiquity, denoted ſervants who went before perſons of diſtinction to clear the way before them. They uſed this formula, Date locum domino meo, i. e. Make room or way for my maſter.

ANTECEDENT, in rhetoric, in a general ſenſe, implies ſomething that goes before another, either in order of time or place.

Antecedent, in grammar, the words to which a relative refers.

Antecedent, in logic, is the firſt of the two propoſitions in an enthymeme.

Antecedent, in mathematics, is the firſt of two terms of a ratio, or that which is compared with the other.

ANTECEDENCE, Antecedency, or Antecedentia, in aſtronomy, implies an apparent motion of a planet towards the weſt, or contrary to the order of the ſigns.

ANTECESSOR, one that goes before. It was an appellation given to thoſe who excelled in any ſcience; and, in the univerſities of France, the teachers of law take the title anteceſſores in all their theſes.

ANTECURSORES, in the Roman hiſtory, implied a party of horſe detached before, partly to get intelligence, proviſions, &c. and partly to chuſe a proper place to encamp in. Theſe were otherwiſe called anteceſſores, and by the Greeks *prodromi*.

ANTEDATE, in law, implies a ſpurious or falſe date, prior to the true date of a bond, bill, or the like.

ANTEDILUVIAN, or Antidiluvian, in a general ſenſe, implies ſomething that exiſted before the flood or deluge.

Antediluvian *World*; the earth as it exiſted before the flood; and more properly comes under the theory of the earth.

ANTEDILUVIANS, a general name for all mankind who lived before the flood, and ſo includes the whole of the human race from Adam to Noah and his family. Refer to the various productions of Drs. Burnet, Woodward, Meſſrs. Whiſton, Gilbert, &c. &c. under the article, The Theory of the Earth, in order to gratify the curious reader, relative to the conjectures of the learned world on this intereſting ſubject.

ANTEJURAMENTUM, in ancient law, was called *juramentum calumniæ*, an oath which both accuſer and accuſed were to take before any trial or purgation. The accuſer was to ſwear that he would proſecute the criminal; and the accuſed to make oath, on the day he was to undergo the ordeal, that he was innocent of the crime charged againſt him.

ANTELOPE, in zoology, is deſcribed under the article Capra.

ANTELUCAN, in eccleſiaſtical writers, is applied to things done in the night or before day. Hence we find frequent mention of the antelucan aſſemblies of the ancient Chriſtians in times of perſecution.

ANTEMURALE, in the ancient military art, denotes much the ſame with what the moderns call an out-work.

ANTENATI, in modern Engliſh hiſtory, is chiefly underſtood of the ſubjects of Scotland, born before king James the Firſt's acceſſion to the Engliſh crown, and alive after it. Contradiſtinguiſhed from thoſe who were denominated poſtnati, or born after it. The antenati were conſidered as aliens in England, whereas the poſtnati claimed the privilege of natural ſubjects.

ANTENATUS, in law, ſignifies the eldeſt ſon or heir male in tail general, uſually called aiſné. Hence it ſometimes implies the ſon of a former marriage, when ſpeaking of the iſſue of a ſubſequent marriage.

ANTENCLEMA, in oratory, is where the whole defence of the perſon accuſed turns on criminating the accuſer. Such is the defence of Oreſtes, or the oration for Milo: *Occiſus eſt, ſed latro. Exſectus, ſed raptor.*

ANTENICENE, in eccleſiaſtical writers, denotes a thing or perſon prior to the firſt council of Nice. We ſay the Antenicene faith, Antenicene creeds, Antenicene fathers.

ANTENNÆ, in the hiſtory of inſects, ſlender bodies with which nature has furniſhed the heads of theſe creatures, being the ſame with what in Engliſh are called horns or feelers.

ANTENUPTIAL, in law, implies any article that entitles a woman to ſeek for redreſs in a court of judicature, for a breach of marriage. Hence, antenuptial promiſes in the preſence of two credible witneſſes, will always carry a verdict in an honourable cauſe.

All things preſented previous to marriage, are called antenuptial preſents, and are in the gift and diſpoſal of the wife after the conſummation of marriage. In all other cards, deeds of ſettlement are neceſſary.

ANTEPAGMENTA, in ancient architecture, the jambs of a door. They are alſo ornaments, or garniſhings, in carved work, of men, animals, &c. made either of wood or ſtone, and ſet on the architrave.

ANTEPENULTIMA, in grammar, ſignifies the third ſyllable of a word from the end, or the laſt ſyllable but two.

ANTEPILANI, in the Roman armies, a name given to the haſtati and principes, becauſe they marched next before the triarii, who were called pilani.

ANTEPILEPTICS, among phyſicians, expreſs all thoſe medicines eſteemed good in the epilepſy.

ANTEPOSITION, a grammatical figure, by which a word, according to the ordinary rules of Syntax ought to follow another, comes before it. As when, in the Latin, the adjective is put before the ſubſtantive, the verb before the nominative caſe, &c.

ANTEPREDICAMENTS, among logicians, certain preliminary queſtions which illuſtrate the doctrine of predicaments and categories.

ANTERIOR, denotes ſomething placed before another, either with reſpect to time or place.

ANTEROS, in mythology, one of the two cupids who were the chief of the number. They are placed at the foot of the Venus of Medica; this is repreſented with a heavy and ſullen look, agreeably to the poetical deſcription of him, as the cauſe of love's ceaſing. The other was called Eros.

ANTESIGNANI, in the Roman armies, ſoldiers placed before the ſtandards, in order to defend them, according to Limpſius; but Cæſar and Livy mention the Anteſignani as the firſt line, of heavy-armed troops. The Velites, who uſed to ſkirmiſh before the army, were likewiſe called Anteſignani.

ANTESTATURE, in fortification, implies a ſmall retrenchment made of paliſadoes, or ſacks of earth, with a view to diſpute with an enemy the remainder of a piece of ground.

ANTESTARI, in Roman antiquity, ſignifies to bear witneſs againſt any one who refuſed to make his appearance in the Roman courts of judicature, on the day appointed, and according to the tenor of his bail. The plaintiff, finding the defendant after ſuch a breach of his engagement, was allowed to carry him into court by force, having firſt aſked any of the perſons preſent to bear witneſs. The perſon aſked to bear witneſs in this caſe, expreſſed his conſent by turning his right ear, which was inſtantly taken hold of by the plantiff, and this was to anſwer the end of a ſubpœna. The ear was touched upon this occaſion, as the ſeat of memory, and therefore the ceremony was a ſort of caution to the party to remember his engagement.

ANTEVIRGILIAN Husbandry, an appellation given to Mr. Tull's method of horſe-hoeing huſbandry.

ANTHELION, a ſynonyme of Corona and Parhelion.

ANTHELIX, in anatomy, the inward protuberance of the external ear, being a ſemicircle within, aad almoſt parallel to the helix.

ANTHELMA, ſignifies the Indian pink.

ANTHELMINTICS, among phyſicians, medicines proper to deſtroy worms.

ANTHEM, a church-ſong performed in cathedral ſervice by choriſters, who ſung alternately. It was uſed to denote both pſalms and hymns, when performed in this manner. But, at preſent, an anthem is uſed in a more confined ſenſe, being applied to certain paſſages taken out of the Scriptures, and adapted to a particular ſolemnity.

Anthems were firſt introduced in the reformed ſervice of the Engliſh church, in the beginning of the reign of queen Elizabeth.

ANTHEMIS Camomile or Chamomile, a genus of the polygamia ſuperflua order, belonging to the ſyngeneſia claſs of plants; and in the natural method ranking under the 49th order, Compoſitæ diſcoides. The eſſential characters are theſe: The receptaculum is chaffy; there is no pappus; the calyx is hemiſpheric and ſubequal; and the florets of the ray are more than five.

There are 17 ſpecies: the moſt remarkable of which are the following: viz.

1. The nobilis, or common camomile, grows in plenty upon commons, and other waſte land. It is a trailing perennial plant, which puts out roots from the branches, by which it ſpreads and multiplies greatly. Of this kind there is a variety with double leaves.

2. The pyrethrum, or pillatory of Spain, is a perennial plant, which grows naturally in Spain and Portugal, from whence the roots are brought to this country.

3. The tinctoria, with ſawed winged leaves, is a perennial plant, which flowers from June to November.

4. The Arabica, with a branching empalement. The ſeeds of this ſpecies were brought from Africa by the late Dr. Shaw, and diſtributed to many curious botaniſts in this and other countries of Europe.

The firſt ſort may be very eaſily propagated by procuring a few ſlips in the ſpring, and planting them about a foot diſtant from each other, when they will ſoon cover the ground.

The other ſorts may be propagated from ſeeds ſown in the ſpring, and will require no other care than to be kept free from weeds.

The firſt and ſecond ſorts are uſed in medicine. The firſt have a ſtrong, not ungrateful, aromatic ſmell, and a very bitter nauſeous taſte.

They are accounted carminative, aperient, emollient, and in ſome meaſure anodyne; and ſtand recommended in flatulent colics, for promoting the uterine purgations, in ſpaſmodic pains, and the pains of childbed-women.

Theſe flowers are alſo uſed externally in diſcutient and antiſeptic fomentations, and in emollient clyſters. They enter the *decoctum pro enemate and decoctum pro fomento* of our pharmacopœias. A ſimple watery infuſion of them taken in a tepid ſtate, is at preſent frequently employed to promote the operation of emetics. The principal uſe of pyrethrum in the preſent practice is as a maſticatory, for promoting the ſalival flux, and evacuating viſcid humours from the head and neighbouring parts; by this means it often relieves the tooth-ach, ſome kinds of pains of the head, and lethargic complaints.

ANTHERA, or Antheræ, among botaniſts, expreſſes that part of the ſtamen which is fixed on the top of the filamentum, within the corolla: it contains the pollen or fine duſt, which, when mature, it emits for the impregnation of the plant, according to Linnæus.

ANTHERICUM, Spider-Wort; a genus of the monogynia order, belonging to the hexandria claſs of plants; and, in the natural method, ranking under the 10th order, Coronariæ.

There are nine ſpecies; viz. 1. The ramoſum, with a branching ſtalk. 2. The liliago. Theſe are perennial plants, natives of Spain, Portugal, and other warm countries.

They flower in June and July, and the ſeeds are ripe in September. 3. The truteſcens, with a ſhrubby ſtalk, it produces many ligneous branches from the root, each ſupporting a plant with long taper leaves, in ſhape like thoſe of an onion, and full of a yellow pulp, very juicy. This ſpecies is a native of the Cape of Good Hope.

The other ſpecies, being of little or no value, do not admit of any deſcription.

The two firſt are propagated by ſeeds, which ſhould be ſown in a warm ſituation, on a bed of light ſandy earth. The third requires ſhelter in winter, but will live in the open air, if planted cloſe to the warm wall.

ANTHESPHORIA, in antiquity, a Sicilian feſtival inſtituted in honour of Proſerpine. It ſeems to be the ſame thing with the floriſertum of the Latins, and anſwers to the harveſt-home among us.

ANTHESTERIA, in antiquity, was a feaſt celebrated by the Athenians in honour of Bacchus. The moſt natural derivation of the word is from the Greek ανθος (*flos*), a flower, it being the cuſtom at this feaſt to offer garlands of flowers to Bacchus; laſted three days.

ANTHESTERION, in ancient chronology, was the ſixth month of the Athenian year. It contained 29 days; and anſwered to the latter part of our November and beginning of December. It had its name from the feſtival anthereſteria kept in it.

ANTHIA, in ichthyology, a trivial name of the ſalx venetorum, or ſickle fiſh.

ANTHIAS, a ſynonyme in ichthyology, for a ſpecies of the labrus.

ANTHINE, or Anthinos, in hiſtory, is a record, implying the mixture of wine and oil in one veſſel for immediate uſe.

ANTHISTIRIA, in botany, is a genus of the trigynia order, belonging to the triandria claſs of plants; and, in the natural method, ranking under the 4th order, Gramina. The generic characters are: The calyx is a four-valved glume, equally cleft to the baſe; the corolla is a two-valved glume; the ſtamina conſiſt of three ſhort ſlender filaments; the antheræ oblong and erect; the piſtillum has an oblong germen; the ſtyli are two; and the ſtigmata are clavated and hairy; there is no pericarpium, except a cloſed calyx; the ſeed is oblong and furrowed. There is only one ſpecies of this graſs, the ciliata or fringed anthiſtiria, a native of India.

ANTHOCEROS, or Horn Flower, is a genus of the order of algæ, belonging to the cryptogamia claſs of plants; and, in the natural method, ranking under the 57th order, Algæ. The eſſential generic characters are: The calyx of the male is ſeſſile, cylindric, and entire; the antheræ (one) is ſubulated, very long, and two-valved; the calyx of the female is monophyllous, divided into ſix parts, and expanding; the ſeeds are about three, naked and roundiſh.

There are only three ſpecies of the anthoceros; viz. The punctatus, or ſpotted anthoceros, a native of Britain; the lævis, a native of Europe and America; and the multifidus, a native of Germany.

ANTHOLOGION, is the title of the ſervice-book uſed in the Greek church. It is divided into twelve months, containing the offices ſung throughout the year, on the feſtivals of our Saviour, the Virgin, and remarkable ſaints days.

ANTHOLOGY, or **Anthologia**, in literature, denotes a ſelection of beautiful paſſages from any authors. It is alſo the name given to a collection of epigrams taken from ſeveral Greek poets.

ANTHOLYZA, **Mad Flower**, a genus of the monogynia order, belonging to the triandria claſs of plants; and, in the natural method, ranking under the 6th order, Enſatæ. The eſſential characters are theſe: the calyx is tubular, irregular, and bent back; and the capſule is beneath the flower. There are two ſpecies; viz.

1. The ringens, whoſe flower-ſlips ſpread aſunder. This hath red, round, bulbous roots, from which ariſe ſeveral rough, furrowed leaves, near a foot long, and half an inch broad. The flower appears in June, and the ſeeds ripen in September.

2. The ſpicata, with narrow furrowed leaves, is in ſhape and ſize like the vernal crocus.

Both theſe ſpecies are natives of Africa, from whence their ſeeds are firſt obtained, and raiſed in the Dutch gardens.

The anthyloza may be propagated by offſets, which it ſends off in pretty great plenty; or by ſeeds, which are ſometimes perfected in Europe.

ANTHONY, or *Knights of* **St. Anthony**, was a military order, inſtituted by Albert, Duke of Bavaria, Holland, and Zealand, when he deſigned to make war againſt the Turks in 1382. The knights wore a collar of gold, made in form of a hermit's girdle, from which hung a ſtick, with a little bell, as they are repreſented in St. Anthony's pictures.

St. **Anthony** alſo gives the denomination to an order of religious, founded in France about the year 1095, to take care of thoſe afflicted with St. Anthony's fire.

St. **Anthony's** *Fire*, a name popularly given to the eryſipelas. Apparently it took this denomination, as thoſe afflicted with it made their peculiar application to St. Anthony of Padua for a cure. It is known, that anciently particular diſeaſes had their peculiar ſaints: thus, in the ophthalmia, perſons had recourſe to St. Lucia; in the tooth-ach, to Saint Apollonia; in the hydrophobia, to Saint Hubert, &c.

ANTHOPHYLLI, or **Antophali**, in botanical language, expreſſes a larger ſpecies of cloves.

ANTHORA, in botany, is the trivial name of a ſpecies of Aconitum.

ANTHORISMUS, in rhetoric, denotes a contrary deſcription or definition of a thing from that given by the adverſe party.

For example; if the plaintiff urge, that to take any thing away from another, without his knowledge or conſent, is a theft; this is called ορος, or definition. If the defendant reply, that to take a thing away from another, without his knowledge or conſent, provided it be done with deſign to return it to him again, is not theft; this is an Ανθορισμος.

ANTHOS, ανθος, a flower, in botany ſignifies roſemary only. It implies alſo the elixir of gold, as well as a medicine extracted from pearls.

ANTHOSMIAS, the ſame as Anthine, or wine and oil mixed with the juice of odoriferous herbs; a choice kind of beverage uſed by the ancients at their feſtivals and public rejoicings.

ANTHOSPERMUM, the **Amber Tree**, a genus of the diœcia order, belonging to the polygamia claſs of plants; and, in the natural method, ranking under the 47th order, Stellatæ. For the characters ſee Syſtem of **Botany**.

There are three ſpecies; viz. The Æthiopica, ciliare, and herbacea; but the firſt is moſt generally known in the gardens of the curious. Its beauty conſiſts in its ſmall ever-green leaves, which grow as cloſe as heath. Theſe being bruiſed between the fingers, emit a very fragrant odour; whence the name amber tree.

This plant is eaſily propagated by cuttings during the ſummer-months, in a border of light earth, where they will take root in ſix weeks time.

ANTHOXANTHUM, or **Vernal Grass**, a genus of the digynia order, belonging to the diandria claſs of plants; and, in the natural method, ranking under the 4th order, Gramina. The eſſential characters are: The calyx is a bivalved gluma, with one flower; the corolla is bivalved, obtuſe, and without any awn.

There are three ſpecies; viz. the odoratum, or ſpring-graſs, a native of Britain; the indicum, a native of India; and the paniculatum, a native of the ſouthern parts of Europe.

ANTHRACIS, **Anthracias**, or **Anthracitis**, were names promiſcuouſly uſed by ancient naturaliſts for very different foſſils; viz. the carbuncle, hæmatites, and a kind of aſteria.

ANTHRACOSIS, in medicine, implies, a corroſive ſcaly ulcer either in the bulb of the eye or the eye-lids.

ANTHRAX, ανθραξ, a Greek term, literally ſignifying a burning coal, uſed by the ancients to denote a gem, generally known by the name of *carbuncle*. Alſo it denoted a diſeaſe.

Anthrax, likewiſe ſignifies lithanthrax or pitcoal.

ANTHROPOGLOTTUS, among zoologiſts, is an appellation given to ſuch animals as have tongues reſembling that of mankind; and particularly to the parrot kind.

ANTHROPOGRAPHY, or **Anthrographia**, denotes the deſcription of the human body, its parts and ſtructure.

ANTHROPOLATRÆ, in church-hiſtory, is an appellation given to the Neſtorians, on account of their worſhipping Chriſt, notwithſtanding they believed him to be a mere man.

ANTHROPOLATRIA, ſignifies paying divine honours to a man; and is ſuppoſed to be the moſt ancient kind of idolatry.

ANTHROPOLITES, is a term which denotes petrifactions of the human body, as thoſe of quadrupeds are called zoolites.

The generality of naturaliſts aſſure us of real anthropolites being ſometimes found. And, as it is univerſally admitted that the zoolites are frequently ſeen, what negative argument therefore can be brought againſt the exiſtence of the others? One in particular was diſcovered at Aix en Florence, Anno 1583, in a rocky cliff, the cerebrum whereof, when ſtruck againſt a piece of ſteel, produced ſparks, the bones being at the ſame time friable. The human vertebræ, fragments or portions of the tibia, and even the whole cranium itſelf, have been ſeen in an abſolute ſtate of petrification. Some of theſe are ſaid to appear vitriolated or mineralized.

As to the petrified bones of pretended giants, they are more probably real zoolites, the bones of the larger animals. Some are only indurated; others calcined, vitriolated, or mineralized; ſome, again, are ſimply incruſted; whilſt others have been proved completely petrified.

ANTHROPOLOGY, a diſcourſe upon human nature.

Anthropology, in theology, denotes a mode of ſpeaking of God, after the manner of men; by attributing human parts and paſſions to him.

We have frequent inſtances of anthropology in Holy Scripture; by which we are only to underſtand what God hath done.

ANTHROPOMANCY, a ſpecies of divination, performed by inſpecting the intrails of a human body.

ANTHROPOMETRIA, implies a deſcription of the human body, according to the juſt dimenſions, of length, breadth, and thickneſs, conſidered comparatively to each other.

ANTHROPOMORPHA, in the Linnæan ſyſtem of nature, that claſs of animals which in ſome degree reſemble the human form. See the Claſſification of Natural Hiſtory.

ANTHROPOMORPHISM, in the language of divines, implies the ſectary, or erroneous principles of the Anthropomorphites.

ANTHROPOMORPHITE, in a general ſenſe, ſignifies a perſon who attributes to God the figure of a man.

The word comes from the Greek, ανθρωπος, man, and μορφη, ſhape.

Anthropomorphites, in eccleſiaſtical hiſtory, were a ſect of ancient heretics, who, taking every thing ſpoken of God in Scripture, in a literal ſenſe, particularly, the paſſage in Geneſis, where it is ſaid, that God made man after his own image, ſo maintained that God had a human form.

Epiphanius calls the Antropomorphites, Audiani, or Odiani, from Audius, the ſuppoſed founder of the ſect; who lived, about the time of Arius, in Meſopotamia. St. Auguſtine calls them Vadiani.

ANTHROPOMORPHOUS, ſomething that bears the figure or reſemblance of a man. Naturaliſts give inſtances of anthropomorphous plants, anthropomorphous minerals, &c. Theſe generally come under the claſs of what they call luſus naturæ, or monſters.

ANTHROPOPATHY, a figure or expreſſion, by which ſome paſſion is attributed to God, that properly belongs only to man.

ANTHROPOPHAGI, ſignifies men-eaters it is compounded of the Greek ανθρωπος, man, and Φαγειν, *edere*, to eat.

The Cyclops, the Leſtrygons, and Scylla, are all repreſented in Homer as anthropophagi, or man-eaters; and the female phantoms, Circe, and the Syrens, firſt bewitched with a ſhew of pleaſure, and then deſtroyed. This, like the other parts of Homer's poetry, had a foundation in the manners of the times preceding his own. It was ſtill in many places the age ſpoken of by Orpheus,

> When men devoured each other like the beaſts,
> Gorging on human fleſh.——

Hiſtory, gives us divers inſtances of perſons driven by exceſs of hunger to eat their own relations. And alſo out of revenge and hatred, where ſoldiers in the heat of battle have been known to be carried to ſuch an exceſs of rage, as to tear their enemies with their teeth.

The violence of love has ſometimes produced the ſame effect as the exceſs of hatred.

Among the Eſſedonian Scythians, when a man's father died, his neighbours brought him ſeveral beaſts, which they killed, mixed up their fleſh with that of the deceaſed, and made a feaſt.

Among the Maſſageti, when any perſon grew old, they killed him and eat his fleſh; but if the party died of ſickneſs, they buried him, eſteeming him unhappy.

Idolatry and ſuperſtition have occaſioned the eating more human fleſh than both love and hatred put together.

There are few nations but have offered human victims to their deities; and it was an eſtabliſhed cuſtom to eat part of the ſacrifices they offered.

It appears pretty certain from Dr. Hawkeſworth's account of the voyages to the South Seas, that the inhabitants of New Zealand eat the bodies of their enemies. Mr. Petit has a learned diſſertation on the nature and manners of the Anthropophagi. Among other things, he diſputes whether or no the Anthropophagi act contrary to nature?

The philoſophers, Diogenes, Chryſippus, and Zeno, followed by the whole body of ſtoics, held it a very reaſoneable thing for men to eat each other.

According to Sextus Empiricus, the firſt laws were thoſe made to prevent men from eating each other, as been had done till that time.

The Greek writers repreſent Anthropophagi as univerſal before Orpheus.

Leonardus Floroventius informs us that having fed a hog with hog's fleſh, and a dog with dog's fleſh, found a repugnancy in nature to ſuch food; the former loſt all his briſtles; the latter its hair, and the whole body broke out in blotches.

If even this horrid practice of eating human fleſh originates from hunger, ſtill it muſt be perpetuated from revenge: as death muſt loſe much of its horror among thoſe who are accuſtomed to eat the dead; and where there is little horror at the ſight of death, there muſt be leſs repugnance to murder.

ANTHROPOPHAGIA, implies the habit of eating human fleſh; which is pretended to be the effect of a diſeaſe, that leads people affected with it to eat every thing alike. Some conſider it as a ſpecies of Pica.

The annals of Milan, furniſh an extraordinary inſtance of Anthropophagy.

"A Milaneſe woman, named Elizabeth, from a depraved appetite, like what women with child, and thoſe whoſe menſes are obſtructed, frequently experience, had an invincible inclination to human fleſh, of which ſhe made proviſion by enticing children into her houſe, where ſhe killed and ſalted them: a diſcovery of which having been made, ſhe was broken on the wheel and burnt in 1519."

ANTHROPOSCOPIA, ſignifies the art of judging a man's diſpoſition, from the lineaments of his body.

ANTHROPOSOPHIA, implies the ſcience of the nature of man, his ſtructure and compoſition, both internal and external.

ANTHROPOTHYSIA, denotes the inhuman practice of offering of human ſacrifices.

ANTHUMON, in the material medica of the ancients, ſignifies the epithymum, or dodder, growing upon thyme.

ANTHUS, in ornithology, ſignifies a ſynonyme of a ſpecies of the whin-chat or loxia.

ANTHYLLIS, in botany, is the kidney-votch or lady's finger; belonging to the diadelphia claſs and decandria order, ranking in the 32d order of the natural method, papilionaceæ.

The characters of which are few, viz. The calyx is ventricoſe, and the legumen round and well covered.

In the Linnean ſyſtem there are nine ſpecies enumerated, the chief of which are the following diſtinctions:

1. The Vulneraria with unequal winged leaves, a native of ſeveral parts of Europe.

2. The Montana or herbaceous wound wort, a native of France and Italy.

3. The Barba jovis, or ſilver-buſh with white leaves, a native of warm climates only.

4. The Cytiſoides, or ſhrubby wound wort, a native alſo of warm climates, although now to be found in ſeveral gardens in England.

The firſt and ſecond ſorts may be raiſed by ſeeds, and require no particular management, further than being kept free from weeds. The third and fourth may be propagated by cuttings planted any time from the latter end of May to the latter end of Auguſt, but are to be early removed on the approach of the winter and houſed; otherwiſe they will die by the ſlighteſt froſt, which the gardener muſt carefully guard againſt.

ANTHYPOMOSIA, in ancient law, was an oath taken by a proſecutor, declaring that the abſence of the party accuſed was not for any juſt cauſe, and therefore demanded that judgment.

ANTHYPOPHORA, in rhetoric, ſignifies a figure of ſpeech by which we covertly obviate a reaſon or objection.

ANTI, αντι, is a prepoſition uſed in compoſition with ſeveral words, both in Greek, Latin, French, and Engliſh, in different ſenſes.

In Engliſh, it ſignifies *oppoſite*; and is then derived from αντι, *contra, againſt.*

Anti, in matters of literature, is a title given to divers pieces written by way of anſwer to others, whoſe names are uſually annexed to the anti.

ANTIADES, in anatomy, ſignifies the glandules, kernels, tonſils, or almonds of the ears.

ANTIADIAPHORISTS, Antiadiaphoristæ, in church hiſtory, a name given, in the fourteenth century, to the rigid Lutherans, who diſavowed the epiſcopal juriſdiction.

ANTIBACCHIUS, in ancient poetry, a foot, conſiſting of three ſyllables; the two firſt long; and the third ſhort.

ANTIBARBAROUS, in literature, implies ſeveral works levelled againſt the uſe of barbarous terms and phraſes, chiefly in the Latin tongue.

ANTICADMIA, in pharmacy, denotes a ſpecies of mineral Cadmia, ſometimes alſo called pſeudo-cadmia.

ANTICARDIUM, in anatomy, ſignifies the pit of the ſtomach, or ſcrobiculus cordis.

ANTICATARRHAL, in medicine, is an epithet given to medicines preſcribed for catarrhs.

ANTICAUSOTICS, among phyſicians, denote medicines againſt burning fevers. In this ſenſe Juncker has given the deſcription of anticauſotic ſyrup.

ANTICHAMBER, ſignifies a room to wait in, till an audience is given.

ANTICHORUS, in botany, a genus of the octandria claſs, and monogynia order: it has a four-leaved calyx, four petals, an awl-ſhaped, four-celled capſule, with four valves, and many ſeeds. There is only one ſpecies, a native of Arabia.

ANTICHRESIS, in law, is a covenant, by which a perſon borrowing money of another, makes over his lands or goods to the lender, with the uſe and occupation of them, for the intereſt of the money lent.

ANTICHRIST, in a general ſenſe, denotes an adverſary of Chriſt, or one who denies that he has been upon earth.

The Antichriſt mentioned by the apoſtle John, 1 Ep. ii. 18. and and more particularly deſcribed in the book of Revelation, ſeems evidently to be the ſame with the man of ſin, &c. characteriſed by St. Paul in the ſecond chapter of his ſecond Epiſtle to the Theſſalonians.

ANTICHRISTIANISM, a ſtate or quality, in perſons or principles, which denominates them oppoſite to the kingdom of Chriſt.

ANTICHRISTIANS, in a religious ſenſe, denote the followers or worſhippers of Antichriſt.

Antichristians may alſo be denominated to be thoſe who believe in a falſe Meſſiah.

ANTICHTHON, in the Pythagorean ſyſtem of aſtronomy, denotes a globe of earth reſembling ours, but inviſible to us, becauſe on the oppoſite ſide of the ſun, that luminary being always interpoſed between this earth and the antichthon.

ANTICHTHONES, in geography, imply the inhabitants of oppoſite hemiſpheres. They are ſometimes alſo called antigenæ, or antipodes.

ANTICIPATION, implies the act of doing a thing before the time.

Anticipating a payment denotes the diſcharging it before it falls due.

Anticipation, in logic, denotes a preconceived opinion.

Anticipation, in medicine, implies thoſe diſeaſes where the ſymptoms belonging to ſome future period, appear in the beginning.

Anticipation, in the Epicurean philoſophy, denotes the idea of a thing, without which we cannot enquire concerning it.

Anticipation, in rhetoric, implies a figure generally called a Prolepſis.

ANTICK, in architecture, ſculpture and painting, denotes a fantaſtical compoſure of figures of different natures, ſexes, &c. which the Italians call *groteſca*, and the French *groteſque*.

ANTICLIMAX, in rhetoric, implies a figure, by which the progreſs of a diſcourſe deſcends from great to little.

ANTICNEMION, in anatomy, denotes the ſkin; or the fore prominent part of the tibia.

ANTICOR, among farriers, is uſually deſcribed as a preternatural ſwelling; but is really an inflammation in the gullet and throat; and is the ſame that, in human bodies, is called the angina, or ſquinancy.

ANTICUM, or Antæ, in architecture, denotes a porch before a door; alſo that part of a temple, which is called the outer temple, and lies between the body of the temple and the portico.

ANTICUS, *Serratus minor*, a ſynonyme of Serratus.

Anticus, *Peronæus*, a ſynonyme of Peronæus.

Anticus, *Tibialis*, a ſynonyme of Tibialis.

ANTIDACTYLUS, in poetry, implies that which is the reverſe of a dactyl, as conſiſting of three ſyllables, the firſt two of which are ſhort, and the laſt long.

ANTIDESMA, in botany, implies a genus of the pentandria claſs, and belonging to the dioecia order; whoſe genuine properties are as follow, viz. The calyx of the male is 5 leaved; having no corolla, the antheræ are bifid: the female calxy is 5 leaved; the corolla is wanting; the ſtigmata are 5; the being is cylindric and one ſeeded.

There is but one ſpecies, and that is denominated a native of the hither India.

ANTIDÆMONICI, in eccleſiaſtical hiſtory, a ſect who denied the exiſtence of devils, or evil ſpirits; alſo all ſpectres, incantations, witchcrafts, &c.

ANTIDISMA, in botany, a genus of the dioecia claſs and pentandria order, without an Engliſh name.

ANTIDORON, in eccleſiaſtical writers, a name given by the Greeks to the conſecrated bread, out of which the middle part, marked with the croſs, in which the conſecration reſides, being taken away by the prieſt, the remainder is diſtributed, after maſs, to the poor.

ANTIDOSIS, in antiquity, denotes an exchange of eſtates, practiſed by the Greeks on certain occaſions, and firſt inſtituted by Solon. It originated thus: When a perſon was nominated to an office, the expence of which he was not able to ſupport, he had recourſe to the antidoſis, that is, he was to ſeek for ſome citizen of better ſubſtance than himſelf, who was free from this, and other offices; in which caſe, the former was excuſed. But in caſe the perſon thus ſubſtituted denied himſelf to be the richeſt, they were to exchange eſtates, after this manner; the doors of their houſes were cloſe ſhut up and ſealed, that nothing might be conveyed away; then both took an oath to make a faithful diſcovery of all their effects; accordingly, within three days, a full diſcovery and exchange of eſtates was made.

ANTIDOTARY, a ſynonymous term with Diſpenſatory.

ANTIDOTE, in medicine, ſignifies a remedy taken to prevent the effects of poiſon, either by way of cure or preſervative.

Antidote, has the ſame ſignification with alexipharmic, alexiterial, and counterpoiſon.

ANTIGRAPHE, in antiquity, denotes a law-ſuit about kindred, whereby a perſon claimed relation to family.

ANTIGRAPHUS, in antiquity, an officer of Athens, who kept a counterpart of the apodecti, or chief treaſurer's accounts, to prevent miſtakes, and keep them from being falſified.

Antigraphus, a ſecretary or chancellor.

Antigraphus, in eccleſiaſtical hiſtory, denotes an abbreviator of the papal letters; and in the modern acceptation of the word, conſiſts in making minutes of bulls from the petitions agreed to by his holineſs, and renewing the bulls after engroſſing.

ANTIGUGLER, in mechanics, is a crooked tube of metal, ſo bent, ſo as to be eaſily introduced into the necks of bottles, and uſed in decanting liquors, without diſturbing them. For this purpoſe the bottle ſhould be a little inclined, and about half a ſpoonful of the liquor poured out, ſo as to admit an equal quantity of air; let one end of the bent tube be ſtopped with the finger, whilſt the other is thruſt into the body of the liquor near to the bubble of air already admitted. When the finger is taken off, the bottle will have vent, and the liquor will run out ſteadily and undiſturbed.

ANTIHECTICS, in medicine, ſignify remedies taken againſt hectical diſorders.

ANTIHECTICUM *Poterii*, in pharmacy, a celebrated chemical preparation, formerly much in practice; but now deſervedly laid aſide.

ANTILEXIS, in antiquity, denotes a new trial granted in the Athenian judicatories, where judgment had before paſſed againſt a party for non-appearance.

ANTILOGARITHM, denotes the complement of the logarithm of a ſine, tangent, or ſecant.

ANTILOGY, in literature, implies a contradiction between two paſſages, in an author, or book, on any one ſubject.

ANTILUTHERANS, in church hiſtory, denote a ſect among the ancient reformers, who maintained opinions, chiefly in relation to the euchariſt, different from thoſe of Luther.

ANTELOPE, a ſynonyme of the ſpecies capra, under which it is deſcribed.

ANTILYSSUS *Pulvis*, in medicine, is compoſed of equal parts of the lichen cinereus teareſtris & piper niger. It is reckoned uſeful in preventing the rabies canina.

ANTIMENSIUM, a kind of conſecrated table cloth, occaſionally uſed in the Greek church, in places where there is no proper altar.

Antimensium, in the Greek church, anſwers to the altareportabile, or portable altar, in the Latin church.

Antimensia is alſo applied to other tables, uſed in offices of religion, beſides thoſe on which the euchariſt is adminiſtered; i. e. ſuch as thoſe on which the hoſt is expoſed.

ANTIMENSIUS, an ancient officer in the Greek church, whoſe buſineſs was to introduce and place the communicants at the euchariſt.

ANTIMERIA, in grammar, denotes a figure by which one part of ſpeech is uſed for another; e. g. velle ſuum cuique eſt, for voluntas ſui cuique eſt; alſo populus late rex, for populus late regnans.

Antimeria, in a more reſtrained ſenſe, imports a figure, by which the noun is repeated inſtead of the pronoun.

The antimeria is frequent in the Hebrew, and is ſometimes retained in our verſion of the Old Teſtament, accordingly: e. g. Hear my voice, ye wives of Lamech; for my wives. Gen. ch. iv. ver. 23.

ANTIMETABOLE, in rhetoric, denotes a figure which ſets two things in oppoſition to each other.

This figure is twice exemplified in an apophthegm of Muſonius; which, on account of its excellence, is called aureum monitum, the golden maxim or precept; and of which the following is a tranſlation:

"Allowing the performance of an honourable action to be at-
"tended with labour; the labour is ſoon over, but the honour
"immortal: whereas, ſhould even pleaſure wait on the com-
"miſſion of what is diſhonourable, the pleaſure is ſoon gone, and
"the diſhonour eternal."

ANTIMETATHESIS, in rhetoric, is the inverſion of the parts or members of an Antitheſis. Such is that of Cicero, in Verrem, lib. iv. cap. 52. "Compare this peace with that war; the arrival of this governor with the victory of that general; his profligate troops with the invincible army of the other; the luxury of the former with the temperance of the latter; you will ſay, that Syracuſe was founded by him who took it; and taken by him, who held it when founded."

ANTIMONARCHICAL, in politics, is an appellation given to whatever oppoſes monarchy, or kingly government.

Antimonarchical is frequently uſed in the ſenſe of republican.

ANTIMONARCHOMACHI, or Antimonarchomachists, denote the maintainers of monarchical or abſolute power veſted by divine right in the perſons of princes. In which ſenſe, antimonarchomachi ſtand oppoſed to monarchomachi.

ANTIMONIALS, in medicine, denote preparations of antimony; or remedies of which antimony is the principal ingredient.

ANTIMONIATED, implies a medicine, or any thing elſe tinged with the qualities of antimony.

ANTIMONY, in natural hiſtory, is a mineral ſubſtance of a metalline nature; having all the ſeeming characters of a real metal, excepting malleability. It is a compound of a ſhining needle like ſtriæ: its maſſes have no determinate figure. It is made up of a ſemi-metallic ſubſtance, called its regulus, united with ſulphur. It is found in moſt parts of Europe.

There are two kinds of antimony; 1. Antimony native, or mineral, which is in the ſame ſtate as when dug out of the earth. 2. Antimony fuſed, ſo called, becauſe it has been actually fuſed, to ſeparate it from adhering to ſtones and earth. This operation which ought rather to be called liquation than fuſion, conſidering theſe words in their metallurgic ſenſe, is made in great perfection where it is dug.

Antimony is the ſtibium of the ancients; by the Greeks called *ςιμμι*. The reaſon of its modern denomination, antimony, is uſually referred to Baſil Valentine, a German monk, who, as the tradition relates, having thrown ſome of it to the hogs, obſerved, that, after purging them violently, they immediately grew fat upon it. This made him think, that, by giving his fellow-monks a like doſe, they would be the better for it. The experiment, however, ſucceeded ſo ill, that they all died of it; and the medicine, thenceforward, was called antimony, q. d. anti-monk.

Antimony *Ores*, are frequently found in fiſſures and veins at different depths, and often near the very ſurface, and variouſly accompanied with ſpars, cryſtals, ſulphurs, and other ſubſtances.

Antimony, *Ore of*, the way of running down antimony out of its ore by the aſſayers, ſee Syſtem of Metallurgy.

The moſt ready method of fuſing antimony, yet known, is by means of that mineral ſubſtance called cawk. A lump of this, of the bigneſs of a wallnut, thrown red-hot into a pound of antimony in fuſion, converts almoſt the whole ſubſtance of it into glaſs, fifteen ounces of clear and fine glaſs being thus produced; and what is very remarkable, the cawk itſelf never melts in the metal.

Antimony is ſuppoſed, by many chemiſts, to contain the ſeminal principles of all kind of metals; and accordingly the character by which it is denoted in their writings, is the ſame with the character of the earth; to denote that antimony is a kind of microſcoſm.

The modern uſes of antimony are very numerous, and important.

It is a common ingredient in ſpecula, or burning concaves, ſerving to give the compoſition a finer texture. It makes a part in bell metal; and renders the ſound more clear.

It is mingled with tin to make it more hard, white, and ſounding; and with lead, in the caſting of printers letters, to render them more ſmooth and firm.

It is alſo a general help in the melting of metals, and eſpecially in the caſting of cannon balls.

It is likewiſe made uſe of for the purifying and heightening the colour of gold. See Syſtem of Chemistry.

Antimony, at firſt, was of ſervice only in the compoſition of paint. Scripture deſcribes it to us as a ſort of paint, with which the women blacken their eye-brows. Jezebel underſtanding that Jehu was to enter Samaria, painted her eyes with antimony, or, according to the Hebrew, "put her eyes in antimony." As large black eyes were thought the fineſt, thoſe of both ſexes, who were careful of their beauty, rubbed their eyes, eye-lids, and round the eyes, with a needle dipped in a box of paint made of antimony, with a deſign of blackening them.

At this day the women of Syria, Aribia, and Babylonia, anoint and blacken themſelves about the eyes; and both men and women put black upon their eyes in the deſert, to preſerve them from the heat of the ſun, and the piercing of its rays.

M. Darvieux relates that the Arabian women border their eyes with a black colour made of tutty, which the Arabians call rehel. They draw a line of this kind of blacking without the corner of their eyes, to make them appear larger.

Iſaiah, in his enumeration of the ſeveral ornaments belonging to the daughters of Sion, has not forgot the needles which they made uſe of in painting their eyes and eye-lids.

Ezekiel, deſcribing the irregularities of the Jewiſh nation under the idea of a debauched woman, ſays, that ſhe bathed, and perfumed herſelf, and that ſhe anointed her eyes with antimony. Job ſhews ſufficiently how much antimony was in eſteem, by calling one of his daughters a veſſel of antimony, or a box to put paint in, *cornu ſtibii*.

Before the fourteenth century, antimoy had no place in medicine. But, about that time, Baſil Valentine, having found a method of preparing and correcting the dangerous qualities of its ſulphur, publiſhed a book, intituled Currus triumphalis Antimonii, in which he maintained it to be a certain remedy for all diſeaſes. Yet it remained in general neglect, till about the beginning of the ſixteenth century, when it was brought into practice by Paracelſus.

The parliament of Paris, immediately upon this reſtoration, condemned the uſe of it in form; and a phyſician, named Beſnier, having been found a delinquent, he was expelled the faculty.

To enumerate the various eſſences and compounds which bear the name of antimony would be improper in this place, as they will reſpectively have their deſcription under the heads or ſyſtems of PHARMACY and CHEMISTRY.

ANTINŒIA, in antiquity, were annual ſacrifices, and quinquennial games, in memory of Antinous the Bythinian.

ANTINOMIANS, or ANOMIANS, in church hiſtory, denote certain heretics, who firſt appeared about the year 1535, and ſo called becauſe they rejected the law as of no uſe under the goſpel diſpenſation, with other doctrines equally abſurd.

Moſt authors as well as lexicographers, date their origin from John Agricola, their leader, in 1538; but according to the moſt authentic records of hiſtory, I find this date an Anachroniſm, and the pretended founder of the ſect a ſtigma, on a wrong perſon.

ANTINOMY, in a general ſenſe, implies an oppoſition or contraſt to all laws; hence an outlaw is uſually ſtiled an antinomy.

ANTINOUS, in aſtronomy, implies the upper part of the conſtellation Aquila, or the eagle.

ANTIOCHIAN *Sect*, in literature, denotes the 5th branch of the ancient academies, which was founded by Antiochus, a cotemporary of Cicero's.

ANTIOPE, in mythology, the daughter of Micteus, debauched by Jupiter.

ANTIOCHIAN *Epocha*, in chronology, denotes a period for computing time from the proclamation of liberty, granted to the city of Antioch, about the time of the battle of Pharſalia.

ANTI-PÆDO-BAPTISTS, in the hiſtory of the Chriſtian church, denote thoſe ſectariſts who deny baptiſm to be ſufficient during an infantile ſtate, to be emolled in the faith of Chriſt.

ANTIPARALLELS, in geometry, imply thoſe lines which form the ſame angles, with two other lines, cutting them the contrary ways, to that of the parallel lines.

ANTIPATHY, in the natural order of the paſſions, implies an averſion of one body to another, in contradiſtinction to ſympathy.

Several authors endeavour to account for the antipathy between animals, by the following rule: As effluvia and ſpirituous ſteams proceed from the bodies of all creatures, ſome of which diſagree with others, they excite hatred and anger in each other.

In the modern philoſophic definition of ſyſtem, antipathy, with many other eſſential cauſes of animal nature, are explored for the purpoſes of the phyſiologiſt; but with what degree of certainty it is needleſs to remark, as the whole amounts to no more than a repelling power! Thus the hypotheſis falls to the ground, and the learned ranks with the unlearned, becauſe his doctrines can only be founded on principles of unerring truth; namely, that he acts, or performs, agreeably to the propenſities of nature, inculcated by habit: Thus, for inſtance, one man ſhrinks at the ſight of a reptile, whilſt another approaches it undiſturbed, merely becauſe the latter is well acquainted with its nature, whilſt the former never, probably, beheld it before, and in idea conceived an horror at ſuch an object, unſuitable to the emotions it ſhould have incited.

ANTIPATHY, in ethics, implies the contraſt that may be drawn between reaſon, or the action of the mind, and inclination, or the action of the body.

ANTIPATHY, in painting, or other fine arts, denotes the oppoſed quality of colours, or light and ſhade.

ANTIPASCHA, in church ritual, denotes the firſt Sunday after Eaſter, or Dominica in Albis.

ANTIPELARGIA, in ancient law, denotes the duty of children to provide for the age and infirmities of their parents.

ANTIPERISTALTIC, in anatomy, implies the motion of the inteſtines, contradiſtinguiſhed from that of the periſtaltic motion.

ANTIPERISTASIS, in philoſophy, implies an imaginary intention, or heightening of any quality by the oppoſition of its contrary; thus cold is ſaid to augment the heat of the fire; a doctrine which every philoſopher can readily refute.

ANTIPHONA, in muſic, denotes a kind of chant made in the Roman Catholic church. The antiphonæ were ſo named, becauſe in their origin, they were ſung with two choruſſes, which anſwered each other alternately, and the pſalms, and hymns ſung in the church were comprehended under this name.

At preſent the ſignification of this term may be defined, ſhort paſſages drawn from Scripture, which are applicable to the feaſt which is then celebrating, and which preceding, the pſalms and cautics direct their intonation: The name of Antiphona is alſo preſerved in ſome hymns ſung in honour of the bleſſed Virgin Mary.

ANTIPHERNA, in the Greek laws, denoted a marriage ſettlement, which is now denominated a jointure.

ANTIPHONARY, in church ſervice, implies all that part of divine worſhip, which requires the ſolemnity of harmony.

ANTIPHONY, in muſic, was a name which the ancient Greeks gave to that kind of ſymphony, which was performed by divers voices, or by different inſtruments to the octave or double octave, in oppoſition to that which was executed in ſingle uniſon, and which they called homophony.

ANTIPHRASIS, in rhetoric, denotes an ironical expreſſion, or mode of ſpeech contrary to the meaning of the words, as ſimply to ſay one thing and mean another.

ANTIPODES, in geography, denote thoſe inhabitants of the globe which live diametrically oppoſite to each other.

The antipodes lie under oppoſite meredians and oppoſite parallels; in the ſame degree of latitude but of oppoſite denominations, the one north and the other ſouth; their heat, cold, their length of days and nights, are alike, but the ſeaſons oppoſite, for the longeſt day with one is the ſhorteſt with the other, et vice verſa. For a further explanation of this term, ſee Syſtem of GEOGRAPHY.

ANTIPOPE, in the Romiſh church, implies, a perſon elected pope in irregular manner, in oppoſition to another.

ANTIPORTICO, in architecture, implies the porch or entrance into an edifice.

ANTIPROBABILISM, in ſcience, imports a poſition which admits of doubts, in contradiſtinction to that which admits of none.

ANTIPROBOLE, in law, implies a rhetorical figure, which denotes an admiſſion of a crime or what we modernly define pleading guilty.

ANTIPROPEMPTICON, in poetry, implies a farewell poem, previous to a long journey.

ANTIPSORA, in pharmacy, denotes a medicine, good againſt the itch.

ANTIPTOSIS, in rhetoric, ſignifies a figure, by which one caſe is put for another.

ANTIQUARE, in the Roman law, denoted much the ſame as a negative to a new ſtatute in our parliament, as it is implied a voice of diſſent to a new law, or rejecting its principles.

Hence obſolete laws in theſe days are called antiquare, or antiquated laws.

ANTIQUARIUM, in antiquity, denoted a chamber to keep antiquities in.

ANTIQUARY, implies a perſon who ſtudies and ſearches after monuments and remains of antiquity; as old medals, books, ſtatues, ſculptures, and inſcriptions; and, in general, all curious pieces that may afford any light into antiquity.

There was an ancient college of antiquarics erected in Ireland by Ollamh Fodhla, 700 years before Chriſt, for compoſing a hiſtory of that country: and to this, ſay the Iriſh hiſtorians, it is owing that the hiſtory and antiquities of that kingdom may be traced back beyond thoſe of moſt other nations.

There is a ſociety of antiquaries in London, and another in Edinburgh, incorporated by the king's charter.

ANTIQUARY is alſo uſed by ancient writers for the keeper of the antiquarium or cabinet of antiquities. This officer is otherwiſe called Archæota, or antiquary of a king, a prince, a ſtate, or the like.

ANTIQUATED, denotes ſomething obſolete, or out of date.

ANTIQUE, in a general ſenſe, denotes ancient; but the term is chiefly uſed by ſculptors, painters, and architects, to denote ſuch pieces of their different arts as were made by the ancient Greeks and Romans.

ANTIQUE is ſometimes contradiſtinguiſhed from ancient, which ſignifies a leſs degree of antiquity.

ANTIQUITIES, a term implying all teſtimonies, or authentic accounts that have come down to us of ancient nations.

Antiquities form a very extenſive ſcience, including, "an hiſtorical knowledge of the edifices, magiſtrates, offices, habiliments, manners, cuſtoms, ceremonies, worſhip, and other objects worthy of curioſity, of all the principal ancient nations of the earth."

ANTIQUITY ſignifies times, or ages long ſince paſt.

ANTIQUITY alſo denotes the works or monuments of antiquity.

ANTIQUITY likewiſe expreſſes the great age of a thing; and in this ſenſe we ſay the antiquity of a family, the antiquity of a kingdom, &c.

ANTIRRHINUM, ſnap-dragon, or calves-ſnout, a genus of the angioſpermia order, belonging to the didynamia claſs of plants; and in the natural method ranking under the 40th order, Perſonatæ. For the characters, ſee Syſtem of BOTANY. There are 14 ſpecies of the antirrhinum, 10 of which are natives of Britain, viz. the cymbalaria, or ivy-leaved toad-graſs; the elatine, or ſharp-pointed fluellin; the ſpurium, or round-leaved fluellin; the arvenſe, or corn blue toad-flax; the repens, or creeping toad-flax; the monoſpermum, or ſweet-ſmelling toad-flax: the linaria, or common yellow toad-flax; the minus, or leaſt toad-flax; the majus, or greater ſnap-dragon; and the orontium, or leaſt ſnap-dragon. The linnria is ſaid to be cathartic and diuretic.

ANTISAGOGE, in rhetoric, ſignifies a figure ſynonymous with conceſſion.

ANTISCII, denote people who live on different ſides of the equator, whoſe ſhadows at noon are projected oppoſite ways.

ANTISCORBUTICS, in pharmacy, are medicines good in ſcorbutic caſes.

ANTISEPTICS, an appellation given to ſuch ſubſtances as reſiſt putrefaction.

The following table from Dr. Pringle, exhibits a comparative view of the antiſceptic virtue of ſalts; the common ſea ſalt being reckoned equal to unity.

Sea-ſalt	1	Saline mixture	3
Sal gemmæ	1	Nitre	4
Tartar vitriolated	2	Salt of hartſhorn	4
Spiritus Mindereri	2	Salt of wormwood	4
Tartarus ſolubilis	2	Borax	12
Sal diureticus	2	Salt of amber	20
Crude ſal ammoniac	3	Alum	30

Some reſinous and other ſubſtances were found to be 12 times more antiſceptic than ſea ſalt; ſuch are myrrh, aſafætida, terra japonica, and aloes.

Two grains of camphor is equivalent to ſixty grains of that ſalt. An infuſion of a few grains of Virginian ſnake-root, in powder, exceeds twelve times its weight of ſea-ſalt. Camomile flowers have nearly the ſame extraordinary quality. The Jeſuits bark has it alſo. Beſides theſe, pepper, ginger, ſaffron, contrayerva-root, are twelve times more antiſeptic than ſea-ſalt.

Dried ſage, rhubarb, the root of the wild valerian, mint, angelica, ground ivy, ſenna, green tea, red roſes, wormwood, muſtard, and horſe-radiſh, were likewiſe found more antiſeptic than the ſtandard.

Antiſeptics are preſcribed in all putrid, malignant, and peſtilential caſes.

It is to be remarked, however, that different kinds of them are to be given in different diſeaſes, and even in different ſtages of the ſame diſeaſe. Thus, the bark is a ſpecific in a gangrene, when the veſſels are relaxed, and the blood reſolved or diſpoſed to putrefaction; but will fail, if the veſſels are too full, or the blood be too thick. With the ſame caution is the bark to be uſed in wounds, viz. chiefly in caſes of abſorbed matter, when it infects the humours, and brings on a hectic fever.

ANTISPASMODICS, in pharmacy, are medicines proper for the cure of ſpaſms and convulſions. Opium, balſam of Peru, and the eſſential oils of many vegetables, are the principal in this claſs of medicines.

ANTISPASTUS, in poetry, denotes a foot conſiſting of four ſyllables, the firſt and fourth ſhort, and the ſecond and third long.

ANTISTASIS, in oratory, implies a defence of an action from the conſideration that had it been omitted worſe would have enſued.

ANTISTES, or Antistæ, in antient and modern orders of divine worſhip, both Pagan and Jewiſh, as well as Chriſtian, denotes the heads of the church.

ANTISTIGMA, in grammar, implies the notation of a ſentence which requires tranſpoſition.

ANTISTŒCHON, in grammar, implies the uſing of one letter inſtead of another; as *olli* for *illi*.

ANTISTROPHE, in grammar, a figure by which two things mutually depending on one another, are reeiprocally converted; as, the ſervant of the maſter, the maſter of the ſervant.

Antistrophe, among lyric poets, denotes that part of a ſong and dance in uſe among the ancients, which was performed before the altar, in returning from weſt to eaſt; in oppoſition to ſtrophe.

ANTISYLLOGISM, in logic, inſers a contrary concluſion to that of another ſyllogiſm.

ANTITACTÆ, in church hiſtory, ſignify a branch of gnoſtics, who held, that God was good and juſt, but that a creature had created evil; and conſequently that it is our duty to oppoſe this author of evil, in order to avenge God of his adverſary.

ANTITHENAR, in anatomy, a name given to the adductor incicis.

ANTITHESIS, in rhetoric, implies a contraſt or oppoſition of words or ſentiments. Such is that of Cicero, in the ſecond Catilinarian: "On one ſide ſtands modeſty, on the other impudence; on one fidelity, on the other deceit; here piety, there ſacrilege; here continency, here luſt, &c."

Antithesis is ſometimes uſed for controverſy. In this ſenſe, we meet with antithetic method, antithetic diſcourſes, &c.

ANTITRAGUS Musculus, in anatomy, a muſcle of the ear.

ANTITRINITARIANS, thoſe who deny the Trinity, and teach that there are not three perſons in the Godhead.

Thus the Samoſatenians, who do not believe the diſtinction of perſons in God; the Arians, who deny the divinity of the word; and the Macedonians, who deny that of the Holy Spirit, are all properly Antitrinitarians.

Among the moderns, Antitrinitarians are particularly underſtood of Socinians, called alſo Unitarians.

ANTITYPE, a Greek word, properly ſignifying a type or figure correſpondent to ſome other type.

There are two places in the New Teſtament, viz. in the Epiſtle to the Hebrews, ix. 24. and in St. Peter, 1 Ep. iii. 21. where this word occurs, and its genuine import has been much controverted.

The former ſays, that "Chriſt is not entered into the holy places made with hands, which are αντιτυπα, the figures or antitypes of the true, now to appear in the preſence of God for us."

In the latter paſſage, the Apoſtle, ſpeaking of Noah's flood, and the deliverance only of eight perſons in the ark from it, ſays, Ω και ημας αντιτυπον νυν σωζει βαπτισμα, *baptiſm, being an antitype to that, now ſaves us; not putting away the filth of the fleſh, but the anſwer of a good conſcience towards God, &c.*

The meaning is, that righteouſneſs, or the anſwer of a good conſcience towards Cod, now ſaves us by means of the reſurrection of Chriſt, as formerly righteouſneſs ſaved thoſe eight perſons by means of the ark, during the flood.

Here it ſignifies a general ſimilitude of circumſtances; and the particle ω, *whèreunto*, refers, not to the immediate antecedent, υδατος, *water*, but to all that precedes.

Antitype, among the ancient Greek fathers, and in the Greek liturgy, is alſo applied to the ſymbols of bread and wine in the Sacrament. Hence it hath been argued, by many Proteſtants, that the Greeks do not really believe the doctrine of tranſubſtantiation; becauſe they call the bread and wine *antitypes*, αντιτυπα, q. d. figures, ſimilitudes; and this even after the conſecration.

ANTLER, in the manege, implies a ſtart or branch of a deer's attire.

Brow Antler, denotes the branch next the head; and

Bes Antler, the branch next above the brow-antler.

ANTLIA, in ancient mechanics, is ſuppoſed to be the ſame with our pump. Hence the phraſe, *in antliam condemnari*, according to the critics, denotes a kind of puniſhment, by which criminals were condemned to drain ponds, ditches, or the like.

ANTŒICI, in geography, thoſe inhabitants of the earth who live under the ſame meridian, and at the ſame diſtance from the equator; the one north, and the other ſouth.

They have the ſame longitude; and their latitude is alſo the ſame, but of a different denomination.

They are in the ſame ſemicircle of the meridian, but oppoſite in parallels. They have preciſely the ſame hours of the day and night, but oppoſite ſeaſons. If the antœici both turn their faces towards the equator, the ſtars and planets will riſe to me on the right hand, and to the other on the left.

ANTOMOSIA, in ancient law, denoted the oaths of the proſecutor and the delinquent in criminal caſes.

The former alledged on oath the whole of his charge, and the latter denied on oath either the whole or part of it; then the judges proceeded to conſider of both claims, the one of guilt and the other of innocence, and decided on the merirs by circumſtantial evidence.

ANTONIAN Waters, in the materia medica, a mineral ſpring of Germany, remarkably well taſted, and good againſt various complaints proceeding from the foulneſs of the blood.

ANTONOMASIA, implies a form of ſpeech, in which, for a proper name, is put the name of ſome dignity, office, profeſſion, ſcience, or trade; or when a proper name is put in the room of an appellative.

Thus a king is called, his Majeſty; a nobleman, his Lordſhip; a wiſe man, Solomon; and a grave man, Cicero. Hence the appellatives, an Engliſhman, Iriſhman, Frenchman, &c. as derivatives from their country, profeſſion, &c.

ANTOPHYLLUS, in botany, denotes the fruit of the clove tree.

ANTOSIANDRIANS, imply a ſect of rigid Lutherans, who oppoſe the doctrine of Oſiander relating to juſtification.

ANTRUM, among anatomiſts, denotes ſeveral cavities of the body: as the antrum high-morianum, or that in the maxillary or jaw bone; antrum pylori, or that at the bottom of the pylorus, &c.

ANUBIS, in mythology, a ſymbolical deity of the Egyptians who regarded as the faithful companion of Oſiris and Iſis. Temples and prieſts were conſecrated to him, and his image was borne in all religious ceremonies. He was repreſented with a dog's head; and frequently under the figure of a dog.

ANUS, in anatomy, ſignifies the lower extremity of the inteſtinum rectum, or orifice of the fundament.

ANVIL, implies a ſmith's utenſil, ſerving to place the iron on it, to be hammered or forged.

The face of the anvil, muſt be very flat and ſmooth, without flaws, and ſo hard that a file will not touch it.

At one end there is a pike, or beak-iron, for the rounding of hollow work. The whole is uſually mounted on a firm wooden block.

Forged anvils are better than thoſe of caſt work, and the beſt have the upper part made of ſteel.

AONIDES, in mythology, is one of the many appellations of the muſes; ſo called from Aonia, a part of ancient Bœotia.

AORASIA, or Aoritia, in antiquity, implies the inviſibility of the gods.

The opinion of the ancients was, that they never ſhowed themſelves face to face, but were known from their backs as they withdrew.

AORIST, or Aoristus, among grammarians, denotes a tenſe peculiar to the Greek and French languages, comprehending all the tenſes.

AORISTIA, in the ſceptic philoſophy, denotes that ſtate of the mind in which we neither aſſert or deny any thing poſitively, but only ſpeak of things as appearing to us in ſuch a manner.

The aoriſtia is one of the great points of ſcepticiſm, to which the philoſophers of that denomination had continual recourſe by way of explication, or ſubterfuge.

AORTA, in anatomy, implies the great artery which riſes immediately from the left ventricle of the heart, and is from thence diſtributed to all parts of the body.

It is divided into two grand trunks, diſtinguiſhed by the epithets aſcending and deſcending.

AOUTA, in commercial diſtinctions, is the name of the paper mulberry-tree at Otaheite, in the South Sea, from which a cloth is manufactured, that is worn by the principal inhabitants.

APACHES, denote a people of New Mexico in North America. They are brave, reſolute, and warlike, fond of liberty, and the inveterate enemies of tyranny and oppreſſion.

APÆDUSIA, in literature, denotes an ignorance of ſcience. The term apædeutæ was particularly uſed among the French in the time of Huet: when the men of wit at Paris were divided into two factions, one called by way of reproach apædeutæ, and the others eruditi.

The apædeutæ are repreſented by Huet, as perſons who, finding themſelves either incapable, or unwilling to undergo a ſevere courſe of ſtudy in order to become truly learned, conſpired to decry learning, and turn the knowledge of antiquity into ridicule, thus making a merit of their own incapacity.

The apædeutæ in effect were the men of pleaſure; the eruditi the men of ſtudy.

APAGMA, in ſurgery, denotes the thruſting of a bone or joint out of its proper place or ſocket.

APAGOGE, in logic, ſynonymous with Abduction.

Apagoge, in the Athenian law, the carrying a criminal taken in the fact to the magiſtrate. If the accuſer was not able to bring him to the magiſtrate it was uſual to take the magiſtrate along with him to the houſe where the criminal lay concealed, or defended himſelf.

Apagoge, in mathematics, denotes a progreſs from one propoſition to another.

APAGOGICAL Demonstration, in mathematical ſciences, implies an indirect way of proof, by ſhewing the abſurdity of the contrary.

APANAGE, or Appennage, in the French laws, are lands aſſigned by a ſovereign for the ſubſiſtence of his younger ſons, which revert to the crown upon the failure of male iſſue in that branch to which the lands are granted.

APANTHROPY, in medicine, a love of ſolitude, and an averſion to the company of mankind.

Apanthropy is by ſome reckoned among the ſymptoms, by others among the ſpecies or degrees, of melancholy; and alſo paſſes for an ill indication in lencophlegmatic caſes.

APARINE, in botany, a ſynonyme of the utricularia and ſeveral other plants.

APARITHMESIS, in rhetoric, denotes the anſwer to the protaſis or propoſition itſelf. Thus, if the protaſis be, *Appellandi tempus nomerat*, the aparithmeſis, is *At tecum anno plus vixi*. It ſometimes implies a circum locum.

APARTISMENUS, in ancient poetry, an appellation given to a verſe, which comprehended an entire ſentence in itſelf.

This is ſometimes alſo written, apartemenus, i. e. ſuſpended, as not needing any following verſe.

APARTMENT, in a legal ſenſe, implies that part of an houſe containing the neceſſary conveniencies to reſide in, as a dwelling in every reſpect fully complete.

APATHY, among the ancient philoſophers, implied an utter privation of paſſion, and an inſenſibility of pain.

The ſtoics affected an entire apathy: they conſidered it as the higheſt wiſdom to enjoy a perfect calmneſs or tranquility of mind, incapable of being ruffled by either pleaſure or pain.

The primature chriſtians adopted the term apathy to expreſs a contempt of all earthly concerns, ſuch as the goſpel preſcribes.

APATURIA, in antiquity, a ſolemn feaſt celebrated by the Athenians in honour to Bacchus.

APAULIA, in antiquity, implies the third day after marriage. It was thus called, becauſe the bride, returning to her father's houſe, lodge apart from the bridgroom.

APE, in zoology is the general Engliſh name of a very numerous race of animals, the natural hiſtory of which is given at large under the article Simia: comprehending apes, monkeys, and baboons.

Sea Ape, a name given by Steller to a marine animal he ſaw on the coaſt of America, which he deſcribes as follow: "The head appeared like that of a dog, with ſharp and upright ears, large eyes, and with both lips bearded: the body round and conoid; the thickeſt part near the head: the tail forked; the upper lobe the longeſt: the body covered with thick hair, grey on the back, rediſh on the belly. It ſeemed deſtitute of feet. It was extremely wanton, and played a multitude of monkey-tricks. It ſometimes ſwam on one ſide, ſometimes on the other ſide of the ſhip, and gazed at it with great admiration. It made ſo near an approach to the veſſel, as almoſt to be touched with a pole; but if any body moved, it inſtantly retired. It would often ſtand erect for a conſiderable ſpace, with one-third of its body above water; then dart beneath the ſhip, and appear on the other ſide; and repeat the ſame thirty times together. It would frequently ariſe with a ſea-plant, not unlike the bottle-gourd, toſs it up, and catch it in its mouth, playing with it numberleſs fantaſtic tricks."

APEEK, in the marine, implies, perpendicular to the anchor: a ſhip is ſaid to be in this ſituation when the cable is drawn ſo tight into the bow as to bring her directly over the anchor, ſo that the cable bears right down from the ſhip's ſtem.

APELLA, among phyſicians, is a name given to thoſe whoſe prepuce is either wanting or ſhrunk, ſo that it can no longer cover the glans.

APENE, in antiquity, a kind of chariot wherein the images of the gods were carried in proceſſion on certain days, attended with a ſolemn pomp, ſongs, hymns, and dancing.

APENNIS, in ancient law, ſignified a record given to a perſon who had loſt deeds, papers, or writings, by fire or other caſualty; in which caſe the record bore teſtimony of the event, ſo that the original writings could be legally diſpenſed with.

APEPSIA, or Apepsy, in medical language, implies indigeſtion. A mixture of muſtard-ſeed, with the columbo root, is of admirable utility in complaints of this kind; particularly where acidity and flatulence prevail much in the primæ viæ.

APER, implies a ſynonyme of the boar, in zoology; the faber or doree, in ichthyology, and to the tajacu, in natural hiſtory.

APEREA, in zoology, is a ſmall ſpecies of the American rabbit, little bigger than a rat.

APERIENS *Palpebram Rectus*, in anatomy, implies the muſcle of the eye-lid.

APERIENTS, in the materia medica, are ſuch medicines as facilitate the circulation of the humours, by removing obſtructions.

The five aperient roots of the ſhops are ſmallage, fennel, aſparagus, parſley, and butcher's broom.

APERNE, in antiquity, ſynonymous with Apene.

APERTIONS, in architecture, ſignify every opening in a building, and are ſynonymous with apertures.

APERTURA Tabularum, in law, denotes the breaking open or unſealing a laſt will and teſtament, after the deceaſe of the teſtator.

APERTURE, implies the opening or cleft in any continuous ſubject.

Aperture, in geometry, is the ſpace between two right lines which meet in a point and form an angle.

Aperture, in optics, is a round hole in a turned bit of wood or plate of tin, placed within the ſide of a teleſcope or microſcope, near to the object-glaſs, by means of which more rays are admitted, and a more diſtinct appearance of the object is obtained.

Apertures, in architecture, ſignify doors, windows, chimneys, &c.

APETALOSE, or Apetalous, among botaniſts, is an appellation given to ſuch plants as have no flower-leaves.

APEUCTICTIC, in divine poetry, implies an hymn to the Deity, to avert ſome threatened evil.

APEX is the vertex or ſummit of any thing, whoſe top is of a globular form.

Apex, in antiquity, denotes the creſt of a helmet, alſo a kind of cap worn by the Flamens.

Apex, among grammarians, denotes the mark of a long ſyllable, falſely called a *long accent*.

APHANES, in botany, is a genus of the monogynia order, belonging to the tetrandia claſs of plants; and in the natural method ranking under the 35th order, Senticoſæ. The eſſential characters are theſe: the calyx is divided into eight parts; there is no corolla; the ſeeds are two, and naked. There is only one ſpecies, the arvenſis or parſley-piert, a native of Britain. It is extremely common in corn-fields.

APHASIA, in the ſceptic philoſophy, denotes a ſtate of doubt, in which a perſon not knowing what to determine on, it is beſt for him to be ſilent.

In this ſenſe, aphaſia ſtands oppoſed to phaſis, under which are included both aſſertion and negation.

APHÆRESIS, in grammar, ſignifies a figure, by which a letter or ſyllable is cut off from the beginning of a word. Thus *ciconio*, by aphæreſis, is written *conia*; *contemnere*, *temnere*; *omittere*, *mittere*, &c. and contradiſtinguiſhed from a retrenchment at the end of a word, which is called an apocope.

Aphæresis, in medicine, denotes a neceſſary removal of ſomething that is noxious. In ſurgery, if ſignifies an operation by which ſomething ſuperfluous is taken away.

APHEBA, in rhetoric, implies a ſimplicity of diction in a diſcourſe.

APHELIUM, or Aphelion, in aſtronomy; is that point in any planit's orbit, in which it is fartheſt diſtant from the ſun, being that end of the greater axis of the elliptical orbit of the planet moſt remote from the focus where the ſun is.

APHERNOUSLI, in natural hiſtory, a trivial name for the wild Alpinian pine.

APHETERIA, in ancient military art, an engine to conduct the battering ram in beſieging a fortreſs.

APHILANTHROPY, in phyſic, denotes a ſpecies of melancholy inſanity.

APHIOCEM, in pharmacy, implies a ſleeping doſe, previous to an operation of ſome danger on the human body. It alſo implies a kind of vegetable ſyrup drawn from the buds of trees by the Arabs, which has much the ſame intoxicating quality of opium.

APHIS, in zoology, the puceron, vine-fretter, or plant-louſe, a genus of inſects belonging to the order of inſecta hemiptera.

The roſtrum or beak of the aphis is inflected; the antennæ or feelers are longer than the thorax; the wings four, erect, or are wanting; the feet are of the ambulatoy kind; and the belly often ends in two horns, from which is ejected that moſt delicate juice called honey-dew.

There are 33 ſpecies of the aphis, all of them inhabitants of particuiar plants, from which their trivial names are taken; as, aphis ribis, ulmi, roſæ, &c.

Linnæus ſays that there ſeem to be a greater variety of plants producing aphides than there are different ſorts of this inſect.

The plum-tree has two ſorts very diſtinct from each other: one of a yellowiſh green the other of a bluiſh green, amelled with white, and the ſhape more oblong.

On the gooſeberry and currant buſhes the ſame aphides may be found; but each of theſe is inhabited by two very different ſpecies: one of a duſky green, with a ſhort plump body; the other of a paler green the body more taper, and tranſverſely wrinkled.

The roſe-tree, ſupports not leſs than three diſtinct ſpecies: the largeſt is of a deep green, the ſecond ſort is of a paler green, and the third ſort is of a pale red.

The extraordinary nature of theſe inſects have for ſome time paſt juſtly excited the wonder and attention of naturaliſts.

In a letter from the celebrated Mr. Trembley to Mr. Bonnet, dated at the Hague, the 27th January 1741, he thus expreſſes himſelf: "I formed, ſince the month of November, the deſign of rearing ſeveral generations of ſolitary pucerons, in order to ſee if they would all equally bring forth young. In caſes ſo remote from uſual circumſtances, it is allowed to try all ſorts of means; and I argued with myſelf, Who knows, but that one copulation might ſerve for ſeveral generations? This "*who knows*," to be ſure, was next to avouching nothing; but as it came from Mr. Trembley, it was ſufficient to perſuade Mr. Bonnet that he had not gone far enough in his inveſtigation. If the fecundity of aphides was owing to the ſecret copulation ſuggeſted by Mr. Trembley; this copulation ſerved at leaſt five or more ſucceſſive generations. Mr. Bonnet therefore reared to the amount of the tenth generation of ſolitary aphides, and had the patience to keep an account of the days and hours of the births of each generation. In ſhort, it was diſcovered, That they are really diſtinguiſhed by ſexes: that there are males and females amongſt them, whoſe amours are the leaſt equivocal of any in the world: that the males are produced only in the tenth generation, and are but few in number; that theſe, ſoon arriving at their full growth, copulate with the females; that the virtue of this copulation ſerves for ten generations; that all theſe generations, except the firſt (from the fecundated eggs) are produced viviporous; and all the individuals are females, except thoſe of the laſt generations, among whom, as we have already obſerved, ſome males make their appearance, to lay the foundations of a freſh ſeries. Theſe circumſtances have been confirmed by other naturaliſts. In particular, we have a curious and accurate detail of them by Dr. Richardſon of Rippon, in the Philoſophical Tranſactions, Vol. XI. Art. 22, an extract of which we ſhall here inſert, in order to give the reader as full an inſight into the nature of theſe ſingular inſects, as can be done by a mere detail of facts in themſelves utterly unaccountable.

"The great variety of ſpecies which occur in the inſects now under conſideration, may make an enquiry into their particular nature, ſeem not a little perplexed; having them, however, ſkilfully reduced under their proper genus, the difficulty is by this means conſiderably diminiſhed. All the inſects comprehended under any diſtinct genus, we may reaſonably ſuppoſe to partake of one general nature; and, by diligently examining any of the particular ſpecies, may thence gain ſome inſight into the nature of all the reſt. With this view I have choſen, out of the various ſorts of aphides, the largeſt of thoſe found on the roſe-tree; not only as its ſize makes it the more conſpicuous, but as there are few others of ſo long a duration. This ſort, appearing early in the ſpring, continues late in the autumn; whilſt ſeveral are limited to a much ſhorter term, in conformity to the different trees and plants from whence they drew their nouriſhment.

1. "If at the beginning of February the weather happens to be ſo warm as to make the buds of the roſe-tree ſwell and appear green; ſmall aphides are frequently to be found upon them, not larger than the young ones in ſummer when firſt produced. But there being no old ones to be found at this time of the year, which in ſummer I had obſerved to be viviparous, I was formerly not a little perplexed by ſuch appearances, and almoſt induced to give credit to the old doctrine of equivocal generation. That the ſame kind of animal ſhould at one time of the year be viviparous, and at another time oviparous, was an opinion I could then by no means entertain. This, however, frequent obſervation has at laſt convinced me to be fact; having found thoſe aphides, which appear early in the ſpring, to proceed from ſmall black oval eggs which were depoſited on the laſt years ſhoots in autumn: though, when it happens that the inſects make too early an appearance, I have obſerved the greateſt part to ſuffer from the ſharp weather that uſually ſucceeds, by which means the roſe-trees are ſome years in a manner freed from them.

"Thoſe which withſtand the ſeverity of the weather ſeldom come to their full growth before the month of April; at which time they uſually begin to breed, after twice caſting off their exuviæ or outward covering. It appears then that they are all females, which produce each of them a very numerous progeny, and that without having intercourſe with any male inſect. As I obſerved before, they are viviparous; and what is equally uncommon, the young ones all come into the world backwards. When they firſt come from the parent, they are enveloped by a thin membrane, having in this ſituation the appearance of an oval egg; which, I apprehend, muſt have induced Reaumur to ſuſpect that the eggs diſcovered by Bonnet were nothing more than mere abortions. Theſe egg-like appearances adhere by one extremity to the mother; while the young ones contained in them extend the other; by that means gradually drawing the ruptured membrane over the head and body to the hind feet. During this operation, and for ſome time after, by means of ſomething glutinous, the fore part of the head adheres to the vent of the parent. Being thus ſuſpended in the air, it ſoon frees itſelf from the membrane in which it was confined, and, after its limbs are a little ſtrengthened, is ſet down on ſome tender ſhoot, and then left to provide for itſelf.

2. "In the ſpring months, there appear on the roſe-trees but two generations of aphides, including thoſe which immediately proceed from the laſt year's eggs; the warmth of the ſummer adds ſo much to their fertility, that no leſs than five generations ſucceed one another in the interval. One is produced in May, which caſts off its covering; while the months of June and July each ſupply two more, which caſt off their covering three or four times, according to the different warmth of the ſeaſon. This frequent change of the outward covering is the more extraordinary, as it is the ofteneſt repeated when the inſects come the ſooneſt to their growth; which I have ſometimes obſerved to happen in ten days, where warmth and plenty of nouriſhment have mutually conſpired. From which conſiderations I am thoroughly convinced that theſe various coverings are not connate with the inſect; but that they are, like the ſcarf-ſkin, ſucceſſiively produced.

"Early in the month of June, ſome of the third generation which were produced about the middle of May, after caſting off their laſt covering, diſcover four erect wings, much longer than their bodies: and the ſame is obſervable in all the ſucceeding generations, which are produced during the ſummer months; without, however, diſtinguiſhing any diverſity of ſex, as is uſual in ſeveral other kinds of inſects. For ſome time before the aphides come to their full growth, it is eaſy to diſcover which of them will have wings, by a remarkable fullneſs of the breaſt, which, in the others, is hardly to be diſtinguiſhed from the body. When the laſt covering is rejected, the wings, which were before folded up in a very narrow compaſs, gradually extend themſelves in a moſt ſurpriſing manner, till their dimenſions are at laſt very conſiderable. But theſe winged ones have the peculiarity, that the number of them does not ſeem ſo much to depend on their original ſtructure, as on the quantity or quality of the nouriſhment with which they are ſupplied: it being frequently obſerved, that thoſe on a ſucculent ſhoot have few or none with wings among them, while others of the ſame generation, on a leſs tender branch, are moſt of them winged; as if only the firſt rudiments of wings were compoſed in the former, while nature thought proper to expand them in the latter, that they might be more at liberty to ſupply their wants.

"The increaſe of theſe inſects in the ſummer-time is ſo very great, that, by wounding and exhauſting the tender ſhoots, they would frequently ſuppreſs all vegetation, had they not many enemies which reſtrain them. To enumerate the variety of other inſects that in their worn and fly ſtate are conſtantly deſtroying them, would exceed the bounds of the preſent deſign: there is one however, ſo ſingular in the manner of executing its purpoſe, that I cannot paſs by it without ſome further notice. This is a very ſmall black ichneumon fly, with a ſlender body and very long antennæ, which darts its pointed tail into the bodies of the aphides, at the ſame time depoſiting an egg in each. This egg produces a worm, which feeds upon the containing inſect till it attains its full growth; when it is uſually changed to that kind of fly from whence it came. In this, however, it is ſometimes prevented by another ſort of ſmall black fly, which wounds this worm through its pearl-like habitation; and by laying one of its eggs therein, inſtead of the former fly, produces its own likeneſs. I muſt, however, further obſerve, notwithſtanding theſe inſects have many enemies, they are not without friends; if we may conſider thoſe as ſuch who were very officious in their attendance, for the good things they expect to reap thereby. The ant and the bee are both of this kind, collecting the honey in which the aphides abound; but with this difference, that the ants are conſtant viſitors, the bee only when flowers are ſcarce. To which let me alſo add, that the ants will ſuck in the delicious nectar while the aphides are in the act of diſcharging it from the anus; but the bees only collect it from the leaves on which this honey-dew has fallen.

3. " In the autumn I find three more generations of aphides to be produced; two of which make their appearance in the month of Auguſt, and the third uſually appear before the middle of September. As the two firſt differ in no reſpect from thoſe which we meet with in ſummer, it would be waſting time to dwell any longer upon them; but the third, differing greatly from all the reſt, demands our giving it a more ſerious attention. Though all the aphides which have hitherto appeared were females, in this tenth generation are found ſeveral male inſects; not that they are by any means ſo numerous as the females, being only produced by a ſmall number of the former generation. To which I muſt further add, that I have obſerved thoſe which produce males, previouſly to have produced a number of females; which in all reſpects reſembling thoſe already deſcribed, I ſhall decline taking into any further conſideration.

" The females have at firſt altogether the ſame appearance with thoſe of the former generations: but in a few days their colour changes from a green to a yellow, which is gradually converted into an orange colour before they come to their full growth. They differ likewiſe in another reſpect, at leaſt from thoſe which occur in the ſummer, that all thoſe yellow females are without wings. The male inſects are, however, ſtill more remarkable, their outward appearance readily diſtinguiſhing them from the females of this and all other generations. When firſt produced, they are not of a green colour like the reſt, but of a reddiſh brown; and have afterwards, when they begin to thicken about the breaſt, a dark line along the middle of the back. Theſe male inſects come to their full growth in about three weeks time, and then caſt off their laſt covering; the whole inſect being, after this operation, of a bright yellow colour, the wings only excepted. But after this they ſoon change to a darker yellow, and in a few hours to a very dark brown; if we except the body, which is ſomething lighter coloured, and has a reddiſh caſt. They are all of the winged ſort; and the wings, which are white at firſt, ſoon become tranſparent, and at length appear like very fine black gauze.

" The males no ſooner come to maturity than they copulate with the females; in which act they are readily diſcovered, as they remain in conjunction for a conſiderable time, and are not eaſily diſturbed. The commerce between them continues the whole month of October, and may be obſerved at all times of the day, though I have found it moſt frequent about noon: eſpecially when the weather is moderately warm, and the ſun overcaſt. The females, in a day or two after their intercourſe with the males, I have obſerved to lay their eggs; which they uſually do near the buds, when they are left to their own choice. Where there are a number crowded together, they of courſe interfere with each other; in which caſe they will frequently depoſite their eggs on others parts of the branches, or even on the ſpines with which they are beſet."

APHLASTUM, in the antient navigation, was a wooden ornament, ſhaped like a plume of feathers, faſtened on the gooſe or ſwan's neck, uſed by the ancient Greeks in the heads of their ſhips.

It ſeems alſo to have had this further uſe, viz. by the waving of a party-coloured ribband faſtened to it, to indicate from what quarter the wind blew.

APHONIA, among phyſicians, ſignifies a ſuppreſſion or total loſs of voice.

APHORISM, implies a maxim or principle of ſcience; which comprehends a great deal in a few words. The term is chiefly uſed in medicine and law.

APHRACTI, in the ancient military art, denotes open veſſels without decks or hatches, furniſhed only at head and ſtern with croſs planks, on which the men ſtood to fight.

APHRODISIA, in antiquity, denotes feſtivals kept in honour of Venus, by the Cyprians.

APHRODISIACS, among phyſicians, denotes medicines which create an inclination to venery.

APHRODISIUS, in chronology, denotes the 11th month of the Bythinian year, commencing on the 25th of July.

APHRODITA, in zoology, is an inſect of the order of vermes molluſca, the body of which is oval, with many ſmall protuberances on each ſide, which ſerve as ſo many feet: the mouth is cylindrical at one end of the body, and capable of being retracted, with two briſtly tentacula.

There are four ſpecies, viz. 1. The aculeata, or ſea-mouſe, with 32 tentacula or feet, an inhabitant of the European ſeas, and are often found in the belly of the cod-fiſh. 2. The ſcabra, of an oblong ſhape, ſcabrous on the back, with 20 tentacula; inhabits the Belgic ſea. 3. The ſquamata, with 24 feet, and ſcaly on the back; inhabits the European ocean. 4. The imbricata, is very like the former, only its ſcales are more glabrous; inhabits the Northern ocean.

APHRODITARIUM, in pharmacy, denotes drying medicines, compounded of dry qualities, and conſequently taken in powders.

APHRODITE, in mythology, one of the names of Venus, derived from *αφρος*, *froth*, becauſe ſhe is ſuppoſed to have been produced from the froth of the ſea.

APHRONITRE, in natural hiſtory, is a name given by the ancients to a particular kind of natrum.

APHROSELENOS, in natural hiſtory, a ſynonyme of Selenites, or lapis ſpecularis.

APHTHÆ, in medicine, imply ſmall ſuperficial ulcers ariſing in the mouth.

APHUA *Cobites*, in ichthyology, the ſame with ſea-leach.

APHYLLANTHES, in botany, a leafleſs flower, or blue montpellier pink, a genus of the monogynia order, belonging to the hexandria claſs of plants; and in the natural method ranking under the 5th order, Tetrapetaloidæ. In character it is the ſame as the juncus, or ruſh, except a calyx of ſix petals.

There is only one ſpecies, the Monſpelienſes, a native of France. The ſtalk is round, ſmooth, without a joint or knot, naked, and tolerably firm; at its top ſtands a ſingle and very beautiful blue flower, ariſing from a kind of compound imbricated cup.

APIARIA, in entomology, ſignifies a ſpecies of the attelabus, or two-winged autumn parſley fly.

APIARY, denotes a place where bees are kept.

APIASTELLUM, in botany, is ſynonymous with baum and bryony.

APIASTER, in ornithology, is the trivial name of a ſpecies of the merops.

APIASTRUM, in botany, was a ſynonyme with the ancients for good and evil plants, e. g. the balm as good, and water crowfoot, as evil. The one was of an healing quality, and the other deadly poiſon.

APICES, in botany, the ſame with Antheræ.

APIOS, the botanic name for the whole ſpecies of ſpurge: alſo a denomination given to the glycine of Linnæus.

APIS, in aſtronomy, implies a ſouthern conſtellation, containing four ſtars, two of which are of the 4th, and two of the 5th magnitude.

APIS, or BEE, in zoology, is a genus of inſects belonging to the order of inſecta hymenoptera. The mouth is furniſhed with two jaws, and a proboſcis infolded in a double ſheath; the wings are four, the two foremoſt covering thoſe behind when at reſt: in the anus or tail of the females and working bees there is a hidden ſting.

They are diſtinguiſhed into ſeveral ſpecies, each of which has its peculiar genius, talent, manners, and diſpoſition. Variety prevails in the order of their architecture, and nature of their materials.

Some live in ſociety, and ſhare the toils; ſuch are the common bee and drone. Others dwell and work in ſolitude, building the cradles of their families; as the leaf-cutter bee does with the roſetree leaf; the upholſterer with the gaudy tapeſtry of the corn-roſe; the maſon-bee with a plaſter, the wood piercer with ſawduſt. All are employed in their little hermitage, with the care of providing for the wants of their poſterity. The ſpecies enumerated by Linnæus are 55; the following of which are the moſt remarkable: viz.

1. The floriſomnis, or black bee with a cylindrical incurvated belly, having too tooth-like protuberances at the anus, and a kind of prickles on the hind-legs. This bee ſleeps in flowers.

2. The dentata, or ſhining green bee, with black wings, and a kind of teeth on the hind thighs.

3. The variegata: the breaſt and belly are variegated with white and black ſpots; the legs are of an iron colour.

4. The roſtrata is diſtinguiſhed by the upper lip being inflected and of a conical ſhape, inveſted with bluiſh belts. They build their neſts in high ſandy grounds, and there is but one young in each neſt.

5. The ferruginea, or ſmooth black bee, with the feelers, mouth, belly, and feet, of an iron colour.

6. The carioſa is a yellowiſh hairy bee; and the feet and front are of a bright yellow colour. It builds in the rotten trees of Europe.

7. The braſilianorum, or pale-red hairy bee, with the baſis of the thighs black. It is very large covered with a teſtaceous ſkin; a native of America.

8. The lapidaria, or red hairy bee, with a yellow anus, builds in holes of rocks.

9. The terreſtris is black and hairy, with a white belt round the breaſt, and a white anus: it builds very deep in the earth.

10. The violacea is a red hairy bee, with bluiſh wings; a native of Europe.

The violacea is ſaid to perforate trees, and hollow them out in a longitudinal direction; and build their cells at the bottom of theſe holes.

11. The muſcorum, or yellow hairy bee with a white belly, builds in moſſy grounds. The ſkill diſplayed by theſe builders is admirable.

12. The centuncularis, leaf-cutter, or black bee, having its belly covered with yellow down; makes its neſt of leaves curiouſly plaited in the form of a matt or quilt. There are ſeveral varieties of theſe, all equally induſtrious.

13. The mellifica, or domeſtic honey-bee; the particulars concerning this valuable ſpecies are ſo numerous and intereſting that they are given in due form under the article BEE.

In the Philoſophical Tranſactions, N°. 172, there is an account of a ſpecies of honey-bee found in America, very different in form and manners from the common European bee.

Their combs are compoſed of a ſeries of ſmall bottles or bladders of wax, of a duſky brown or blackiſh colour; and each of theſe is much of the ſize and ſhape of a Spaniſh olave.

They hang together in cluſters, almoſt like a bunch of grapes, and are ſo contrived, that each of them has its aperture, while the bees are at work upon it; but as ſoon as it is filled with honey, this aperture is cloſed, and they leave it, and go to work upon another veſſel. They are ſagacious in chooſing the moſt ſecure retreats, becauſe their honey is ſo delicious a bait, that they are hunted after by many animals; having no power to defend themſelves, having no ſtings as our bees have.

APITES *Vinum*, in commerce and huſbandry, implies perry, or pear wine, of which it is a ſynonyme.

APIUM, parſley, a genus of the digynia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 45th order, Umbellatæ. The fruit is of an oval ſhape, and ſtreaked; the involucrum conſiſts of one leaf; and the petals are inflected. There are only two ſpecies of apium; the petroſelinum, or common parſley, a native of Sardinia; and the graveolens, or ſmallage, a native of Britain: the culture of both which are well known.

The root of parſley is one of the five aperient roots, and in this intention is ſometimes made an ingredient in apozems and diet-drinks.

The ſeeds are an ingredient in the electuary of bay-berries.

Common parſley is reckoned an effectual cure for the rot in ſheep, provided they are fed with it twice a week for two or three hours each time.

APIVORUS, in ornithology, is a ſynonyme of a ſpecies of falco.

APLUDA, a genus of the monœcia order, belonging to the polygamia claſs of plants; and in the natural method ranking under the 4th order Gramina. For the characters, ſee Syſtem of BOTANY.

There are three ſpecies of apluda, viz. the mutica, ariſtata, and zengites, all natives of the Indies.

APLUSTRA, or APLUSTRE, in the marine, implied the antique method of decorating the ſhips head with a ſhield, flag, or enſign, according to the name it bore, whether male or female.

APNŒA, in medical language, implies a ſudden ſuffocation, or loſs of breath by noxious vapour, or a paroxiſm.

APOBATERION, in antiquity, implies a valedictory ſpeech made by a perſon on departing out of his own country, and addreſſed to his friends or relations.

APOBATHRÆ, in antiquity, were ſtep ladders to get on ſhipboard.

APOBEE, in botany, expreſſes the Guinea phraſe for the corn marygold.

APOBOMIOI, in ancient rites, implied a ſacrifice offered on the earth, without raiſing an altar.

APOCALYPSE, REVELATION, the name of one of the ſacred books of the New Teſtament, containing revelations concerning ſeveral important doctrines of Chriſtianity. The word is Greek, and derived from αποκαλυπτω, to *reveal* or *diſcover*.

This book, according to Irenæus, was written about the year 96 of Chriſt, in the iſland of Patmos, whither St. John had been baniſhed by the emperor Domitian.

The Greek fathers called the author St. John the Divine by way of eminence, to diſtinguiſh him from the other evangeliſts.

This ſacred book conſiſts of twenty-two chapters. The three firſt are an inſtruction to the biſhops of the ſeven churches of Aſia Minor; the fifteen following chapters contain the perſecutions which the church was to ſuffer from the Jews, heretics, and Roman emperors, Next, St. John propheſies of the vengeance of God, which he will exerciſe againſt thoſe perſecutors, the Roman empire, and the city of Rome; which, as the Proteſtants ſuppoſe, he deſcribes under the name of Babylon, the great whore, ſeated upon ſeven hills. In the laſt place, the 19th, 20th, 21ſt, and 22d chapters, deſcribe the triumph of the church over its enemies, the marriage of the lamb, and the happineſs of the church triumphant.

Sir Iſaac Newton in ſpeaking of this ſacred book, obſerves: "It is a part of this propheſy, that it ſhould not be underſtood before the laſt age of the world; and therefore it makes for the credit of the propheſy, that it is not yet underſtood, The folly of interpreters has been to foretel times and things by this propheſy, as if God deſigned to make them prophets. By this raſhneſs they have not only expoſed themſelves, but brought the prophecy alſo into contempt. The deſign of God was much otherwiſe: he gave this and the prophecies of the Old Teſtament, not to gratify mens curioſities, by enabling them to foreknow things: but that, after they were fulfilled, they might be interpreted by the events; and his own providence, not the interpreters, be then maniſeſted thereby to the world. And there is already ſo much of the prophecy fulfilled, that as many as will take pains in this ſtudy, may ſee ſufficient inſtances of God's providence."

APOCARITES, in eccleſiaſtical hiſtory, denotes the opinion of ſeveral ſectaries, who ſuppoſed the human ſoul is derived immediately from the ſubſtance of the Deity.

APOCATASTASIS, in aſtronomy, implies the return of a planet to the point from which its orbit commences.

In medicine, it denotes the ſubſiding of a diſeaſe or complaint.

In law, it denotes to reſtore property to the lawful proprietor.

In divinity, it denotes the propitiation that Chriſt made to God his father for the redemption of the world by his death.

APOCATHARSIS, in pharmacy, denotes an expurgation.

APOCHA, in law, denotes a receipt for monies paid, to ſtand as a voucher for the debtor againſt the creditor for a ſettlement of accounts.

APOCOPE, among grammarians, is a figure which cuts off a letter or ſyllable from the end of a word; as ingeni for ingenii.

APOCRISARIUS, in eccleſiaſtical antiquity, denotes a ſort of reſident in an imperial city, in the name of a foreign church or biſhop, whoſe office was to negociate, as proctor, at the emperor's court, in all eccleſiaſtical cauſes in which his principals might be concerned.

The title and quality of apocriſary became at length appropriated to the Pope's agent, or Nuncio, as he is now called; who reſided at Conſtantinople, to receive the Pope's diſpatches, and the emperor's anſwers.

APOCRISIS, in literary productions, denotes an anſwer, be the cauſe of enquiry what it may.

APOCRUSTICS, in medicine, is the ſame with repellents.

APOCRYPHA, or APOCRYPHAL BOOKS, denote ſuch books as are not admitted into the canon of Scripture, being either not acknowledged as divine, or conſidered as ſpurious.

When the Jews publiſhed their ſacred books, they gave the appellations of canonical only to ſuch as they then made public, and ſuch as were ſtill retained in their archives they called apocryphal, for no other reaſon than they were not public; ſo that they might be really ſacred and divine, though not denominated as ſuch.

Thus, in reſpect of the Bible, all books were called apocryphal which were not inſerted in the Jewiſh canon of Scripture.

The Proteſtants do not only reckon thoſe books to be apocryphal which are eſteemed ſuch in the church of Rome, as the prayer of Manaſſeh king of Judath, the third and fourth books of Eſdras, St. Barnabas's epiſtle, the book of Hermos, the addition at the end of Job, and the 151ſt Pſalm; but alſo Tobit, Judith, Eſter, the book of Wiſdom, Jeſus the ſon of Sirach, Baruch the prophet, the Song of the Three Children, the hiſtory of Suſannah, the hiſtory of Bell and the Dragon, and the firſt and ſecond books of Maccabees.

It is now pretended that theſe books were not received by the Jews, or ſo much as known to them. None of the writers of the New Teſtament cite or mention them: neither Philo nor Joſephus ſpeak of them.

The Chriſtian church was for ſome ages an utter ſtranger to theſe books. Origen, Athanaſius, Hilary, Cyril of Jeruſalem, and all the orthodox writers, who have given catalogues of the canonical books of Scripture, unanimouſly concur in rejecting theſe out of the canon. And for the New Teſtament, they are divided in their opinions, whether the epiſtle to the Hebrews, the epiſtle of St. James, and the ſecond epiſtle of St. Peter, the ſecond and third epiſtles of St. John, the epiſtle of St. Jude, and the Revelations, are to be acknowledged as canonical or not.

The ſeveral epiſtles abovementioned, and the book of Revelations, are allowed by all the reformed churches to be parts of the canon of the New Teſtament.

The apocryphal books, however, according to the ſixth article of the church of England, are to be read for example of life and inſtruction of manners; but it doth not apply them to eſtabliſh any doctrine.

APOCYNUM, or DOGSBANE, a genus of the digynia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 30th order Contortæ. The eſſential characters; are the corolla is bell ſhaped, and the filaments are five, alternate with the ſtamina.

There are 11 ſpecies, of which the following are the moſt remarkable.

1. The venetum, with an upright herbaceous ſtalk, grows on a ſmall iſland in the ſea near Venice.

There are two varieties of this; one with a purple, and the other with the white flower. The roots creep very much, and by them only it is propagated; for it ſeldom produces any ſeeds.

2. The ſpecioſſimum, with large flowers, is a native of Jamaica in the Savannahs, whence it has the name of Savannah flower, by which it is generally known in that iſland.

3. Cordatum with a climbing ſtalk.

4. The villoſum, with hairy flowers and a climbing ſtalk. Theſe were diſcovered at La Vera Cruz in New Spain, by Dr. William Houſton, who ſent their ſeeds to England. They are both climbers and mount to the tops of the talleſt trees.

All the ſpecies of this plant abound with a milky juice, which flows out from any part of their ſtalks and leaves when they are broken: this is generally ſuppoſed to be hurtful if taken inwardly but doth not bliſter the ſkin when applied to it as the juice of ſpurge and other acrid plants.

APODECTÆ, in antiquity, was a denomination given to ten general receivers appointed by the Athenians to receive the public revenues, taxes, debts, and the like; who alſo had a power to decide controverſies ariſing in relation to money and taxes, all but thoſe of the moſt difficult nature and higheſt concern, which were reſerved to the courts of judicature.

APODECTÆI, in the Athenian government, were officers appointed to ſee that the meaſures of corn were juſt.

APODES, in a general ſenſe, denotes things without feet.

Apodes, in the Linnæan ſyſtem, is the name of the firſt order of fiſhes, or thoſe which have no belly-fins.

APODICTICAL, among philoſophers, is a term importing a demonſtrative proof, or ſyſtematical method of teaching.

APODOSIS, in rhetoric, makes the third part of a complete exordium, being properly the application, or reſtriction of the protaſis. It is the ſame with what is otherwiſe called axioſis; and ſtands oppoſed to protaſis: e. g. protaſis, all branches of hiſtory are neceſſary for a ſtudent; cateſceue, ſo that, without theſe, he can never make any conſiderable figure; apodoſis, but literary hiſtory is of a more eſpecial uſe, which recommends it, &c. &c.

APODYTERIUM, in the ancient baths, implied the apartments were perſons dreſſed and undreſſed themſelves

APOGEE, in aſtronomy, denotes that point in the orbit of a planet, which is at the greateſt diſtance from the earth.

The apogee of the ſun is that part of the earth's orbit which is at the greateſt diſtance from the ſun; and conſequently the ſun's apogee, and the earth's aphelion, are one and the ſame point.

APOGIATURA, in muſic, is a ſmall note inſerted by the practical muſician between two others.

The ſuperior apogiatura is ſuppoſed to affect love, affection, pleaſure, &c. It ſhould be made pretty long, giving it more than half the length of the time of the note it belongs to, and obſerving to ſwell the ſound by degrees.

The inferior apogiatura, has the ſame qualities with the ſuperior, only that is more confined, as it can be made only when the melody raiſes the interval of a ſecond or third, obſerving always to make a beat on the following note.

APOLIDES, in antiquity, denoted perſons who were condemned for life to the public works, or exiled into ſome iſland, and thus diveſted of the privileges of Roman citizens.

APOLISTÆ, in law, ſignifies the policy of diſarming the lower claſs of people in times of tumult, to avoid danger to the health of the ſtate.

APOLLINARIAN Games, in Roman antiquity, were thoſe inſtituted in the year of Rome 542. The occaſion of them was a kind of oracle delivered by the prophet Marcus after the fatal battle at Cannæ, declaring, that to expel the enemy, and cure the people of an infectious diſeaſe which then prevailed ſacred games were to be annually performed in honour of Apollo; the prætor to have the direction of them, and the decemviri to offer ſacrifices after the Grecian rite. The ſenate ordered that this oracle ſhould be obſerved the rather, becauſe another of the ſame Marcus, in which he had foretold the overthrow at Cannæ, had come true; for this reaſon they gave the prætor 12,000 aſes out of the public caſh to defray the ſolemnity. It was annually obſerved on the 5th of July.

APOLLO, in mythology, was a Pagan deity worſhipped by the Greeks and Romans.

Apollo had a variety of other names, either derived from his principal attributes, or the chief places where he was worſhipped.

He was called the Healer from his enlivening warmth and cheering influence.

Pæan, from the peſtilential heats: to ſignify the former, the ancients placed the graces in his right hand; and for the latter, a bow and arrows in his left.

Nomius, or the ſhepherd, from fertilizing the earth, and thence ſuſtaining the animal creation.

Delius, from his rendering all things manifeſt.

Pythius, from his victory over Python.

Lycias, Phœbus, and Phaneta, from his purity and ſplendor.

As Apollo is almoſt always confounded by the Greeks with the ſun, it is no wonder that he ſhould be dignified with ſo many attributes.

The power of healing diſeaſes being chiefly given by the ancients to medicinal plants and vegetable productions, it was natural to exalt into a divinity the viſible cauſe of their growth. Hence he was alſo ſtyled the god of Phyſic. Whether Apollo was ever a real perſonage, or not many have doubted. And Voſſius has taken great pains to prove this god to be only a metaphorical being, and that there never was any other Apollo than the ſun.

APOLLONIA, in antiquity, implies feaſts ſacred to Apollo, celebrated annually by the Egilations.

APOLLYON, in Scripture, is a Greek word which ſignifies the deſtroyer, and anſwers to the Hebrew *abaddon*.

St. John in the Revelations (ix. 11.) ſays, that an angel having opened the bottomleſs pit, a thick ſmoke iſſued out of it; and with this ſmoke locuſts, like horſes, prepared for battle, and commanded by the angel of the bottomleſs pit, called in Hebrew *abaddon*, but in the Greek *apollyon*.

APOLOGETIC, Apologetical, in rhetoric, implies ſomething ſaid or written, by way of excuſe or apology, for any action or perſon.

APOLOGUE, *Apologus*, in literature, ſignifies an ingenious method of conveying inſtruction by means of a feigned relation, called a moral fable.

The only difference between a parable and an apologue is, that the former, being drawn from what paſſes among mankind, requires probability in the narration; whereas the apologue, being taken from the ſuppoſed actions of brutes, or even of things inanimate, is not tied down to the ſtrict rules of probability.

Æſop's fables are a model of this kind of writing.

APOLOGY, is a Greek term, literally importing an excuſe or defence of ſome perſon or action.

APOLYSSIS, in a general ſenſe, implies a releaſe from any thing that confines or controuls a perſon: hence the word may be applied to almoſt all the common offices of life, including every art and ſcience,

APOMELI, among ancient phyſicians, denotes a decoction of honey and vinegar, much uſed as a detergent, promoter of ſtool, urine, &c.

APOMYOS Deus, in the Heathen mythology, was a name under which Jupiter was worſhipped at Elis, and Hercules as well as Jupiter at the Olympic games. The uſual ſacrifice was a bull.

APONEUROSIS, among phyſicians and anatomiſts, denotes the expanſion of a nerve or tendon in the manner of a membrane. It alſo implies the cutting off a nerve; and, finally, for the tendon it ſelf.

APONIA, in medical language, implies a freedom from pain, whether in the ſtate of the diſeaſe, or the mode of adminiſtring remedies or medicines.

APONOGETON, or Zannichellia, a genus of the digynia order, belonging to the heptandria claſs of plants, which has no Engliſh name. The calyx is an oblong omentum; there is no corolla; and the capſulæ are three ſeeded. There are two ſpecies, natives of the Indies.

APOPEMPTIC, in ancient poetry, was a hymn addreſſed to a ſtranger on his departure from a place to his own country.

APOPHASIS, denotes a figure in rhetoric, by which the orator, ſpeaking ironically, ſeems to wave what he would plainly inſinuate; as, "Neither will I mention thoſe things, which, if I ſhould, you notwithſtanding could neither confute nor ſpeak againſt them."

APOPHLEGMATIZANTS, in pharmacy, are medicines proper to clear the head from ſuperfluous phlegm.

APOPHTHEGM, in oratory, implies a ſhort, ſententious and inſtructive remark, pronounced by a perſon of diſtinguiſhed character.

APOPHYGE, in architecture, is a concave part or ring of a column, lying above or below the flat member.

APOPHYSIS, in anatomy, implies a protuberant ſtate of a bone, in jutting out beyond its proper limits.

APOPLECTIC, among phyſicians, denotes any thing that relates to an apoplexy.

APOPLEXY, in medical language, implies a diſtemper in which the patient is ſuddenly deprived of all his ſenſes, and of voluntary motion.

APORIA, is a figure in rhetoric, by which the ſpeaker ſhows, that he doubts where to begin.

Thus Cicero ſays, "Whether he took them from his fellows more impudently, gave them to a harlot, more laſciviouſly, removed them from the Roman people more wickedly, or altered them more preſumptuouſly, I cannot well declare."

APORON, or Aporime, denotes a problem difficult to reſolve, and which has never been reſolved, though it be not, in itſelf, impoſſible.

Such we conceive the quadrature of the circle; the duplicature of the cube; the triſection of an angle, &c.

APORRHOEA, or Aporrhoes, in phyſics and philoſophy, imply noxious effluvia flying off from morbid bodies.

APOSIOPESIS, in rhetoric, alſo called reticency, and ſuppreſſion; a figure, by which a perſon really ſpeaks of a thing, at a time when he makes a ſhew as if he would ſay nothing of it.

It is commonly uſed to denote the ellipſis.

This figure is of uſe to keep up the grandeur and ſublimity of a diſcourſe.

APOSITION, in the materia medica, imports a loathing of aliment.

APOSPHACELLISIS, in ſurgery, denotes a mortification by means of keeping the bandage too tight, on a wounded member of the body.

APOSPHRAGISMA, in antiquity, was the figure or impreſſion of a ſeal.

APOSTACY, or APOSTASY, in theology, imports the abandoning the true religion. The primitive Chriſtian church diſtinguiſhed ſeveral kinds of Apoſtacy. The firſt, of thoſe who went over entirely from Chriſtianity to Judaiſm; the ſecond, of thoſe who mingled Judaiſm and Chriſtianity together; and the third, of thoſe who complied ſo far with the Jews as to communicate with them in many of their unlawful practices, without making a formal profeſſion of their religion. But the fourth ſort was of thoſe who, after having been ſometimes Chriſtians, voluntarily relapſed into Paganiſm.

APOSTASIS, in medicine, the ſame with abſceſs.

APOSTATE, in eccleſiaſtical hiſtory, denotes one who deſerts his religion.

Among the Romaniſts, it ſignifies a man who, without a legal diſpenſation, forſakes a religious order of which he had made profeſſion. Hence,

APOSTATA CAPIENDO, in the Engliſh law, a writ that formerly lay againſt a perſon who, having entered into ſome order of religion, broke out again, and wandered up and down the country.

A POSTERIORI, in grammar, is the ſame with demonſtration.

APOSTIL, in matters of literature, the ſame with a marginal note.

APOSTLE, in Scripture language, implies a meſſenger ſent upon a ſpecial errand, Rom. xvi. 7. 2 Cor. viii. 23.

It is applied firſt to Chriſt Jeſus, who was ſent from Heaven to aſſume our nature, and work out our ſalvation, with authority to execute his prophetical and all his other offices, and to ſend forth his Apoſtles to publiſh the goſpel, Heb. iii. 1.

Secondly, to a miniſter immediately ſent from Chriſt to preach the goſpel, Matth. x. ii. Gal. i. 1.

APOSTLE properly ſignifies a meſſenger or perſon ſent by another upon ſome buſineſs; and hence, by way of eminence, denotes one of the diſciples commiſſioned by Jeſus Chriſt to preach the goſpel.

Our bleſſed Lord ſelected twelve out of the number of his diſciples to be inveſted with the apoſtleſhip. Their names were Simon Peter, Andrew, James the greater, John, Philip, Bartholomew, Thomas, Matthew, James the leſs, Jude ſirnamed Lebbeus or Thaddeus, Simon the Canaanite, and Judas Iſcariot. Of theſe Simon, Andrew, James the greater, and John, were fiſhermen; and Matthew a publican, or receiver of the public revenues: of what profeſſion the reſt were, we are not told in Scripture; though it is probable they were fiſhermen.

After the apoſtles had exerciſed their miniſtry for twelve years in Paleſtine, they reſolved to diſperſe themſelves in different parts of the world, and agreed to determine by lot what parts each ſhould take. According to this diviſion, St. Peter went into Pontus, Galatia, and thoſe other provinces of the Leſſer Aſia. St. Andrew had the vaſt northern countries of Scythia and Sogdiana allotted to his portion. St. John's was partly the ſame with Peter's, namely the Leſſer Aſia. St. Phillip had the Upper Aſia aſſigned to him, with ſome parts of Scythia and Colchis. Arabia Felix fell to St. Partholomew's ſhare. St. Matthew preached in Chaldæa, Perſia, and Parthia. St. Thomas preached likewiſe in Parthia; as alſo to the Hercanians, Bactrians, and Indians. St. James the leſs continued in Jeruſalem, of which church he was biſhop. St Simon had for his portion Egypt, Cyrene, Libya, and Mauritania; St. Jude, Syria and Meſopotamia; and St. Matthias, who was choſen in the room of the traitor Judas, Cappadocia and Colchis. Thus, by the diſperſion of the apoſtles, chriſtianity was very early planted in a great many parts of the world. We have but very ſhort and imperfect accounts of their travels and actions.

St. Paul is frequently called the apoſtle by way of eminence; and the apoſtle of the Gentiles, becauſe his miniſtry was chiefly made uſe of for the converſion of the Gentile world, as that of St. Peter was for the Jews, who is therefore ſtiled the apoſtle of the circumciſion.

The ſeveral apoſtles are uſually repreſented with their reſpective badges or attributes: St. Peter with the keys; St. Paul with a ſword; St. Andrew with a croſs or ſaltier; St. James minor with a fuller's pole; St. John with a cup, and winged ſerpent flying from it; St. Bartholomew with a knife; St. Philip with a long ſtaff, whoſe upper end is formed into a croſs; St. Thomas with a lance; St. Matthew with a hatchet; St. Matthias with a battle-ax; St. James major with a pilgrim's ſtaff and a gourd-bottle; St. Simon with a ſaw; and St. Jude with a club.

The appellation is given in like manner to thoſe perſons who firſt planted the Chriſtian faith in any place. Thus Dionyſius of Corinth is called the Apoſtle of France; Xavier the Apoſtle of the Indies, &c. In the Eaſt Indies the Jeſuit miſſionaries are alſo called Apoſtles.

APOSTLE is alſo uſed among the Jews for a kind of officer anciently ſent into provinces in their juriſdiction, as a commiſſary, to ſee that the laws were duly obſerved, and to receive the monies collected for the reparation of the temple, and the tribute payable to the Romans. Theſe Apoſtles were a degree below the officers of the ſynagogues called Patriarchs, and received their commiſſions from them. Some authors obſerve, that St. Paul had borne this office; and that it is this he alludes to in the beginning of the epiſtle to the Galatians: as if he had ſaid, Paul, no longer an apoſtle of the ſynagogue, nor ſent thereby to maintain the law of Moſes, but now an apoſtle and envoy of Jeſus Chriſt, &c.

APOSTLES *Creed*, in the Chriſtian religion, implies a formula, or ſummary of faith, drawn up by the apoſtles themſelves; who, during their ſtay at Jeruſalem, ſoon after our Lord's aſcenſion, agreed upon this creed, as a rule of faith, and as a word of diſtinction by which they were to know friends from foes.

APOSTOLARE, APOSTOLICARE, *Apoſtolizing*, in church hiſtory, denotes the being preferred to the dignity of pope; modernly termed the apoſtolic chair.

APOSTOLATE, in a general ſenſe, implies a miſſion.

In this ſenſe, Olearius has a diſcourſe concerning the apoſtolate of Chriſt.

APOSTOLATE more properly denotes the office of an apoſtle, or that of a biſhop.

In this ſenſe we meet with ſeveral letters, petitions, requeſts, &c. directed to biſhops under the title of your Apoſtolate, or Apoſtolatus Veſter.

But as the title Apoſtolicus had been appropriated to the Pope, ſo that of Apoſtolate became at length reſtrained to the ſole dignity of the popedom.

APOSTOLI, in law, denote thoſe letters miſſive which are demanded in caſes of appeal.

APOSTOLIC, APOSTOLICAL, ſomething that relates to the apoſtles, or deſcends from them.

APOSTOLIC, in the primitive church, was an appellation given to all ſuch churches as were founded by the apoſtles; and even to the biſhops of thoſe churches, as being the reputed ſucceſſors of the apoſtles. Theſe were confined to four, viz. Rome, Alexandria, Antioch, and Jeruſalem.

In proceſs of time, the biſhop of Rome growing in power above the reſt, and the three patriarchates of Alexandria, Antioch, and Jeruſalem, falling into the hands of the Saracens, the title apoſtolical was reſtrained to the pope and his church alone. Though ſome of the popes, and St. Gregory the Great, not contented to hold the title by this tenure, began, at length, to inſiſt, that it belonged to them by another and peculiar right, as being the ſucceſſors of St. Peter. The country of Rheims in 1049 declared that the pope was the ſole apoſtolical primate of the univerſal church. And hence a great number of apoſtolicals, apoſtolical ſee, apoſtolical nuncio, apoſtolical notary, apoſtolical brief, apoſtolical hamber, apoſtolical vicar, &c.

APOSTOLICAL *Fathers* is an appellation uſually given to the writers of the firſt century, who employed their pens in the cauſe of Chriſtianity.

APOSTOLIANS, in church hiſtory, were a ſect of the Mennonites, which firſt ſprung up in the year 1664, and derived its name from Apoſtool, one of the Mennonite miniſters at Amſterdam.

APOSTOLICI, or APOSTOLICS, in eccleſiaſtical hiſtory, was a name aſſumed by three different ſects, on account of their pretending to imitate the manner and practice of the apoſtles.

The firſt apoſtolici, apotactitæ, or apotactici, roſe out of the Encratitæ, and Cathari, in the third century. They made profeſſion of abſtaining from marriage, and the uſe of wine, fleſh, money, &c.

Sagarelli was the founder of the ſecond ſect; he obliged his followers to go from place to place as the apoſtles did, cloathed in white, with long beards, diſhevelled hair, and bare heads, accompanied with women, whom they called their ſpiritual ſiſters. They likewiſe renounced all kinds of property and poſſeſſions, inveighed againſt the growing corruption of the church of Rome, predicted its overthrow, and the eſtabliſhment of a new church on its ruin. Sagarelli was burnt alive at Parma in the year 1300, and was afterwards ſucceeded by Dulcinus, who added to the character of an apoſtle thoſe of a prophet and a general, and carried on a bloody and dreadful war for the ſpace of two years againſt Raynerius, biſhop of Vercelli; he was at length defeated, and put to death in a barbarous manner in the year 1037.

This ſect ſubſiſted till the beginning of the fifteenth century, when it was totally extirpated under the pontificate of Boniface XI.

The other branch of apoſtolici were of the twelfth century; they condemned marriage, preferring celibacy, and calling themſelves the chaſte brethren and ſiſters; though each was allowed a ſpiritual ſiſter, with whom he lived in a domeſtic relation, and on this account they have been charged with concubinage: they held it unlawful to take an oath; they ſet aſide the uſe of baptiſm; and in many things imitated the Manichees.

APOSTOLICUM is a peculiar name given to a hymn, on the articles of the Chriſtian faith, anciently uſed in churches.

APOSTOLORUM *Unguentum*, or Apoſtles ointment, in pharmacy, implies a compound of 12 mixtures, of a detergent or cleanſing nature.

APOSTROPHE, in rhetoric, is a figure by which a perſon who is either abſent or dead is addreſſed as if he was preſent.

This figure is, in boldneſs, a degree lower than the addreſs to perſonified objects; as it requires a leſs effort of imagination to ſuppoſe perſons preſent who are dead or abſent, than to animate inſenſible beings and direct our diſcourſe to them. The poems of Oſſian abound with the moſt beautiful inſtances of this figure. "Weep on the rocks of roaring winds, O Maid of Iniſtore! Bend thy fair head over the waves, thou fairer than the ghoſt of the hills when it moves in a ſun-beam at noon over the ſilence of Morven! He is fallen! Thy youth is low; pale beneath the ſword of Cuchullin!"

Apostrophe, in grammar, ſignifies the contraction of a word by the uſe of a comma: as call'd for called, tho' for though.

APOTACTITÆ, or **Apotactici**, in church hiſtory, were an ancient ſect, who affecting to follow the evangelical counſels of poverty, and the examples of the apoſtles and primitive Chriſtians, renounced all their effects and poſſeſſions.

APOTEICHISMUS, in the ancient military art, was a kind of line of circumvallation drawn round a place in order to beſiege it; which was alſo called periteichiſmus.

This anſwered to what are called lines of contravallation and circumvallation among the moderns.

APOTELESMA, **Apotelesmatica**, **Apotelesmata**, or **Apotelism**, in aſtrological calculation, ſeverally imply the act of foretelling future events, by conſulting the planets and aſpects. Hence, the caſting of nativities is called the ſcience of Apoteliſm; and the profeſſors of this deluſive art, Apoteleſmatici.

APOTHECARY, ſignifies one who practiſes the art of pharmacy.

In London, the apothecaries are one of the city companies; having been incorporated by a charter from king James I. procured at the ſolicitation of Dr. Mayerne and Dr. Aitkins; till that time they only made a part of the grocers company: plums, ſugar, ſpice, Venice treacle, mithridate, &c. were ſold in the ſame ſhop and by the ſame perſon.

The reaſon of ſeparating them was, that the medicines might be better prepared. By an act made in the ninth year of George I. they are exempted from ſerving upon juries, or in ward and pariſh offices, and are held in perpetuity with reſpect to their chartered rights.

They are obliged to make up their medicines according to the formulas preſcribed in the college diſpenſatory; and are liable to have their ſhops viſited by the cenſors of the college, who are empowered to deſtroy ſuch medicines as they think not good.

They have a hall in Black Friars, where there are two fine laboratories, out of which all the ſurgeons cheſts are ſupplied with medicines for the royal Britiſh navy.

To his majeſty belong two apothecaries: the ſalary of the firſt, is 320l. and that of the ſecond, 275l. beſides, to the houſehold belong two likewiſe.

Apothecary, *Apothecarius*, in hiſtory, denotes a ſhop-keeper, or ware-houſe keeper.

Apothecarius alſo denotes a ſtore-keeper or officer appointed to have the direction of a magazine, granary, &c. In which ſenſe apothecarii is ſometimes rendered by horearii and rationarii.

APOTHEOSIS, in antiquity was an heathen ceremony, by which their emperors and great men were placed among the gods.

After the apotheoſis, or deification and conſecration, temples, altars, and images, were erected to the new deity; ſacrifices, &c. were offered, and colleges of prieſts inſtituted.

The ceremony was as follows:

After the body of the deceaſed had been burnt with the uſual ſolemnities, an image of wax, exactly reſembling him, was placed on an ivory couch, where it lay for ſeven days, attended by the ſenate and ladies of the higheſt quality in mourning; and then the young ſenators and knights bore the bed of ſtate through the via ſacra to the old forum, and from thence to the campus martius, where it was depoſited upon an edifice built in form of a pyramid. The bed being thus placed amidſt a quantity of ſpices and other combuſtibles, and the knights having made a ſolemn proceſſion round the pile, the new emperor, with a torch in his hand, ſet fire to it, whilſt an eagle, let fly from the top of the building, and mounting in the air with a firebrand, was ſuppoſed to convey the ſoul of the deceaſed to heaven; and thenceforward he was ranked among the gods.

APOTHERAPIA, in phyſic, denotes a complete cure.

Apotherapia, in the gymnaſtic art, ſignifies the laſt part of all regular exerciſe, viz. unction with oil, before as well as after bathing. The deſign of this was partly to cleanſe the ſkin from any filth it might have contracted during the exerciſe, and partly to remove wearineſs.

APOTOME, in geometry, is the difference between two incommenſurable lines.

Euclid, lib. 10, def. 3. aſt. prop. 85, diſtinguiſhes Apotomes into 1ſt, 2d, 3d, 4th, 5th, and 6th, in the proportions following, viz.

The 1ſt is, when there are two numbers, ſuch, that the greater is a rational one, and the difference between their ſquares is a ſquare number.

The 2d is, when the leaſt number is rational, and the ſquare root of the difference of the ſquares of the two numbers has a ratio in numbers to the greateſt number.

The 3d is, when the two numbers are both irrational, and the ſquare root of the difference of their ſquares has a ratio in numbers to the greateſt number.

The 4th is, when the greateſt number is rational, and the ſquare root of the difference of the ſquares of the two numbers has not a ratio to that.

The 5th is, when the leaſt number is rational, and the ſquare root of the difference of the two numbers has not a ratio in numbers to the greateſt number.

The 6th is, when the numbers are irrational, and the ſquare root of the difference of their ſquares has not a ratio in numbers to the greateſt number.

The doctrine of Apotomes, as laid down by Euclid, in his 10th book, is a very curious ſubject, and extremely beneficial, as well as indiſpenſably neceſſary to be peruſed by all perſons who would wiſh to lay down geometrical elements; as from it may be deduced the poſſibility or impoſſibility of the quadratures of curvelineal figures, and perhaps lineal ſolutions of Diophantus's problems, and others of a ſimilar kind.

Apotome, in muſic, is the difference between a greater and leſſer ſemi-tone; expreſſed by the ratio as 128 is to 125.

The minor apotome is the interval of two ſounds, whoſe diſtinction is from 2025 to 2048, an interval ſtill leſs ſenſible to the ear than the preceding, which uſually bears the name of the Apotome major.

Thoſe graces require a peculiar delicacy in the ear, yet they are only natural harmony:

> For when nat'ral charms, unadorn'd by art,
> Emerges from its ſhell, —wond'ring where it lives:
> It flutters round; expands the heart;
> And feels the ſenſe that nature gives.

APOTROPÆA, in ancient poetry, were verſes compoſed for averting the wrath of incenſed deities; hence the deities invoked for averting any threatened misfortune were called Apotrepeans.

APOZEM, in medicine, the ſame with decoction.

APPARATUS, in arts and manufactures, denote a complete ſet of inſtruments, or utenſils, belonging to any artiſt or machine.

Apparatus, in ſurgery, implies the operation of cutting for the ſtone. For which there are three ſorts of apparatus, viz. the ſmall, great, and high.

Apparatus is alſo uſed as a title of ſeveral books compoſed in form of catalogues, bibliothecas, dictionaries, &c. for the eaſe and conveniency of ſtudy.

APPAREILLE, in fortification, ſignify the ſlope that leads to the platform of the baſtion.

APPAREILLES, imply eaſy aſcents to the works of a fortification.

APPARENT, in a general ſenſe, ſignifies that which is viſible to the eyes, or obvious to the underſtanding.

Apparent, among mathematicians and aſtronomers, denotes things as they appear to us, in contradiſtinction from real or true; thus we ſay, the apparent diameter, diſtance, magnitude, place, figure, &c. of bodies.

Apparent Heir, in law, no inheritance can veſt, nor can any perſon be the actual complete heir of another, till the anceſtor is previouſly dead. Before that time the perſon who is next in the line of ſucceſſion is called an heir apparent, or heir preſumptive.

Heirs apparent are ſuch, whoſe right of inheritance is indefeaſible, provided they outlive the anceſtor; as the eldeſt ſon or his iſſue, who muſt by the courſe of the common law be heirs to the real property, lands or houſes, of the father whenever he happens to die.

Heirs preſumptive are ſuch, who, if the anceſtor ſhould die immediately, would in the preſent circumſtances of things be his heirs: but whoſe right of inheritance may be defeated by the contingency of ſome nearer heir being born, as a brother or nephew, whoſe preſumptive ſucceſſion may be deſtroyed by the birth of a ſon, or daughter, whoſe preſent hopes may be hereafter cut off by the birth of a ſon. Nay, even if the eſtate hath deſcended, by the death of the owner, to a brother, a nephew, or daughter; in the former caſes, the eſtate ſhall be diveſted and taken away by the birth of a poſthumous child; and, in the latter, it ſhall alſo be totally diveſted by the birth of a poſthumous ſon.

APPARITION, in a general ſenſe, denotes ſimply the ſhadow or appearance of a thing.

In a more limited ſenſe, it implies a ſpectre or ghoſt.

Several inſtances of apparitions occur in the bible: and that of Samuel raiſed by the witch of Endor, has occaſioned many diſputes.

As partial darkneſs, or obſcurity, is the moſt powerful means by which the ſight is deceived; night is therefore the proper ſeaſon for apparitions. Indeed the ſtate of the mind, at that time, prepares it for the admiſſion of thoſe deluſions of the imagination.

The fear and caution which muſt be obſerved in the night; the opportunity it affords for cutting off many pleaſing trains of ideas, which objects in the light never fail to introduce, are all circumſtances of terror: and perhaps, ſo much of our happineſs depends upon our ſenſes, that the deprivation of any one may be attended with proportionable horror and uncaſineſs.

Mr. Hobbes has ingeniouſly accounted for the ſpectre which is ſaid to have appeared to Brutus. "We read," ſays he, "of M. Brutus, that at Philippi, the night before he gave battle to Auguſtus Cæſar, he ſaw a fearful apparition, which is commonly related by hiſtorians as a viſion; but, conſidering the circumſtances, one may eaſily judge it to have been but a ſhort dream. For ſitting in his tent, penſive and troubled with the horror of his raſh act, it was not hard for him, ſlumbering in the cold, to dream of that which moſt affrighted him; which fear, as by degrees it made him wake, ſo it muſt needs make the apparition by degrees to vaniſh: and having no aſſurance that he ſlept, he could have no cauſe to think it a dream, or any thing but a viſion."

APPARATOR, in the Roman law, was a general term to comprehend all attendants of judges and magiſtrates appointed to receive and execute their orders.

Apparitor, in Engliſh eccleſiaſtical law, is a meſſenger that ſerves the proceſs of a ſpiritual court.

Alſo a beadle in an univerſity who carries the mace, is called by the ſame name.

APPARURA, in the old huſbandry, as well as in law deſcription and hiſtorical records, denoted the tackle, or furniture of any ſort of inſtrument uſed in cultivating the ground, and in a particular ſenſe indicated the plough uſed in fallowing the land previous to ſeed ſowing.

APPAUMEE, in heraldry, denotes one hand extended, with the full palm appearing, and the thumb and fingers at full length.

APPEAL, in law, is the removal of a cauſe from an inferior to a ſuperior court, when a perſon thinks himſelf aggrieved by the ſentence of the court below.

Appeals lie from all the ordinary courts of juſtice to the houſe of lords.

In eccleſiaſtical caſes, if an appeal is brought before a biſhop, it may be removed to the archbiſhop; but, if before an archdeacon, to the court of arches, and thence to the archbiſhop; and afterwards to the king in chancery.

Appeal, in criminal crown law, denotes an accuſation by a private ſubject againſt another, for ſome heinous crime; demanding puniſhment on account of the particular injury ſuffered, rather than for the offence againſt the public. For the particular caſes in which an appeal will lie, ſee Syſtem of Common Law, under the head Crown Law.

APPEARANCE, in a general ſenſe, implies the exterior ſurface of a thing, or that which immediately ſtrikes the ſenſes.

Appearance, in law, ſignifies a defendant's filing a common or ſpecial bail, on any proceſs iſſued out of a court of judicature.

APPEASING, in a general ſenſe, implies all ways, means, and methods of reducing the maladies of body and mind: hence appeaſing remedies, appeaſing orations, &c. &c.

APPELLANT, in a general ſenſe, one who appeals.

Appellants, in church hiſtory, ſignifies an appellation given to ſuch of the catholic clergy as appeal from the conſtitution unigenitus to a general council.

APPELLATION, the name by which any thing is known or diſtinguiſhed when ſpoken of. Nothing can be more foreign to the original meaning of many words and proper names, in the Engliſh language, than their preſent appellations. Who, for example, when the crier of a court calls out, "O yes, O yes," would ſuppoſe that it was a proclamation commanding the talkers to become hearers, being the French word *Oyez*, "liſten," retained in our courts ever ſince the pleadings were held in law French? Or would any perſon ſuppoſe that the head-land on the French coaſt, near Calais, called by our ſeamen Blackneſs, could be ſo titled from its French name of *Blanc*.

King Henry the Eighth having taken the town of Bullogne in France, the gates of which he brought to Hardes in Kent, where they are ſtill remaining, the flatterers of that reign highly magnified this action, which, Porto Bello like, became a popular ſubject for ſigns; and the port or harbour of Bullogne, called *Bullogne mouth*, was accordingly ſet up at a noted inn in Holborn; the name of the inn long out-living the ſign and fame of the conqueſt, an ignorant painter employed by a no leſs ignorant landlord, to paint a new one, repreſented it by a bull and a large gaping human mouth (anſwering to the vulgar pronunciation of *Bull and Mouth*). The ſame piece of hiſtory gave being to the *Bull and Gate*, originally meant for Bullogne gate, and repreſented by an embattled gate or entrance into a fortified town.

The *barber's pole* has been the ſubject of many conjectures; ſome conceiving it to have originated from the word *poll*, or head, with ſeveral other conceits as far-fetched, and as unmeaning: but the true intention of that party-coloured ſtaff was to ſhow that the maſter of the ſhop practiſed ſurgery, and could open a vein as well as mow a beard; ſuch a ſtaff being to this day, by every village-practitioner, put into the hand of a patient undergoing the operation of phlebotomy. The white band which encompaſſes the ſtaff, was was meant to repreſent the fillet, thus elegantly twined about it.

Nor were the chequers (at this time a common ſign of a public-houſe) leſs expreſſive, bein[illegible] repreſentation of a kind of draught-board called tables, and [illegible]ed that tha game might be played there. From their colour which was red, and the ſimiliarity to a lattice, it was corruptly called the *red lettuce*, which word is frequently uſed by ancient writers to ſignify an alſehouſe.

The Spectator has explained the ſign of the *bell ſavage inn* plauſibly enough, in ſuppoſing it to have been originally the figure of a beautiful female found in the woods, called in French *la belle ſauvage*. But another reaſon has ſince been aſſigned for that appellation, namely, that the inn was once the property of Lady Arabella Savage, and familiarly called Bell Savage's inn, probably repreſented, as at preſent, by a bell and a ſavage or wild man, which was a rebus for her name; rebuſſes being much in faſhion in the 16th century, of which the bolt and tun is an inſtance.

The *three blue balls* prefixed to the doors and windows of pawnbrokers ſhops, by the vulgar humorouſly enough ſaid to indicate that it is two to one that the things pledged are ever redeemed, was in reality the arms of a ſet of merchants from Lombardy, who were the firſt that publicly lent money on pledges. They dwelt together in a ſtreet, from them named Lombard ſtreet, in London, and alſo gave their name to another at Paris. The appellation of Lombard was formerly all over Europe conſidered as ſynonymous to that of uſurer.

At the inſtitution of yeomen of the guards, they uſed to wait at table on all great ſolemnities, and were ranged near the buffets; this procured them the name of buffetiers, not very unlike in ſound to the jocular appellation of beef-eaters, now given them; though probably it was rather the voluntary miſnomer of ſome wicked wit, than an accidental corruption ariſing from ignorance of the French language.

APPELLATIVE Names, in grammar, in contradiſtinction to proper names, are ſuch as ſtand for univerſal ideas, or a whole rank of beings, whether general or ſpecial; e. g. Fiſh, Bird, Man, City, River, are common or appellative names; and ſo are Trout, Eel, Lobſter; for they all agree to many individuals, and ſome to many ſpecies.

APPELLEE, among lawyers, is the perſon againſt whom an appeal is brought.

APPENDANT, in law, implies any thing that is inheritable, belonging to ſome more worthy inheritance; as an advowſon, common, or court, may be appendant to a manor land, office, &c. but land cannot be appendant to land, for both are corporeal inheritances; and one thing corporeal cannot be appendant to another.

APPENDICULA, in grammatical conſtruction, denotes a ſmall appendix, or abſtract heads, of a performance already read or written.

APPENDIX, in literature, is a ſupplement alphabetically added at the end of a work, to render it more complete.

APPERCEPTION, or **Adperception**, is a term uſed by Leibnitz and his followers for conſciouſneſs.

APPETITE, in a general ſenſe, indicates the deſire of enjoying ſome object, ſuppoſed to be conducive to our happineſs.

When this inclination is guided by reaſon, and proportioned to the intrinſic value of the object, it is called rational appetite; but on the other hand it is denominated ſenſitive appetite, when we have only a blind propenſity to a thing, without determinate ideas of the good qualities for which we deſire it.

Appetites are paſſions directed to general objects, in contradiſtinction to paſſions directed to particular objects, which retain their proper name. Thus we ſay, an appetite for fame, for glory, for conqueſt, for riches; but we ſay, the paſſion of love, of gratitude, of envy, &c.

Appetite may be alſo diſtinguiſhed from paſſion, ſince the latter has no exiſtence till a proper object be preſented; whereas the former exiſts firſt, and then is directed to an object.

Appetite, in medicine, is a painful ſenſation, accompanied with a deſire to eat or drink.

An exceſſive appetite is called by phyſicians bulimy, or fames canina; a defect or loſs of it, anorexy; and that after things improper for food, pica.

APPLAUSE, in a general ſenſe, implies, an approbation, ſignified by clapping the hands, as now practiſed in theatres. Applauſe, in antiquity, differed from Acclamation, as the latter was articulate, and performed with the voice, the former with the hands.

Applause, among the Romans, was an artificial muſical kind of noiſe, made by the audience to expreſs their ſatisfaction.

There were three ſpecies of applauſe, denominated from the different noiſes made in them; viz. Bombus, Imbrices, and Teſtæ; the firſt was a noiſe made either by the hands or mouth; the ſecond and third, by beating on a ſort of ſounding veſſels placed in the theatres for this purpoſe.

APPLE, the fruit of the pyrus malus.

Apple *of the Eye*, a name not unfrequently given to the pupil.

Apples *of Love*, the ſame as Lycopersicon.

Mad Apples, the ſame as Melongena.

Applicate, Applicata, or Ordinate, in geometry, denotes a right line drawn acroſs a curve, ſo as to be biſected by its diameter.

APPLICATION, in a general ſenſe, is the laying two things together, in order to diſcover their agreement or diſagreement.

Application, in geometry, implies diviſion, or applying one quantity to another, whoſe areas (but not figures) ſhall be the ſame; or, for transferring a given line into a circle, or other figure, ſo that its ends ſhall be in the periameter of the figure.

Application, in theology, ſignifies the act by which our Saviour tranſfers to us, what he has purchaſed by his holy life and death.

Accordingly, it is by this application of the merits of Chriſt, that we are to be juſtified, and intitled to grace and glory.

The ſacraments are the ordinary means by which it is effected.

APPOGIATURA, in muſic, implies the ſame as Apogiatura.

APPOINTEE, a foot-ſoldier in the French army, who, for his long ſervice and bravery, receives pay above private centinels.

Appointee, in heraldry, is the ſame as Aguiſée: thus we ſay, a croſs appointée, to ſignify that with two angles at the end cut off, ſo as to terminate in points.

APPOINTMENT, in a general ſenſe, imports the ſame as Assignation.

Appointment, in a particular ſenſe, denotes a penſion or ſalary given by princes to perſons of worth and parts, in order to retain them in their ſervice.

Appointments differ from wages; as the latter are fixed and ordinary, but the former are annual gratifications, granted by brevet for a time uncertain, and are paid out of the privy purſe.

APPORTIONMENT, or Apportionamentum, in law, implies the dividing of a rent into parts, in the ſame manner as the land from which it iſſues is divided.

However, conditions are always entire, and cannot be ſubjected to apportionment by any act of the party; neither can a contract be apportioned ſo as to ſubject a man to two actions.

APPOSAL *of Sheriffs*, in law, denotes a debit entry againſt them in the exchequer.

APPOSER, in common or eccleſiaſtical law, ſignifies an examiner. In the court of exchequer there is an officer called the Foreign Appoſer.

APPOSITION, in grammar, ſignifies the placing of two or more ſubſtantives together in the ſame caſe, without any copulative conjunction between them; as, *Ardebat*, *Alexim*, *delicias domini*.

APPRAISER, in trade, denotes a perſon who rates or values goods, &c.

They are generally employed in caſes of death, executions brought in upon goods, or of ſtock to be turned over from one perſon to another, or divided between copartners; and are called Sworn Appraiſers, from their taking an oath to do juſtice between party and party.

APPRAISING, the act of rating or valuing goods by an appraiſer.

APPREHENSION, in logic, denotes the ſimple attention of the mind to an object preſented to our imagination, without paſſing a judgment or making any inference.

Apprehension likewiſe indicates an inadequate idea; and thus it is applied to our knowledge of God, in contradiſtinction to comprehenſion.

Apprehension, in law, ſignifies the ſeizing a criminal, in order to bring him to juſtice.

APPRENTICE, in the legal acceptation of the word, implies one who is bound by covenant to ſerve a tradeſman or artificer a certain time, upon condition of the maſter's inſtructing him in his art or myſtery. See Syſtem of Law.

Anciently, benchers in the inns of court were called *apprentices of the law*, in Latin *apprenticii juris nobiliores*; as appears by Mr. Selden's note on Forteſcua: and ſo the learned Plowden ſtyles himſelf. Sir Henry Finch, in his *Nomotechnia*, writes himſelf, *apprentice dë lev:* Sir Edward Coke in his *Inſt.* ſays, *Apprenticii legis*, in pleading, are called *homines conſiliarii et in lege periti*; and in another place, *apprentices* and in other, counſellors at law.

Apprentices indentures and articles of clerkſhip, pay of duty ſix ſhillings. Pariſh indentures are excepted, and pay ſixpence only, by 5 W. 3. c. 21. For fees given with apprentices, clerks, or ſervants, bound or articled by indentures, from 1l. to 50l. maſters pay for every pound ſixpence; and for fees above 50 l. one ſhilling in the pound. 8 Ann, c. 9.

APPRENTICESHIP, the ſervitude of an apprentice, or the duration of his indenture. See Syſtem of Law.

APPROACH, or Approaching, in a general ſenſe, the acceding or coming together of two or more bodies or things.

Approaches, in fortification, the works thrown up by the beſiegers, in order to get nearer a fortreſs, without being expoſed to the enemy's cannon.

APPROACHING, in the manege, is a term uſed to expreſs ſuch devices as are contrived for the getting within ſhot of ſhy birds.

The beſt method of approaching is by means of three hoops tied together at proper diſtances according to the height of the man that is to uſe it, and having boughs of trees tied all round it, with cords to hang it over his ſhoulders; a man getting into this, conceals himſelf, and approaches by degrees towards his game in the form of a moving buſh. Geeſe, ducks, and teal, quit the waters in the evening, and paſs the night in the fields; but at the approach of morning they return to the water again, and even when on the water they will retire to great diſtances, on the approach even of a horſe or cow, ſo that the buſineſs of the ſtalking horſe is of little uſe; but this device of approaching by the moving buſh ſucceeds tolerably well with them.

Approaching, in gardening, is the inoculating or ingrafting the ſprig of one tree into another, without cutting it off the parent-tree.

APPROBATION, in morality, is a ſtate or diſpoſition of the mind, wherein we put a value upon, or become pleaſed with, ſome perſon or thing.

Approbation, in a moral ſenſe, is a principle of benevolence by which we are determined to approve of every kind affection either in ourſelves or others; and all publicly uſeful actions, which we imagine to flow from ſuch affection, without any view to our own private happineſs.

Approbation, in literature, implies the recommendation of books, by perſons qualified or authoriſed to judge of them. Hence, the learned bodies of public critics or reviewers who report the merits of every publication in England.

APPROPRIATION, in the canon law, implies a ſevering of a benefice eccleſiaſtical to the proper and perpetual uſe of ſome religious houſe.

APPROVEMENT, in ancient records of hiſtorical facts, imply the ſame as the modern word improvement.

In law, it denotes the incloſing part of a common by the lord of the manor.

If, however, there be not ſufficient common left to the tenant, he may have a writ of aſſize and recover triple damages: or he he may without enquiry break down the fence of the encloſure, as an action againſt the ſtatute.

APPROVER, in law, denotes a perſon who, confeſſing felony in himſelf, appealeth or impeach his accomplices. This proof was anciently either by battle, or by the country, at the choice of the appellee.

Approvers *of the King*, are thoſe who have the letting of the king's demeſnes in ſmall manors, &c. In the ſtatute of the 1ſt of Ed. 3. c. 8. ſheriffs are called the king's approvers.

Approver, or Appruare, is particularly uſed in ancient law, for a bailiff or land-ſteward, appointed to have the care of a manor, to improve it, for the benefit of his maſter.

APPROXIMATION, in arithmetic and algebra, indicates the coming nearer to a root, or quantity ſought, without expecting to find it exactly.

APPULSE, in aſtronomy, is the approach of any planet to a conjunction with the ſun, or a ſtar. It is a ſtep towards a tranſit, occultation, conjunction, eclipſe, &c.

APPURTENANCES, in law, denote the ſeveral rights, members, and privileges, appertaining to a thing already in poſſeſſion, whether corporeal as hamlets, or commonage; or incorporeal, as matters of liberty annexed to a meſſuage or tenement in occupation. Hence, a right of fiſhing in a particular river, ſtream or pond; or a ſeat in a church, booth on a green, &c. are ſaid to be appurtenances of a farm taken for a leaſe of lives or years.

APRICOT, in botany, the ſame as Prunus.

APRIL, in chronology, is the fourth month of the year, according to the common computation; but the ſecond, according to that of the aſtronomers. It contains 30 days. The word is derived from *aprilis*, of *aperio*, "I open;" becauſe the earth, in this month, begins to open her boſom for the production of vegetables.

A PRIORI, in rhetoric, implies a kind of demonſtration.

APRON, in naval architecture, is a piece of curved timber fixed behind the lower part of the ſtern, immediately above the foremoſt end of the keel.

Apron is alſo a name given to a platform or flooring of plank, raiſed at the entrance of a dock, againſt which the dock-gates are ſhut.

Apron, in gunnery, is a piece of lead which covers the touch-hole of a great gun.

APSINTHUM, or Absinthiatum, in medicine, denotes a ſtrengther of the ſtomach.

APSIS, or Absis, ſignifies the bowed or arched roof of a houſe, room, or oven, &c. as alſo the ring or compaſs of a wheel.

Apsis, in eccleſiaſtical writers, denotes an inner part in the ancient churches, in which the clergy ſat, and where the altar was placed.

Apsis, amounts to the ſame with what is otherwiſe called Choir, Concha, Camera, and Preſbyterium; and ſtands oppoſite to the nave or body of the church.

Apsis likewiſe denoted the biſhop's ſeat, in ancient churches.

Apsis alſo implies a reliquary, or caſe, in which the relics of ſaints were anciently kept.

Apsis, in aſtronomy, is a term uſed indifferently for either of the two points of a planet's orbit, where it is at the greateſt or leaſt diſtance from the ſun or earth; and hence the line connecting thoſe points is called the line of the apſides.

The apſis at the greateſt diſtance from the ſun is called the aphelion, and at the greateſt diſtance from the earth apogee; and that at the leaſt diſtance from the ſun is termed the perihelion, and at the leaſt diſtance from the earth the perigee.

APSERTIDES, the ſame as ABSORUS.

APTERA, in the Linnæan ſyſtem, denotes the ſeventh order of inſects, comprehending ſuch as have no wings, making together 14 genera, or families, and 297 ſpecies, or different kinds, in their common-wealth of nature.

APTHANE, a title anciently given to the higher degrees of nobility in Scotland.

APTITUDE, ſignifies the natural diſpoſition any thing hath to ſerve in its place. Thus, oil hath an aptitude to burn, and water to extinguiſh fire.

APTITUDE, or APTNESS, in philoſophy, implies the talents of the mind, for a promptitude or diſpoſition to learn things with eaſe and expedition.

In which ſenſe *aptneſs* amounts to the ſame with what the Greeks call *ευμαθια*, *bona indoles*, and we ſometimes *docility*.

APTOTE, among grammarians, is an undeclinable noun, or one which has no variation of caſes.

APUA, in ichthyology, denote ſynonymies of the vera, phalerica, and pilchard.

APUS, in ornithology, denotes a ſpecies of the ſwallow.

APUS, in entomology, denotes a ſpecies of the monaculus order of inſects.

APUS, *Avis Indica*, in aſtronomy, is a conſtellation of the ſouthern hemiſphere, placed near the pole, between the triangulum auſtrale and the chameleon, ſuppoſed to repreſent the bird of Paradiſe.

APYCNI SUONI, in muſic, are ſounds diſtant one or more octaves, and yet concord.

APYCNOS, in muſic, is ſaid to be of the diatonic genus, on account of its having ſpacious intervals, in compariſon of the chromatic and enharmonic.

APYRENOS, in natural hiſtory, denotes fruit of the nut kind, which have no kernel; hence, the popular name of blind, or barren nuts.

APYREXY, among phyſicians, denotes the intermiſſion of a fever.

APYROI, in ancient religious rites, were altars, on which ſacrifices were offered without fire, contradiſtinguiſhed from Empyroi, or thoſe on which fire was kindled to conſume the oblation.

APYROMETALLUM, in metallurgy, a technical term for gold or any pure metal, which reſiſts the force of fire.

APYRON, in chemiſtry, denotes any ſubſtance which is produced natural, which uſually requires fire in the proceſs of its production or manufactory.

APYROUS, in phyloſophy, is a word generally applied to denote that property of ſome bodies, by which they reſiſt the moſt violent fire without any ſenſible alteration.

Apyrous bodies are diſtinguiſhed from thoſe which are refractory.

Refractory ſubſtances are thoſe which cannot by violent heat be fuſed, whatever other alteration they may ſuſtain.

But a body, properly ſpeaking, apyrous, can neither be fuſed by heat, nor can undergo any other change.

AQUA, in experimental philoſophy, is a term uſed by phyſicians, chemiſts, &c. to denote medicines, or menſtruums, in a liquid form, diſtinguiſhed from each other by peculiar epithets, as Aqua Alexiteria, Aqua Aluminoſa, Aqua Mirabilis, &c.

AQUA *Extincta*, or *Extinguiſhed Water*, is aquafortis, into which ſome river-water has been poured, to qualify it, and render it leſs corroſive.

Its uſe is to get the ſilver from the aquafortis that ſerved to part gold from it.

AQUA *Fortis*, is a nitrous acid of a certain ſtrength, from its diſſolving power: and that which is concentrated and ſmoking, is called ſpirit of nitre.

The aquafortis uſed by dyers, braſs-founders, &c. is not only weaker than ſpirit of nitre, but contains a portion of vitriolic acid.

The nitrous acid, expelled by the vitriolic, will riſe in red fumes, and paſs into the receiver.

The vitriolic acid, uniting with the alkaline baſis of the nitre, forms vitriolated tartar; but, if more vitriolic acid than is requiſite to ſaturate the alkali, the ſurplus riſes with the nitrous acid. Aquafortis, therefore, is a mixture of theſe two acids.

AQUA *Marina*, ſignifies the beryl; it is ſo called on account of its ſea-green colour.

AQUA *Regia*, is a compound of nitrous and marine acid, in different proportions according to the purpoſe for which it is intended.

A pure aqua regia may be made by ſimply mixing the two acids.

Aqua regia is particularly uſed as a menſtruum for gold it diſſolves all other metals, except ſilver.

The gold diſſolved in aqua regia is, in fact, diſſolved in the dephlogiſticated marine acid only, which, being deprived of its phlogiſton by the nitrous acid, recovers it from the gold, and thus renders gold ſoluble; for metals are not ſoluble in acids until they loſe a part of their phlogiſton.

AQUA *Secunda*, is aquafortis diluted with pure water. It is employed in ſeveral arts, to clean the ſurface of metal, ſtones, and various other purpoſes.

AQUA *Vitæ*, or ſtrong ſpirit, is commonly underſtood brandy, ſpirit of wine, or any other liquid of ſtrength.

AQUÆDUCT, in hydraulics and architecture, implies a ſtructure formed for conveying water from one place to another, over grounds that are unequal. The word is compounded of the Latin ſubſtantive *aqua* water, and *ductus* a channel, by which that water may be conducted.

Architects diſtinguiſh two kinds of aquæducts; the viſible, and the ſubterranean. The viſible is conſtructed in valleys or marſhes, and protracted in longitude or latitude, as the ſituation requires. They are compoſed of adminicula for ſupporting the arches and confining the ſtream, and of arcades. The ſubterranean is formed, by piercing the mountains, and conducting them below the ſurface of the earth; built of ſtone, and covered above with vaults, or with flat ſtones, which may be termed flags; theſe flags ſhelter the waters from the heat of the ſun.

AQUAGE, in levelling, implies the race or courſe of a mill-ſtream, previous to its entrance into the damn for the head, where the ſluice riſes to let the water paſs to the water wheel. It alſo denotes any courſe where water has a deſcent, ſo as to run towards the ſea.

AQUALICULUS, in anatomy, is the pubes or region of the human body, where the privy members are placed at the termination of the trunk, or upper parts of the thighs.

AQUAMANILIS, in church hiſtory, denotes the laver uſed in the primitive days of Chriſtianity to waſh the hands in, on the entrance into the porch of a church, to ſignify a cleanſing from ſin; but this cuſtom, as a relick of Judaiſm, has been long ſince deſervedly laid aſide.

AQUARIANS, in eccleſiaſtical hiſtory, were Chriſtians in the primitive church who conſecrated water in the euchariſt inſtead of wine; under the pretence of abſtinence and temperance; holding it unlawful to eat fleſh or drink wine.

AQUARIUS, or the water-carrier, in aſtronomy, is the 11th ſign in the zodiac, reckoning from Aries; from which alſo the 11th part of the ecliptic takes its name. The ſun moves through Aquarius in the month of January; it is marked thus, ♒.

In mythology, the poets feign, that Aquarius was Ganymede, whom Jupiter carried to heaven, to ſerve as a cup-bearer, inſtead of Hebe, whence the name. But naturaliſts hold, that the ſign was ſo called, becauſe, when it appears in the horizon, the weather uſually proves rainy.

The ſtars in the conſtellation Aquarius, in Ptolemy's catalogue, are 45; in Tycho's 41; in Hevelius's 47; in Flamſtead's 108. The latter account ſeems to be neareſt the truth.

AQUATIA, AQUITICA, or AQUATICUM, in law, were formerly repreſented a tenant's right to the fiſhery or watering of a certain river, ſtream, pond, or lake. Hence, all ancient grants, by deed, had the aquatia mentioned as a neceſſary parcel of the habendum.

AQUARTIA, in botany, a genus of the tetrandria monogynia claſs; whoſe calyx is companulated; the corolla rotated, with linear diviſions; and the berry is four-ſeeded. There is but one ſpecies, the aculeata, a native of America.

AQUATIC, in natural hiſtory, is an appellation given to ſuch things as live or grow in the water.

AQUATINTA, in the fine arts, is a method of etching on copper, lately invented, by which a ſoft and beautiful effect is produced, reſembling a fine drawing in water colours or Indian ink.

Previous to the operation upon the plate, the followig powder muſt be prepared. Take of aſphaltum and fine tranſparent roſin, equal parts, ſuppoſe two ounces of each, and pound them ſeparately; through a muſlin ſieve, which may be formed with part of a chip-box of three or four inches in diameter, ſift upon a ſheet of paper a thin ſtratum of the aſphaltum, above which ſift a ſimilar layer of the roſin, and upon this another layer of aſphaltum, continuing theſe alternate layers till both of the powders are exhauſted: then paſs the mixture through the ſieve upon the paper once or twice, or till both appear to be ſufficiently incorporated; when the powder is ready for uſe. Some, inſtead of the above mixture, uſe gum ſandarach pounded. The main proceſs is then to be purſued as follows:

A copper-plate being poliſhed in the uſual way, lay the etching ground upon it, and etch the outlines of your deſign in the manner directed under the article ETCHING: the ground is then to be ſoftened with a little greaſe, and wiped off with a piece of rag; leaving, however, as much greaſe upon the plate as to dim the copper; then ſift the powder upon the ſurface of the plate; after which, ſtrike the other ſide of it pretty ſmartly againſt the edge of the table, in order to diſcharge it of the looſe powder; this done, with a hand-vice hold the back of the plate over a chaffing-diſh of charcoal fire, till it become ſo hot as to give pain upon being touched with the back of the hand; and the powder which adhered to the greaſe will now be fixed to the plate.

The plate being then ſuffered to cool, take turpentine varniſh mixed with ivory black; and with a hair-pencil dipt in it, cover all the lights or places where there is no work or ſhades. A rim or border of bees-wax is now to be raiſed round the plate: then having reduced the aquafortis to a proper ſtrength by vinegar or water, you pour it on, and let it ſtand five minutes for the firſt or lighteſt ſhade: after which, pour it off; and having waſhed the plate with water, ſet it on edge to dry: then with the varniſh ſtop up your light ſhades, pour on the equafortis for the ſecond tint, and let it ſtand five minutes more; proceeding in the ſame manner for every tint till you produce the darkeſt ſhades. If a bold open ground is wanted in any part, this requires an after-operation.

The ground muſt be laid as the other, by ſifting on the powder; this powder is to be much coarſer, and the plate muſt be much more heated, in order that the particles of the powder may ſpread, and form ſmall circles: even good clean roſin will do by itſelf.

In etching landſcapes, the ſky and diſtant objects are alſo performed by a ſecond operation, and the powder is ſifted upon the plate with a finer ſieve.

If the trees or any part of the fore-ground require to be higher finiſhed, the plate muſt be entirely cleanſed from greaſe with bread, and a ground laid in the common way of etching; when you may finiſh as highly and neatly as you pleaſe with the needle or point, by ſtippling with dots, and biting up thoſe parts, or by a r ling-wheel.

This art is kept as ſecret as poſſible by thoſe who practiſe it; and it is believed that no particular explanation or directions, before the preſent, except by one author, have been communicated to the public.

AQUEOUS, in a general ſenſe, implies a thing partaking of the nature of water.

AQUILA, in ornithology, a ſynonyme of the eagle.

Aquila, the eagle, in aſtronomy, is a conſtellation of the northern hemiſphere; uſually joined with Antinous. The ſtars in the conſtellation Aquila and Antinous, in Ptolemy's catalogue, are 15; in Ticho's, 19; in Heveius's, 42; in the Britannic catalogue 71.

Aquila, in chemiſtry, expreſſes ſynonymies of the ſeveral operations and ſubſtantives which are occaſionally joined to this epithet.

AQUILEGIA, columbine, a genus of the pentagynia order, belonging to the polyandria claſs of plants; and, in the natural method, ranking under the 26th order, Multiſiliquæ. It has no calyx; the petals are five, with a horn-like nectarium inſerted between each; and there are five ſeparate capſules. There are four ſpecies:

1. The vulgaris, or wild columbine, with blue flowers, grows wild in England.

2. The alpina, with long oval flowers, grows naturally in Yorkſhire.

3. The inverſa, or garden columbine; there are great varieties, both in colour, fulneſs of the flowers, and form. Theſe are commonly called roſe-columbines; the colours are cheſnut, blue, red, and white, and ſome are finely variegated with two colours.

4. The canadenſis, or Canada columbine, preſerved in the gardens of the curious, though not at all remarkable for its beauty.

Theſe plants are all propagated by ſowing the ſeeds, or parting the old roots; but the former method is chiefly practiſed, for the old roots are very apt to degenerate.

Columbine has been looked upon as aperient; and was formerly in great eſteem among the common people for throwing out the ſmall-pox and meaſles.

AQUILICIUM, or Aquiliciana, in Roman antiquity, were ſacrifices performed in times of exceſſive drought, to obtain rain of the gods.

AQUILIFEER, in the Roman armies, denoted the officer who carried the ſtandard on which the eagle was repreſented.

AQUILINE, denotes ſomething reſembling an eagle; thus, an aquiline noſe is one bent ſomewhat like an eagle's beak.

AQUILUS, among the ancients, was a dark or duſky colour, approaching to black.

AQUIMINARIUM, in antiquity, is a kind of luſtral veſſel, in which the Romans carried their holy water for expiation, and other religious offices.

AQUIQUI, a ſynonyme of the king monkey of Brazil, in South America,

ARA Thuribuli, or the Altar of Incence, in aſtronomy, a ſouthern conſtellation, not viſible in our hemiſphere, conſiſting of nine ſtars.

Ara, or Altar, in aſtronomy, is a ſouthern conſtellation, containing eight ſtars.

ARAB, or Arabian Horse, is the ſame as Equus.

ARABESQUE or Arabesk, is ſomething done after the manner of the Arabians.

Arabeſque, Groteſque, and Moreſque, are terms applied to paintings, in which there are no human or animal figure but which conſiſt wholly of imaginary foliages, plants, ſtalks, &c.

The words take their riſe from hence, that the Moors, Arabs, and other Mahometans, uſe theſe kinds of ornaments; their religion forbidding them to make any images or figures of men or animals.

ARABIC, is ſynonymous with Arabian, which, in a general ſenſe, includes every thing that partakes of the country of Arabia, or the Arabs. Moſt authors ſuppoſe the language to have originated from the Hebrew.

ARABICI, in eccleſiaſtical hiſtory, were a ſect who ſprung up in Arabia, about the year 207, whoſe diſtinguiſhing tenet was, that the ſoul died with the body, and alſo roſe again with it.

ARABIS, baſtard tower-muſtard, in botany, a genus of the ſiliquoſa order, belonging to the tetradynamia claſs of plants; and in the natural method ranking under the 39th order, Siliquoſæ. The generic mark conſiſts in four nectiferous glands, which lie on the inſide of each leaf of the calyx.

There are 8 ſpecies; but none of them remarkable for their beauty or other properties. Only one of theſe, the thaliana or mouſe-ear, is a native of Britain.

ARABIS, in botany, is a ſynonyme of the town muſtard.

ARABISM, *Arabiſmus*, an idiom peculiar to the Arabic language.

ARABIST, ſignifies a perſon ſkilled in the learning and languages of the Arabians.

ARABLE Lands, imply thoſe which are fit for tillage, or have been formerly tilled.

ARABUM Lepra, in the deſcription of maladies, is ſynonymous with Leproſy.

ARACARI, in zoology, is a ſynonyme of the Brazilian woodpecker.

ARACHIS, in botany, is a genus of the diadelphia order, belonging to the decandria claſs of plants; and, in the natural method, ranking under the 32d order, Papillionacæ. There is only one ſpecies, the hypogæa, an annual plant, and a native of Braſil and Peru. The ſtalks are long, trail upon the ground, and are furniſhed with winged leaves, compoſed of four hairy lobes each. The flowers are produced ſingly on long pedunculs; they are yellow, of the pea kind, and each contains ten round ſhaped ſtamina, nine of which are tied together, and the upper one ſtands off.

In the centre is an awl-ſhaped ſtylus, crowned with a ſimple ſtigma. The germen is oblong, and becomes an oval oblong pod, containing two or three oblong blunt ſeeds.

This plant is cultivated in all the American ſettlements for the ſeeds, which make a conſiderable part of the food of the ſlaves. The manner of perfecting them is very ſingular: for as the flowers fall off, the young pods are forced into the ground by a natural motion of the ſtalks, and there they are entirely buried, and not to be diſcovered without digging for them; from whence they have taken the name of ground-nuts.

ARACHNE, in fabulous hiſtory, was a young maid of Lydia, ſaid to have been the inventreſs of ſpinning.

ARACHNOIDES, in anatomy, is an appellation given to ſeveral membranes; as the tunic of the cryſtalline humour of the eye, the external lamina of the pia mater, and one of the coverings of the ſpinal marrow.

ARACK, Abrack, or Rack, a ſpirituous liquor imported from the Eaſt Indies, uſed by way of dram and in punch.

The word arack, is an Indian name for ſtrong waters of all kinds. But what we underſtand by arack, is really no other than a ſpirit procured by diſtillation from a vegetable juice called toddy, which flows by inciſion out of the cocoa-nut tree, like the birch-juice procured among us.

Toddy is a pleaſant drink by itſelf, when new, and purges thoſe who are not uſed to it; and, when ſtale, it is heady, and makes good vinegar.

The Goa arack is made from toddy, the Batavia arack from rice and ſugar; and there is likewiſe a kind of ſhrub from which arack is made.

The Parier arack made at Madraſs, and the Columbo and Quilone arack at other places, being fiery hot ſpirits, are little valued by the Europeans, and therefore rarely imported; though highly prized among the natives.

The manner of making the Goa arack is thus: The juice of the trees is not procured in the way of tapping, as we do; but the operator provides himſelf with a parcel of earthern pots, with bellies and necks like our ordinary bird-bottles: he then makes faſt a number of theſe to his girdle, and any way elſe that he commodiouſly can about him.

Thus equipped, he climbs up the trunk of a cocoa tree; and when he comes to the boughs, he takes out his knife, and cutting off one of the ſmall knots or buttons, he applies the mouth of the bottle to the wound, faſtening it to the bough with a bandage; in the ſame manner he cuts off other buttons, and faſtens on his pots, till the whole number is uſed: this is done in the evening, and deſcending from the tree, he leaves them till the next morning; when he takes off the bottles, which are moſtly filled, and empties the juice into the proper receptacle.

This is repeated every night, till a ſufficient quantity is produced; and the whole being then put together, is left to ferment, which it ſoon does.

When the fermentation is over, and the liquor or waſh is become a little tart, it is put into the ſtill, and a fire being made, the ſtill is ſuffered to work as long as that which comes over has any conſiderable taſte of ſpirit.

The liquor thus procured is the low wine of arack; and this is ſo poor a liquor, that it will ſoon corrupt and ſpoil, if not diſtilled again, to ſeparate ſome of its phlegm; they therefore immediately after pour back this low wine into the ſtill, and rectify it to that very weak kind of proof-ſpirit, in which ſtate we find it. The arack we meet with, notwithſtanding its being of a proof-teſt, according to the way of judging by the crown of bubbles on it, holds but a ſixth, and ſometimes but an eighth, part of an alcohol or pure ſpirit; whereas our other ſpirits, when they ſhow that proof, are generally eſteemed to hold one half pure ſpirit.

There is a paper of obſervations on arack, in the Melanges d'Hiſtoire Natur. tome v. p. 302. By fermenting, diſtilling, and rectifying the juice, of the American maple, which has much the ſame taſte as that of the cocoa, the author ſays, he made arack not in the leaſt inferior to any that comes from the Eaſt-Indies; and thinks the juice of ſycamore and of the birch trees would equally anſwer the end.

Beſides the common ſorts of Goa and Betavia arack, there are two others leſs generally known; theſe are the bitter arack and the black arack.

Arack is alſo the name of a ſpirituous liquor made by the Tartars of Tunguſia, of mare's milk, left to ſour, and afterwards diſtilled twice or thrice between two earthen pots cloſely ſtopped, from whence the liqour runs through a ſmall wooden pipe. It is more intoxicating than brandy.

ARACUS, in botany, is a ſynonyme of the ſtrangle, or wild vetch, common to this country, in hedges and on banks, and in corn-fields.

ARACUCUS Aromaticus, in natural hiſtory, implies the ſame as Vanilla, which is a principal ingredient in the making of chocolate.

ARADOS, in medicine, denotes any ſort of perturbation occaſioned by a derangement of the animal ſyſtem, including every cauſe in the liſt of malady.

ARÆOMETER, an inſtrument wherewith to meaſure the denſity or gravity of fluids.

The aræometar, or water-poiſe, is uſually made of glaſs; conſiſting of a round hollow ball, which terminates in a long ſlender neck hermetically ſealed at top; there being firſt as much running mercury put into it as will ſerve to balance or keep it ſwimming in an erect poſition.

The ſtem is divided into degrees by the depth of its deſcent into any liquor, the lightneſs of that liquor is concluded: for that fluid in which it ſinks leaſt muſt be heavieſt; and that in which it ſinks loweſt, lighteſt.

M. Homberg has invented a new aræometer, deſcribed in Phil. Tranſact. N° 262, thus: *A* is a glaſs bottle or matraſs, with ſo ſlender a neck that a drop of water takes up in it about five or ſix lines, or half of an inch. Near that neck is a ſmall capillary tube *D*, about ſix inches long, and parallel to the neck. To fill the veſſel, the liquor is poured in at the mouth *B*, (which is widened to receive a tunnel), till it run out at *D*, that is, till it riſe in the neck to the mark *C*, by which means you have always the ſame bulk or quantity of liqour; and conſequently, by means of the balance, can eaſily tell, when different liqours fill it, which weighs moſt, or is moſt intenſely heavy.

Great regard is to be had in theſe trials to the ſeaſon of the year, and degree of heat and cold in the weather; becauſe ſome liqours rarefy with heat and condenſe with cold more than others, and accordingly take up more or leſs room.

By means of this inſtrument, the ingenious author has made a table to ſhow the different weights of the ſame bulk of the moſt conſiderable chemical liquors both in ſummer and winter, as follows:

The aræometer full of	Weighed in ſummer.			—In winter.		
	oz.	*dr.*	*gr.*	*oz.*	*dr.*	*gr.*
Quickſilver	11	00	06	11	00	32
Oil of tartar	01	03	08	01	03	31
Spirit of urine	01	00	32	01	00	43
Oil of vitriol	01	03	58	01	04	03
Spirit of nitre	01	01	40	01	01	70
Spirit of ſalt	01	00	39	01	00	47
Aquafortis	01	01	38	01	01	55
Vinegar	00	07	55	00	07	60
Spirit of wine	00	06	47	00	06	61
River water	00	07	53	00	07	57
Diſtilled water	00	07	50	00	07	54

The inſtrument itſelf weighed, when empty, one dram twenty-eight grains.

ARÆOPAGUS, is the ſame as Areopagus.

ARÆOSTYLE, in architecture, is a term uſed by Vitruvius, to ſignify the greateſt interval which can be made between columns.

ARÆOTICS, in medicine, are remedies which rarefy the humours, and render them eaſy to be carried off by the pores of the ſkin.

ARAF, or **Alraf**, in the Mahometan theology, implies a partition wall which is ſaid to divide paradiſe from hell.

ARAFAH, in chronology, ſignifies the ninth day of the laſt month of the Arabic year, named Dhoulhegiat; on which the pilgrims of Mecca perform their devotions on a neighbouring mountain called Arafat.

ARAIGNEE, in fortification, implies a branch of a mine ſprung near the walls of a fortreſs, with a gallery to retire when the train is laid for execution.

ARALIA, in huſbandry, implies fallowed fields for early grain, ſuch as wheat or bere.

Aralia, in law, denotes the parcels of ground which are reputed arable; whence the equitable mode of taxation, at ſo much per acre, is now adopted in finance, as unprofitable lands bear no proportion of the ceſs or impoſt.

Aralia, the angelica tree, a genus of the pentagynia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 36th order, Hederaceæ. The eſſential characters are: the involucum is an umbella; the calyx is quinquedentated, and above the fruit; the corolla conſiſts of five petals; and the berry has five ſeeds.

There are five ſpecies of aralia, all natives of the Indies. The principal are,

1. The nudicaulis, having a naked ſtalk. This grows three or four feet high; the leaves have two large trifoliate lobes, which are ſawed on their edges. The flower-ſtalks ariſe between theſe, immediately from the root, and are terminated by round umbels of ſmall four-leaved flowers of a whitiſh colour. The roots of this ſpecies were brought over from North America, and ſold here for ſarſaparilla, and it is ſtill uſed as ſuch by the inhabitants of Canada; though it is very different from the true ſort.

2. The ſpinoſa, with a prickled ſtem, is a very ornamental ſhrub, and a native of Virginia. The height to which this tree will grow, if the ſoil and ſituation wholly agree with it, is about twelve feet; and the ſtem, which is of a dark brown colour, is defended by ſharp ſpines, which fall off; even the leaves, which are branching, and compoſed of many wings, and are of a pleaſant green colour, have theſe defenders, which are both crooked and ſtrong, and ſtand as guards to them till the leaves fall off in the autumn. The flowers are produced in large umbels from the ends of the branches: they are of a greeniſh yellow colour; and their general characters indicate their ſtructure. They make their appearance the end of July or beginning of Auguſt; but are not ſucceeded by ripe ſeeds in our gardens.

ARANEA, the ſpider; a genus of inſects belonging to the order of aptera, or inſects without wings. All the ſpecies of ſpiders have eight legs, with three joints in each, and terminating in three crooked claws; they have eight eyes, two before, two behind, and the reſt on the ſides of the head. In the fore-part of the head, at the mouth, there is a pair of ſharp crooked claws or forceps: theſe ſtand horizontally; and, when not exerted for uſe, are concealed in two caſes contrived for their reception, in which they fold like a claſp-knife, and there lie between two rows of teeth. A little below the point of each claw, there is a ſmall hole, through which Leewenhoek ſuppoſes the ſpider emits a kind of poiſon. Theſe claws are the weapons with which they kill flies, &c. for their food. The belly or hinder part is ſeparated from the head and breaſt by a ſmall thread-like tube. The ſkin or outer ſurface is a hard poliſhed cruſt.

Spiders have five tubercles or nipples at the extremity of the belly, whoſe apertures they enlarge or contract at pleaſure. It is through theſe apertures that they ſpin a gluey ſubſtance with which their bellies are full. They fix the end of their threads by applying theſe nipples to any ſubſtance, and the thread lengthens in proportion as the animal recedes from it. They can ſtop the iſſuing of the threads by contracting the nipples, and re-aſcend by means of the claws on their feet, much in the ſame manner as ſome men warp up a rope. When the common houſe-ſpider begins her webs, ſhe generally chooſes a place where there is a cavity, ſuch as the corner of a room, that ſhe may have a free paſſage on each ſide, to make her eſcape in caſe of danger. Then ſhe fixes one end of her thread to the wall, and paſſes on to the other ſide dragging the thread along with her (or rather the thread follows her as ſhe proceeds), till ſhe arrives at the other ſide, and there fixes the other end of it. Thus ſhe paſſes and repaſſes, till ſhe has made as many parallel threads as ſhe thinks neceſſary for her purpoſe. After this, ſhe begins again and croſſes theſe by other parallel threads, which may be called the woof. Theſe are the toils or ſnares which ſhe prepares for entangling flies, and other ſmall inſects, which happen to light upon it. But, beſides this large web, ſhe generally weaves a ſmall cell for herſelf, where ſhe lies concealed watching for her prey. Betwixt this cell and the large web ſhe has a bridge of threads, which, by communicating with the threads of the large one, both give her early intelligence when any thing touches the web, and enables her to paſs quickly in order to lay hold of it. There are many other methods of weaving peculiar to different ſpecies of ſpiders; but as they are with a hand-vice hold the back of the plate over a chaffing-diſh of charcoal fire, till it become ſo hot as to give pain upon being touched with the back of the hand; and the powder which adhered to the greaſe will now be fixed to the plate.

The plate being then ſuffered to cool, take turpentine varniſh mixed with ivory black; and with a hair-pencil dipt in it, cover all the lights or places where there is no work or ſhades. A rim or border of bees-wax is now to be raiſed round the plate: then having reduced the aquafortis to a proper ſtrength by vinegar or water, you pour it on, and let it ſtand five minutes for the firſt or lighteſt ſhade: after which, pour it off; and having waſhed the plate with water, ſet it on edge to dry: then with the varniſh ſtop up your light ſhades, pour on the equafortis for the ſecond tint, and let it ſtand five minutes more; proceeding in the ſame manner for every tint till you produce the darkeſt ſhades. If a bold open ground is wanted in any part, this requires an after-operation.

The ground muſt be laid as the other, by ſifting on the powder; this powder is to be much coarſer, and the plate muſt be much more heated, in order that the particles of the powder may ſpread, and form ſmall circles: even good clean roſin will do by itſelf.

In etching landſcapes, the ſky and diſtant objects are alſo performed by a ſecond operation, and the powder is ſifted upon the plate with a finer ſieve.

If the trees or any part of the fore-ground require to be higher finiſhed, the plate muſt be entirely cleanſed from greaſe with bread, and a ground laid in the common way of etching; when you may finiſh as highly and neatly as you pleaſe with the needle or point, by ſtippling with dots, and biting up thoſe parts, or by a r ling-wheel.

This art is kept as ſecret as poſſible by thoſe who practiſe it; and it is believed that no particular explanation or directions, before the preſent, except by one author, have been communicated to the public.

AQUEOUS, in a general ſenſe, implies a thing partaking of the nature of water.

AQUILA, in ornithology, a ſynonyme of the eagle.

Aquila, the eagle, in aſtronomy, is a conſtellation of the northern hemiſphere; uſually joined with Antinous. The ſtars in the conſtellation Aquila and Antinous, in Ptolemy's catalogue, are 15; in Ticho's, 19; in Heveius's, 42; in the Britannic catalogue 71.

Aquila, in chemiſtry, expreſſes ſynonymies of the ſeveral operations and ſubſtantives which are occaſionally joined to this epithet.

AQUILEGIA, columbine, a genus of the pentagynia order, belonging to the polyandria claſs of plants; and, in the natural method, ranking under the 26th order, Multiſiliquæ. It has no calyx; the petals are five, with a horn-like nectarium inſerted between each; and there are five ſeparate capſules. There are four ſpecies:

1. The vulgaris, or wild columbine, with blue flowers, grows wild in England.

2. The alpina, with long oval flowers, grows naturally in Yorkſhire.

3. The inverſa, or garden columbine; there are great varieties, both in colour, fulneſs of the flowers, and form. Theſe are commonly called roſe-columbines; the colours are cheſnut, blue, red, and white, and ſome are finely variegated with two colours.

4. The canadenſis, or Canada columbine, preſerved in the gardens of the curious, though not at all remarkable for its beauty.

Theſe plants are all propagated by ſowing the ſeeds, or parting the old roots; but the former method is chiefly practiſed, for the old roots are very apt to degenerate.

Columbine has been looked upon as aperient; and was formerly in great eſteem among the common people for throwing out the ſmall-pox and meaſles.

AQUILICIUM, or Aquiliciana, in Roman antiquity, were ſacrifices performed in times of exceſſive drought, to obtain rain of the gods.

AQUILIFEER, in the Roman armies, denoted the officer who carried the ſtandard on which the eagle was repreſented.

AQUILINE, denotes ſomething reſembling an eagle; thus, an aquiline noſe is one bent ſomewhat like an eagle's beak.

AQUILUS, among the ancients, was a dark or duſky colour, approaching to black.

AQUIMINARIUM, in antiquity, is a kind of luſtral veſſel, in which the Romans carried their holy water for expiation, and other religious offices.

AQUIQUI, a ſynonyme of the king monkey of Brazil, in South America,

ARA Thuribuli, or the Altar of Incence, in aſtronomy, a ſouthern conſtellation, not viſible in our hemiſphere, conſiſting of nine ſtars.

Ara, or Altar, in aſtronomy, is a ſouthern conſtellation, containing eight ſtars.

ARAB, or Arabian Horse, is the ſame as Equus.

ARABESQUE or Arabesk, is ſomething done after the manner of the Arabians.

Arabeſque, Groteſque, and Moreſque, are terms applied to paintings, in which there are no human or animal figure but which conſiſt wholly of imaginary foliages, plants, ſtalks, &c.

The words take their riſe from hence, that the Moors, Arabs, and other Mahometans, uſe theſe kinds of ornaments; their religion forbidding them to make any images or figures of men or animals.

ARABIC, is ſynonymous with Arabian, which, in a general ſenſe, includes every thing that partakes of the country of Arabia, or the Arabs. Moſt authors ſuppoſe the language to have originated from the Hebrew.

ARABICI, in eccleſiaſtical hiſtory, were a ſect who ſprung up in Arabia, about the year 207, whoſe diſtinguiſhing tenet was, that the ſoul died with the body, and alſo roſe again with it.

ARABIS, baſtard tower-muſtard, in botany, a genus of the ſiliquoſa order, belonging to the tetradynamia claſs of plants; and in the natural method ranking under the 39th order, Siliquoſæ. The generic mark conſiſts in four nectiferous glands, which lie on the inſide of each leaf of the calyx.

There are 8 ſpecies; but none of them remarkable for their beauty or other properties. Only one of theſe, the thaliana or mouſe-ear, is a native of Britain.

ARABIS, in botany, is a ſynonyme of the town muſtard.

ARABISM, *Arabiſmus*, an idiom peculiar to the Arabic language.

ARABIST, ſignifies a perſon ſkilled in the learning and languages of the Arabians.

ARABLE Lands, imply thoſe which are fit for tillage, or have been formerly tilled.

ARABUM Lepra, in the deſcription of maladies, is ſynonymous with Leproſy.

ARACARI, in zoology, is a ſynonyme of the Brazilian woodpecker.

ARACHIS, in botany, is a genus of the diadelphia order, belonging to the decandria claſs of plants; and, in the natural method, ranking under the 32d order, Papillionacæ. There is only one ſpecies, the hypogæa, an annual plant, and a native of Braſil and Peru. The ſtalks are long, trail upon the ground, and are furniſhed with winged leaves, compoſed of four hairy lobes each. The flowers are produced ſingly on long pedunculs; they are yellow, of the pea kind, and each contains ten round ſhaped ſtamina, nine of which are tied together, and the upper one ſtands off.

In the centre is an awl-ſhaped ſtylus, crowned with a ſimple ſtigma. The germen is oblong, and becomes an oval oblong pod, containing two or three oblong blunt ſeeds.

This plant is cultivated in all the American ſettlements for the ſeeds, which make a conſiderable part of the ſood of the ſlaves. The manner of perfecting them is very ſingular: for as the flowers fall off, the young pods are forced into the ground by a natural motion of the ſtalks, and there they are entirely buried, and not to be diſcovered without digging for them; from whence they have taken the name of ground-nuts.

ARACHNE, in fabulous hiſtory, was a young maid of Lydia, ſaid to have been the inventreſs of ſpinning.

ARACHNOIDES, in anatomy, is an appellation given to ſeveral membranes; as the tunic of the cryſtalline humour of the eye, the external lamina of the pia mater, and one of the coverings of the ſpinal marrow.

ARACK, Abrack, or Rack, a ſpirituous liquor imported from the Eaſt Indies, uſed by way of dram and in punch.

The word arack, is an Indian name for ſtrong waters of all kinds. But what we underſtand by arack, is really no other than a ſpirit procured by diſtillation from a vegetable juice called toddy, which flows by inciſion out of the cocoa-nut tree, like the birch-juice procured among us.

Toddy is a pleaſant drink by itſelf, when new, and purges thoſe who are not uſed to it; and, when ſtale, it is heady, and makes good vinegar.

The Goa arack is made from toddy, the Batavia arack from rice and ſugar; and there is likewiſe a kind of ſhrub from which arack is made.

The Parier arack made at Madraſs, and the Columbo and Quilone arack at other places, being fiery hot ſpirits, are little valued by the Europeans, and therefore rarely imported; though highly prized among the natives.

The manner of making the Goa arack is thus: The juice of the trees is not procured in the way of tapping, as we do; but the operator provides himſelf with a parcel of earthern pots, with bellies and necks like our ordinary bird-bottles: he then makes faſt a number of theſe to his girdle, and any way elſe that he commodiouſly can about him.

Thus equipped, he climbs up the trunk of a cocoa tree; and when he comes to the boughs, he takes out his knife, and cutting off one of the ſmall knots or buttons, he applies the mouth of the bottle to the wound, faſtening it to the bough with a bandage; in the ſame manner he cuts off other buttons, and faſtens on his pots, till the whole number is uſed: this is done in the evening, and deſcending from the tree, he leaves them till the next morning; when he takes off the bottles, which are moſtly filled, and empties the juice into the proper receptacle.

This is repeated every night, till a ſufficient quantity is produced; and the whole being then put together, is left to ferment, which it ſoon does.

When the fermentation is over, and the liquor or waſh is become a little tart, it is put into the ſtill, and a fire being made, the ſtill is ſuffered to work as long as that which comes over has any conſiderable taſte of ſpirit.

The liquor thus procured is the low wine of arack; and this is ſo poor a liqour, that it will ſoon corrupt and ſpoil, if not diſtilled again, to ſeparate ſome of its phlegm; they therefore immediately after pour back this low wine into the ſtill, and rectify it to that very weak kind of proof-ſpirit, in which ſtate we find it. The arack we meet with, notwithſtanding its being of a proof-teſt, according to the way of judging by the crown of bubbles on it, holds but a ſixth, and ſometimes but an eighth, part of an alcohol or pure ſpirit; whereas our other ſpirits, when they ſhow that proof, are generally eſteemed to hold one half pure ſpirit.

There is a paper of obſervations on arack, in the Melanges d'Hiſtoire Natur. tome v. p. 302. By fermenting, diſtilling, and rectifying the juice, of the American maple, which has much the ſame taſte as that of the cocoa, the author ſays, he made arack not in the leaſt inferior to any that comes from the Eaſt-Indies; and thinks the juice of ſycamore and of the birch trees would equally anſwer the end.

Beſides the common ſorts of Goa and Betavia arack, there are two others leſs generally known; theſe are the bitter arack and the black arack.

ARACK is alſo the name of a ſpirituous liquor made by the Tartars of Tunguſia, of mare's milk, left to ſour, and afterwards diſtilled twice or thrice between two earthen pots cloſely ſtopped, from whence the liqour runs through a ſmall wooden pipe. It is more intoxicating than brandy.

ARACUS, in botany, is a ſynonyme of the ſtrangle, or wild vetch, common to this country, in hedges and on banks, and in corn-fields.

ARACUCUS AROMATICUS, in natural hiſtory, implies the ſame as Vanilla, which is a principal ingredient in the making of chocolate.

ARADOS, in medicine, denotes any ſort of perturbation occaſioned by a derangement of the animal ſyſtem, including every cauſe in the liſt of malady.

ARÆOMETER, an inſtrument wherewith to meaſure the denſity or gravity of fluids.

The aræometar, or water-poiſe, is uſually made of glaſs; conſiſting of a round hollow ball, which terminates in a long ſlender neck hermetically ſealed at top; there being firſt as much running mercury put into it as will ſerve to balance or keep it ſwimming in an erect poſition.

The ſtem is divided into degrees by the depth of its deſcent into any liquor, the lightneſs of that liquor is concluded: for that fluid in which it ſinks leaſt muſt be heavieſt; and that in which it ſinks loweſt, lighteſt.

M. Homberg has invented a new aræometer, deſcribed in Phil. Tranſact. N° 262, thus: *A* is a glaſs bottle or matraſs, with ſo ſlender a neck that a drop of water takes up in it about five or ſix lines, or half of an inch. Near that neck is a ſmall capillary tube *D*, about ſix inches long, and parallel to the neck. To fill the veſſel, the liquor is poured in at the mouth *B*, (which is widened to receive a tunnel), till it run out at *D*, that is, till it riſe in the neck to the mark *C*, by which means you have always the ſame bulk or quantity of liqour; and conſequently, by means of the balance, can eaſily tell, when different liqours fill it, which weighs moſt, or is moſt intenſely heavy.

Great regard is to be had in theſe trials to the ſeaſon of the year, and degree of heat and cold in the weather; becauſe ſome liqours rareſy with heat and condenſe with cold more than others, and accordingly take up more or leſs room.

By means of this inſtrument, the ingenious author has made a table to ſhow the different weights of the ſame bulk of the moſt conſiderable chemical liquors both in ſummer and winter, as follows:

The aræometer full of	Weighed in ſummer.			—In winter.		
	oz.	*dr.*	*gr.*	*oz.*	*dr.*	*gr.*
Quickſilver	11	00	06	11	00	32
Oil of tartar	01	03	08	01	03	31
Spirit of urine	01	00	32	01	00	43
Oil of vitriol	01	03	58	01	04	03
Spirit of nitre	01	01	40	01	01	70
Spirit of ſalt	01	00	39	01	00	47
Aquafortis	01	01	38	01	01	55
Vinegar	00	07	55	00	07	60
Spirit of wine	00	06	47	00	06	61
River water	00	07	53	00	07	57
Diſtilled water	00	07	50	00	07	54

The inſtrument itſelf weighed, when empty, one dram twenty-eight grains.

ARÆOPAGUS, is the ſame as AREOPAGUS.

ARÆOSTYLE, in architecture, is a term uſed by Vitruvius, to ſignify the greateſt interval which can be made between columns.

ARÆOTICS, in medicine, are remedies which rareſy the humours, and render them eaſy to be carried off by the pores of the ſkin.

ARAF, or ALRAF, in the Mahometan theology, implies a partition wall which is ſaid to divide paradiſe from hell.

ARAFAH, in chronology, ſignifies the ninth day of the laſt month of the Arabic year, named Dhoulhegiat; on which the pilgrims of Mecca perform their devotions on a neighbouring mountain called Araſat.

ARAIGNEE, in fortification, implies a branch of a mine ſprung near the walls of a fortreſs, with a gallery to retire when the train is laid for execution.

ARALIA, in huſbandry, implies fallowed fields for early grain, ſuch as wheat or bere.

ARALIA, in law, denotes the parcels of ground which are reputed arable; whence the equitable mode of taxation, at ſo much per acre, is now adopted in finance, as unprofitable lands bear no proportion of the ceſs or impoſt.

ARALIA, the angelica tree, a genus of the pentagynia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 36th order, Hederaceæ. The eſſential characters are: the involucum is an umbella; the calyx is quinquedentated, and above the fruit; the corolla conſiſts of five petals; and the berry has five ſeeds.

There are five ſpecies of aralia, all natives of the Indies. The principal are,

1. The nudicaulis, having a naked ſtalk. This grows three or four feet high; the leaves have two large trifoliate lobes, which are ſawed on their edges. The flower-ſtalks ariſe between theſe, immediately from the root, and are terminated by round umbels of ſmall four-leaved flowers of a whitiſh colour. The roots of this ſpecies were brought over from North America, and ſold here for ſarſaparilla, and it is ſtill uſed as ſuch by the inhabitants of Canada; though it is very different from the true ſort.

2. The ſpinoſa, with a prickled ſtem, is a very ornamental ſhrub, and a native of Virginia. The height to which this tree will grow, if the ſoil and ſituation wholly agree with it, is about twelve feet; and the ſtem, which is of a dark brown colour, is defended by ſharp ſpines, which fall off; even the leaves, which are branching, and compoſed of many wings, and are of a pleaſant green colour, have theſe defenders, which are both crooked and ſtrong, and ſtand as guards to them till the leaves fall off in the autumn. The flowers are produced in large umbels from the ends of the branches: they are of a greeniſh yellow colour; and their general characters indicate their ſtructure. They make their appearance the end of July or beginning of Auguſt; but are not ſucceeded by ripe ſeeds in our gardens.

ARANEA, the ſpider; a genus of inſects belonging to the order of aptera, or inſects without wings. All the ſpecies of ſpiders have eight legs, with three joints in each, and terminating in three crooked claws; they have eight eyes, two before, two behind, and the reſt on the ſides of the head. In the fore-part of the head, at the mouth, there is a pair of ſharp crooked claws or forceps: theſe ſtand horizontally; and, when not exerted for uſe, are concealed in two caſes contrived for their reception, in which they fold like a claſp-knife, and there lie between two rows of teeth. A little below the point of each claw, there is a ſmall hole, through which Leewenhoek ſuppoſes the ſpider emits a kind of poiſon. Theſe claws are the weapons with which they kill flies, &c. for their food. The belly or hinder part is ſeparated from the head and breaſt by a ſmall thread-like tube. The ſkin or outer ſurface is a hard poliſhed cruſt.

Spiders have five tubercles or nipples at the extremity of the belly, whoſe apertures they enlarge or contract at pleaſure. It is through theſe apertures that they ſpin a gluey ſubſtance with which their bellies are full. They fix the end of their threads by applying theſe nipples to any ſubſtance, and the thread lengthens in proportion as the animal recedes from it. They can ſtop the iſſuing of the threads by contracting the nipples, and re-aſcend by means of the claws on their feet, much in the ſame manner as ſome men warp up a rope. When the common houſe-ſpider begins her webs, ſhe generally chooſes a place where there is a cavity, ſuch as the corner of a room, that ſhe may have a free paſſage on each ſide, to make her eſcape in caſe of danger. Then ſhe fixes one end of her thread to the wall, and paſſes on to the other ſide dragging the thread along with her (or rather the thread follows her as ſhe proceeds), till ſhe arrives at the other ſide, and there fixes the other end of it. Thus ſhe paſſes and repaſſes, till ſhe has made as many parallel threads as ſhe thinks neceſſary for her purpoſe. After this, ſhe begins again and croſſes theſe by other parallel threads, which may be called the woof. Theſe are the toils or ſnares which ſhe prepares for entangling flies, and other ſmall inſects, which happen to light upon it. But, beſides this large web, ſhe generally weaves a ſmall cell for herſelf, where ſhe lies concealed watching for her prey. Betwixt this cell and the large web ſhe has a bridge of threads, which, by communicating with the threads of the large one, both give her early intelligence when any thing touches the web, and enables her to paſs quickly in order to lay hold of it. There are many other methods of weaving peculiar to different ſpecies of ſpiders; but as they are all intended for the ſame purpoſe, it is needleſs to give particular deſcriptions of them.

Dr. Liſter tells us, that attending cloſely to a ſpider weaving a net, he obſerved it ſuddenly to deſiſt in the mid-work; and turning its tail to the wind, it darted out a thread with great violence: this thread, taken up by the wind, was immediately carried to ſome fathoms long; ſtill iſſuing out of the belly of the animal. Afterwards by the ſpider leaped into the air, and the thread mounted her up ſwiftly. After this diſcovery, he made the like obſervation in near thirty different ſorts of ſpiders; and found the air filled with young and old, ſailing on their threads, and doubtleſs ſeizing gnats and other inſects in their paſſage, there being often manifeſt ſigns of ſlaughter, legs and wings of flies, &c. on theſe threads, as well as in their webs below. Dr. Hulſe diſcovered the ſame thing about the ſame time.

He alſo obſerves of thoſe ſailing ſpiders, that they will often dart, not a ſingle thread only, but "a whole ſheaf at once, conſiſting of many filaments; yet all of one length, all divided each from the other, and diſtinct until ſome chance either ſnap them off or entangle them. But for the moſt part you may obſerve, that the longer they grow, the more they ſpread, and appear to a diligent obſerver like the numerous rays in the tail of a blazing ſtar. As for that which carries them away in the air, ſo ſwift off-hand, it is (as I have already hinted) partly their ſudden leap; partly the length and number of the threads projected, the ſtream of the air and wind beating more forcibly upon them; and partly the poſture and management of their feet, which at leaſt, by ſome ſort of them, I have obſerved to have been uſed very like wings or oars, the ſeveral legs (like our fingers) being ſometimes cloſe joined, at other times opened, again bent, extended, &c. according to the ſeveral neceſſities and will of the ſailor. To fly they cannot be ſtrictly ſaid, they being carried into the air by external force; but they can, in caſe the wind ſuffer them, ſteer their courſe, and perhaps mount and deſcend at pleaſure: and to the purpoſe of rowing themſelves along the air, it is obſervable that they ever take their flight backwards; that is, their head looking a contrary way, like a ſculler upon the Thames. It is ſcarce credible to what height they will mount.

Mr. Ray, ſpeaking of the height ſpiders are able to fly, he ſays, "Laſt October I took notice, that the air was very full of webs; I mounted to the top of the higheſt ſteeple on the minſter, in York, and could there diſcern them exceeding high above me."

He further obſerves, that they not only thus ſhoot their heads upward, and mount with it in a line almoſt perpendicular; they alſo project them in a line parallel to the horizon, as may be ſeen by their threads running from one wall to another in a houſe, or from one tree to another in the field, and even from wall to wall acroſs gardens of conſiderable extent.

The matter of which the ſpider's threads are formed, is a viſcid juice, elaborated in the body of the animal, and emitted from papillæ ſituated at the extremity of the belly; which papillæ are furniſhed with numerous apertures that do the buſineſs of wire-drawers, as it wera, in forming the threads. Of theſe apertures, Mr. Reaumur obſerves, there are enough in the compaſs of the ſmalleſt pin's head to yield a prodigious quantity of diſtinct threads. The holes are perceived by their effects: take a large garden-ſpider ready to lay its eggs, and applying the finger on a part of its papillæ, as you withdraw that finger, it will take with it an amazing number of different threads. M. Reaumur has often counted 70 or 80 with a microſcope, but has perceived that there were infinitely more than he could tell. In effect, if he ſhould ſay that each tip of a papilla furniſhed a thouſand, he is perſuaded he would ſay much too little. The part is divided into an infinity of little prominences, like the eyes of a butterfly, &c.

Such is the tenuity of the threads in the larger ſort of ſpiders. But if we examine the young produced by thoſe, we ſhall find that they no ſooner quit their egg than they begin to ſpin. Indeed their threads can ſcarce be perceived, but the webs may: they are frequently as thick and cloſe as thoſe of houſe-ſpiders: and no wonder, there being often four or five hundred little ſpiders concurring to the ſame work. How minute muſt their holes be? the imagination can ſcarce conceive that of their papillæ! The whole ſpider is perhaps leſs than a papilla of the parent, which produced it. But there are even ſome kinds of ſpiders ſo ſmall at their birth, that they are not viſible without a microſcope. There are uſually found an infinity of theſe in a cluſter, and they only appear like a number of red points: and yet there are webs found under them, though well nigh imperceptible. What muſt be the tenuity of one of theſe threds? Mr. Leewenhock has computed that 100 of the ſingle threads of a full grown ſpider, are not equal to the diameter of the hair of his beard. He further calculates, that when young ſpiders firſt begin to ſpin, four hundred of them are not larger than one which is of a full growth; allowing which, four millions of a young ſpider's threads are not ſo big as the ſingle hair of a man's beard.

Garden-ſpiders, particularly the ſhort-legged ſpecies, yield a kind of ſilk which has by ſome been judged ſcarce inferior to that of the ſilk-worm.

The act of generation among ſpiders varies in different ſpecies. As theſe inſects prey upon each other, except during the time of their amours, they dare not come within reach of one another but with the utmoſt caution. They may ſometimes be ſeen ſtretching out their legs, ſhaking the web, and tampering with each other by a ſlight touch with the extremity of their feet; then, in a fright, dropping haſtily down their thread, and returning in a few moments to make freſh trial by feeling. When once both parties are well aſſured of the ſex they have to deal with, the approaches of their feet, in order to feel, become more frequent, confidence takes place, and the inſtant of amorous dalliance enſues. "We cannot," ſays Lyonnet, "but admire how careful they are not to give themſelves up blindly to a paſſion, or venture on an imprudent ſtep, which might become fatal to them." Liſter and Lyonnet, two accurate obſervers, ſay, that the extremity of thoſe arms, or claws, which the ſpider uſes to graſp his prey with, ſuddenly opens, as it were by a ſpring, and lets out a white body, which the male applies beneath the abdomen of the female to fulfil the wiſh of nature. In the water-ſpider, the ſexual organs are ſituated at the hinder parts of the male, are curve, and act as it were by a ſpring; thoſe of the females are diſtinct. Nature by a thouſand varied methods accompliſhes her purpoſe

Spiders frequently change their colour, which varies much, in reſpect to ſeaſon, ſex, age, &c. but they are in general more beautifully variegated in antumn; a ſeaſon not only the moſt opportune and plentiful reſpecting their prey, but the time when they arrive at their greateſt magnitude, and are in their height of vigour.

The ſpecies of aranea enumerated by naturaliſts amount to upwards of 50; of which it may here ſuffice to mention a few of the moſt remarkable.

1. The calycina, with a round pale yellow belly, and two hollow points. It lives in the cups of flowers, after the flower-leaves have fallen off; and catches bees, and other flies, when they are in ſearch of honey.

2. The avicularia, has a convex round breaſt, hollowed tranſverſely in the middle. It is a native of America, and feeds upon ſmall birds, inſects, &c. The bite of this ſpider is as venomous as that of the ſerpent.

3. The ocellata, has three pair of eyes on its thighs. It is about the ſame ſize with the tarantula, of a pale colour, with a black ring round the belly, and two large black ſpots on the ſides of the breaſt. It is a native of China.

4. The ſaccata, has an oval belly, of a duſky iron colour. It lives in the ground, and carries a ſack with its eggs where ever it goes. This ſack it glues to its belly, and will rather die than leave it behind.

5. Diadema is the largeſt ſpider which this country produces. The abdomen is of an oval form, downy, and of a ruddy yellow colour, which is very variable in different ſeaſons; being ſometimes paler, at others very dark coloured. The upper part is beautifully adorned with black and white circles and dots, having a longitudinal band in the middle, compoſed of oblong and oval-ſhaped pearl-coloured ſpots, ſo arranged as to reſemble a fillet, ſimilar to thoſe worn by the Eaſtern kings. The ground upon which this fillet and the white dots are laid, when viewed with a glaſs, and the ſun ſhining thereon, is beautiful and rich beyond all deſcription. There are varieties in colour of this ſpider when younger. It inhabits the birch-tree.

6. The cucurbitina, has a globular yellow belly, with a few black ſpots. It lives in the leaves of trees, and incloſes its eggs in a ſoft net.

7. The labyrinthica, with a duſky oval belly, a whitiſh indented line, and a forked anus. The web of this ſpecies is horizontal, with a cylindrical well or tube in the middle.

8. The fimbriata, has a black oblong belly, with a white line on each ſide, and duſky-coloured legs. It lives in water, upon the ſurface of which it runs with great ſwiftneſs.

9. The holoſericea, has an ovaliſh belly covered with a down-like velvet; at the baſe, or under part, it has two yellow ſpots. It is found in the folded leaves of plants.

10. The viatica, or wanderer, is generally of a yellow colour more or leſs deep. Sometimes it is whitiſh and rather green. The abdomen is large, broad, and almoſt ſquare. The two foremoſt pair of legs are very long, and the hinder ſhort; which makes it walk like a crab. It is found upon plants; and is a lively, active, indefatigable hunter. Without any motion of the head, which is furniſhed with immoveable eyes, it perceives all the flies that hover round about, does not ſcare them, but ſtretches over them its arms furniſhed with feathers, which prove nets in which their wings intangle. It ſits on its eggs; which it often carries about with it, wrapt up in a ball of white ſilk.

11. The aquatica, is of a livid colour, with an oval belly, and a tranſverſe line, and two hollowed points. It frequents the freſh waters of Europe. It can live on land as well as in the water, and comes often on ſhore for its food; it is diſtinguiſhable by its brightneſs. In the water its belly appears covered with a ſilver varniſh, which is only a bubble of air attached to the abdomen by means of the oily humours which tranſpire from its body, and prevent the immediate contact of the water. This bubble of air is made the ſubſtance of its dwelling, which it conſtructs under water; for it fixes ſeveral threads of ſilk, or ſuch fine matter, to the ſtalks of plants in the water; and then aſcending

to the ſurface, thruſts the hinder part of its body above water, drawing it back again with ſuch rapidity, that it attaches underneath a bubble of air, which it has the art of detaining under water, by placing it underneath the threads abovementioned, and which it binds like a covering almoſt all around the air-bubble. Then it aſcends again for another air-bubble; and thus proceeds until it has conſtructed a large aerial apartment under water, which it enters into or quits at pleaſure. The male conſtructs for himſelf one near to the female; and when love invites, he breaks through the thread walls of the female's dwelling, and the two bubbles attached to the bellies of both unite into one, forming one large nuptial chamber. The female is ſometimes laid for a whole day together ſtretched on her back, waiting for the arrival of the male, without motion, and ſeemingly as if dead. As ſoon as he enters and glides over her, ſhe ſeems to be brought to life again, gets on her legs and runs after the male, who makes his eſcape with all poſſible ſpeed. The female takes care of the young, and conſtructs ſimilar apartments on purpoſe for them. The figure of this ſpider has nothing remarkable; and would be overlooked among a crowd of curioſities, if the ſpectator be unacquainted with its ſingular art of conſtructing an aerial habitation under water, and thus uniting together the properties of both elements. It lodges during the winter in empty ſhells, which it dexterouſly ſhuts up with a web.

12. The faſciata, with yellow bands round the belly, and duſky rings on the legs, is a native of Barbary, and is as large as the thumb. It inhabits hedges and thickets: its webs have large meſhes, and it reſides in the centre. The ſnares are ſpread for large flies, waſps, drones, and even locuſts: the leſſer inſects can eſcape through the meſhes. The animal which it entangles is ſoon bound with ſtrong threads; killed by the ſpider's jaws; and partly eat, if the ſpider is hungry; the reſt is concealed under ſome neighbouring dry leaves, covered with a kind of web and a blackiſh glue in great abundance. Its larder is ſaid to be often plentifully ſtored: the young ones live in amity; but when grown up, are mortal enemies. They never meet but they fight with violence, and their battle only ends with the death of the weakeſt. The dead body is carefully ſtored in the larder. Twelve of theſe ſpiders, by way of experiment, were ſhut up together; and, after a battle of eight days, the ſtrongeſt only remained alive.

13. The tarantula, has the breaſt and belly of an aſh-colour; the legs are likewiſe aſh-coloured, with blackiſh rings on the under part; the fangs or nippers are red on the inner ſide, the reſt being blackiſh: two of its eyes are larger than the others, and placed in the front; four other eyes are placed in a tranſverſe direction towards the mouth; the other two are nearer the back: it has two antennæ or feelers. It is a native of Italy, Cyprus, Barbary, and the Eaſt Indies. It lives in bare fields, where the lands are fallow, but not very hard. Theſe ſpiders do not live quite a year. In July they ſhed their ſkin, and proceed to propagation; which, from a mutual diſtruſt, as they frequently devour one another, is a work undertaken with great circumſpection. They lay about ſeven hundred and thirty eggs, which is hatched in the ſpring; but the parent does not live to ſee her progeny. The Ichneumon fly is their moſt formidable enemy.

The bite of the tarantula is falſely repreſented to occaſion an inflammation in the part, which in a few hours brings on ſickneſs, difficulty of breathing, and univerſal faintneſs. The perſon afterwards is affected with a delirium, and ſometimes is ſeized with a deep melancholy. The ſame ſymptoms return annually, in ſome caſes, for ſeveral years; and at laſt terminate in death. Muſic, it has been pretended, is the only cure. A muſician is brought, who tries a variety of airs, till at laſt he hits upon one that urges him to dance; the violence of which exerciſe produces a proportionable agitation of the vital ſpirits, attended with a conſequent degree of perſpiration, the conſequence of which is in general a cure. Such are the circumſtances that have been generally related, and long credited, concerning the bite of this animal. Kircherus, in his Muſurgia, gives a very particular account of the ſymptoms and cure, illuſtrated by hiſtories of caſes. Among theſe, he mentions a girl, who being bitten by this inſect, could be cured only by the muſic of a drum. He then proceeds to relate, that a certain Spaniard, truſting to the efficacy of muſic in the cure of the frenzy occaſioned by the bite of the tarantula, ſubmitted to be bitten on the hand by two of theſe creatures, of different colours, and poſſeſſed of different qualities. The venom was no ſooner diffuſed about his body, than the ſymptoms of the diſorder began to appear; upon which harpers, pipers, and other muſicians, were ſent for, who by various kinds of muſic endeavoured to rouſe him from that ſtupor into which he was fallen: but here it was obſerved that the bites of the two inſects had produred contrary effects; for by one he was incited to dance, and by the other he was reſtrained therefrom; and in this conflict of nature the patient expired. The ſame account is given in his Phonurgia Nova, with the addition of a cut repreſenting the inſect in two poſitions, the patient in the action of dancing, together with the muſical notes of the tune or air by which in one inſtance the cure was effected.

In his Muſurgia, this author, attempting mechanically to account for the cure of the bite of the tarantula by muſic, ſays of the poiſon, That it is ſharp, gnawing, and bilious; and that it is received and incorporated into the medullary ſubſtance of the fibres. With reſpect to the muſic, he ſays, That the ſounds of chords have a power to rarefy the air to a certain harmonical pitch; and that the air thus rarefied, penetrating the pores of the patient's body, affects the muſcles, arteries, and minute fibres, and incites him to dance; which exerciſe begets a perſpiration, in which the poiſon evaporates.

Unſatisfactory as this theory appears, the belief of this ſtrange phenomenon has prevailed among the ableſt of modern phyſicians. Sir Thomas Brown, ſo far from diſputing it, ſays, That ſince many atteſt the fact from experience, and that the learned Kircherus hath poſitively averred it, and ſet down the ſongs and tunes ſolemnly uſed for the cure of the diſeaſe, and ſince ſome alſo affirm that the tarantula itſelf will dance at the ſound of muſic, he ſhall not at all queſtion it.

Baglivi, a native of Apulia, the country where the tarantula is produced, has written a diſſertation *De anatomia, morſu, et effectibus tarantulæ*. In this he deſcribes the region of Apulia where the tarantula is produced, with the anatomy and figure of the inſect and its eggs, illuſtrated by an engraving; he mentions particularly the ſymptoms that follow from the bite, and the cure of the diſeaſe by muſic, with a variety of hiſtories of cures thus wrought.

Ludovicus Valetta, a Celeſtine monk of Apulia, publiſhed at Naples, in the year 1706, a treatiſe upon this ſpider, in which he not only anſwers the objections of thoſe who deny the whole thing, but gives, from his own knowledge, ſeveral inſtances of perſons who had ſuffered this way.

The honourable Mr. Robert Boyle, in his treatiſe of Languid and Unheeded Motions, ſpeaking of the bite of the tarantula, and the cure of the diſeaſe which follows it by means of muſic, ſays, That, having himſelf had ſome doubts about the matter, he was, after ſtrict inquiry, convinced that the relations in the main were true.

Laſtly, Dr. Mead, in his Mechanical Account of Poiſons, has given an eſſay on the tarantula, containing the ſubſtance of the above relations, which he endeavours to confirm by his own reaſoning thereon.

Notwithſtanding the number and weight of theſe authorities, and the general acquieſcence of learned and ingenious men in the opinion that the bite of the tarantula is poiſonous, and that the cure of the diſorder occaſioned by it is effected by muſic, it is beyond doubt a miſtaken notion.

Dr. Serao, an Italian phyſician, has written an ingenious book, in which he has effectually exploded this opinion as a popular error; and in the Philoſophical Tranſactions, N° LX. for the year 1770, p. 236. is a letter from Dominico Cirillo, M. D. profeſſor of natural hiſtory in the univerſity of Naples, wherein, taking notice of Serao's book, he ſays, That having had an opportunity of examining the effects of this animal in the province of Taranto, where it is found in great abundance, he finds that the ſurpriſing cure of the bite of the tarantula by muſic has not the leaſt truth in it; and that it is only an invention of the people, who want to get a little money by dancing when they ſay the tarantiſm begins.

He adds, "I make no doubt but ſometimes the heat of the climate contributes very much to warm their imaginations, and throw them into a delirium, which may be in ſome meaſure cured by muſic; but ſeveral experiments have been tried with the tarantula, and neither men nor animals after the bite have had any other complaint than a very trifling inflammation upon the part, like that produced by the bite of a ſcorpion, which goes off by itſelf without any danger at all. In Sicily, where the ſummer is ſtill warmer than in any part of the kingdom of Naples, the tarantula is never dangerous; and muſic is never employed for the cure of the pretended tarantiſm."

Mr. Swinburn, when in the country of the tarantula, was deſirous of inveſtigating minutely every particular relative to that inſect; but the ſeaſon was not far enough advanced, and no *tarantati* (perſons bitten, or pretending to be bitten, by the tarantula) had begun to ſtir. He prevailed, however, upon a woman who had formerly been bitten, to act the part, and dance the tarantata before him. A great many muſicians were ſummoned, and ſhe performed the dance, as all preſent aſſured him, to perfection. At firſt ſhe lolled ſtupidly on a chair, while the inſtruments were playing ſome dull muſic. They touched, at length, the chord ſuppoſed to vibrate to her heart; and up ſhe ſprang with a moſt hideous yell, ſtaggered about the room like a drunken perſon, holding a handkerchief in both hands, raiſing them alternately, and moving in very true time. As the muſic grew briſker, her motions quickened, and ſhe ſkipped about with great vigour and variety of ſteps, every now and then ſhrieking very loud. The ſcene was far from pleaſant; and, at his deſire, an end was put to it before the woman was tired. Wherever the tarantati are to dance, he informs us, a place is prepared for them, hung round with bunches of graves and ribbons. The patients are dreſſed in white, with red, green, or yellow ribbons, for thoſe are their favourite colours; upon their ſhoulders they caſt a white ſcarf, let their hair fall looſe about their ears, and throw their heads as far back as they can bear it. They are exact copies of the ancient prieſteſſes of Bacchus. The orgies of that god, whoſe worſhip, under various ſymbols, was more widely ſpread over the globe than that of any other divinity, were no doubt performed with energy and enthuſiaſm by the lively inhabitants of this warm climate. The introduction of Chriſtianity aboliſhed all public exhibitions of theſe heatheniſh rites, and the women durſt no longer act a frantic part in the character of Bacchantes. Unwilling to give up ſo darling an amuſement, they deviſed other pretences; and poſſeſſion by evil ſpirits may have furniſhed them with one. Accident may alſo have led them to a diſcovery of the tarantula; and, upon the ſtrength of its poiſon, the Puglian dames ſtill enjoy their old dance, though time has effaced the memory of its ancient name and inſtitution: and this Mr. Swinburn takes to be the origin of ſo ſtrange a practice. If at any time theſe dancers are really and involuntary affected, he ſuppoſes it can be nothing more than an attack upon their nerves, a ſpecies of St. Vitus's dance; and he inclines the more to the idea, as there are numberleſs churches and places throughout theſe provinces dedicated to that ſaint.

Mr. Swinburn ſays, no perſon above the loweſt rank in life was ever ſeized with this malady, nor is there an inſtance of its cauſing death. The length of the dance, and the patient's powers of bearing ſuch exceſſive fatigue in the canicular ſeaſon, prove nothing; becauſe every day, at that time of the year, peaſants may be ſeen dancing with equal ſpirit and perſeverance, though they do not pretend to be ſeized with the tarantiſm. The illneſs may therefore be attributed to hyſterics, exceſſive heat, ſtoppage of perſpiration, and other effects of ſleeping out of doors in a hot ſummer air, which is always extremely dangerous, and ſometimes mortal, in moſt parts of Italy. Violent exerciſe may have been found to be a certain cure for this diſorder, and continued by tradition, though the date and circumſtances of this diſcovery have been long buried in oblivion; a natural paſſion for dancing, imitation, cuſtom of the country, and a deſire of raiſing contributions upon the ſpectators, are probably the real motives that inſpire the tarantati. Before Serao's experiments, the tarantula had been proved to be harmleſs, from trials made in 1693 by Clarizio, and in 1740 at Lucera by other naturaliſts.

The venom of this ſpecies of ſpider can produce no effects but ſuch as are common to all others.

ARAIGNEE, in fortification, a ſynonymous term with Gallery.

ARANEA Concha, or ſpider ſhell, in natural hiſtory, are ſpecies of the murex. The characters are, the lips are digitated; the number of fingers without rule, from 4 to 8.

ARANEUS Marinus, the ſea ſpider, a ſynonyme of the draco marinus.

ARANNEA, in metallurgy, ſignifies the pure ſilver ore adhering to the ſpar, like a cobweb: this runs down in ſmelting at the earlieſt fuſion, i. e. about 42° of heat.

ARAPAUNA, in ornithology, a ſynonyme of the macaw.

ARATO Bafaben, in aſtronomy, implies a fixed ſtar in the head of the dragon.

ARATURA Terræ, in law, denotes an homage in copyhold premiſes due to the lord of the manor, as ſervices in tillage, but more uſually denominated a yoke of oxen or kine, to prepare the fields into fallow.

ARBITRATORS, in law, ſignify two deputed judges, one for the plaintiff, and another for the defendant, but in caſe they do not agree, theſe two depute a third perſon, who is called an umpire, whoſe deciſion or award is final. The high court of chancery very frequently in matters of commercial intereſt, or mercantile tranſactions, refer to this mode of adjuſting litigated points; which is the ſoundeſt policy and greateſt wiſdom to ſettle differences, by perſons profeſſing the ſame occupations, as the perſons who are contending for a legal verdict: for it gives entire ſatisfaction, and begets confidence in the law of the land.

ARBOR, in chemiſtry, implies all ſuch chriſtallizations as reſemble the body, branches or ſtems of trees.

Hence many compoſitions in this art bear that name; deriving the epithet from whatever gives them body for ſuch production.

Arbor, in genealogy, indicates a regular diſpoſition of root, ſtock and branches, ſo as to ſhew the real conſanguinity, affinity and kindred, derived under a particular family increaſe. Theſe well conſidered, and rightly diſtributed in order of claſſification, would, no doubt, prevent many litigations in courts of law.

ARBOREOUS, in natural hiſtory, implies ſomething partaking of the nature of trees; ſuch as fungaſſes, moſſes, ivy, &c.

ARBOUR, or Bower, in gardening, denotes a kind of ſummer-houſe made in a garden, formerly much admired; but the modern taſte has now rejected them, as unwholeſome places of reſort, owing to the too great current of dephlogiſticated effluvia, which muſt neceſſarily ariſe from the ripening fruits and decaying fibres.

ARBUSCULA, in botany, is a trivial name of the elder tree; and a ſynonyme for the whole family of plants, between ſhrubs and trees.

RBUSTUM, in botanical language, implies an orchard or garden ſet with fruit trees.

ARBUTUS, or ſtrawberry tree, in botany, is a genus of the monogynja order, belonging to the decandria claſs, and in the natural order of methodical arrangement, the 18th family, bicornes.

The calyx, in five parts; the corolla ovated, and the fruit, a berry, with five cells. There are ſeven ſpecies.

1. The unedo, or common ſtrawberry tree, a native of Italy, Spain, France, and Ireland; and now common to the gardens of England, and Scotland.

There are four varieties of it; which only can be diſtinguiſhed by their ſize and colour, as produced by leſs or greater pains in culture.

They are all common to the London market, and bear the oblong, the round fruited, the red flowered, and the double bloſſomed ſtrawberries; and may each be propagated by ſeeds or cuttings.

One deſcription is nearly common to all; and their inconſiderable variation is almoſt ſufficiently ſhown in their reſpective appellations

2. The adrachne, or Oriental berry.
3. The bilberry of Arcadia.
4. The bilberry with white leaves.
5. The uva urſa, or bear berries.
6. The acadienſis, or Arcadian berry.
7. The alpina, or mountain ſtrawberry.

The method of cultivation is nearly the ſame in theſe ſpecies as that of the arbutus. However, it is allowed by the moſt experienced gardeners, that the fruit raiſed by ſeeds, are always preforable to thoſe raiſed from cuttings.

ARCA, in zoology, implies a genus of the vermes teſtacea, in the Linnæan claſſification.

ARCACORDIS, in anatomy, a ſynonyme of the pericardium.

ARCADE, in architecture, implies any opening in a wall, over which an arch is made.

ARCANGIS, in the Ottoman armies, ſignify plundering ſcouts, or privileged pillaging ſoldiers, who receive no pay till they ſignalize themſelves by harraſſing and diſtreſſing the enemy: after which they are ranked with the Janizaries.

ARCH, in geometry, implies any part of a curved line, intercepted between two points; hence, arches of a circle, which are, arches of any dimenſion leſs than a ſemicircle.

Arch, in military, or naval departments, ſignifies a concave or vault, in the form of a curve erected to ſupport ſome heavy ſtructure or paſſage.

Arch Angel, in Scripture, implies the meſſenger of God, ſent on an extraordinary occaſion. This high rank of celeſtial dignity is the ſecond order of the third hierarchy.

Arch Triumphal, in univerſal hiſtory, denotes a gate, over which an arch was erected, exactly ſemicircular, adorned with ſculpture and inſcriptions, erected in honour of thoſe heroes who have deſerved a triumph.

ARCHARD, in a mercantile phraſe, implies a bale of pickles; but in a more reſtrained ſenſe, it ſignifies an Eaſt Indian pickle, in much eſtimation throughout India.

ARCHBISHOP, the name of a church dignitary of the firſt claſs. Archbiſhops were not known in the Eaſt till about the year 320; and though there were ſome ſoon after this who had the title, yet that was only a perſonal honour, by which the biſhops of conſiderable cities were diſtinguiſhed. It was not till of late that archbiſhops became metropolitans, and had ſuffragans under them. Athanaſius appears to be the firſt who uſed the title archbiſhop, which he gave occaſionally to his predeceſſor; Gregory Nazianzen, in like manner, gave it to Athanaſius; not that either of them were entitled to any juriſdiction, or even any precedence in virtue of it. Among the Latins, Iſidore Hiſpalenſis is the firſt that ſpeaks of archbiſhops. He diſtinguiſhes four orders or degrees in the eccleſiaſtical hierarchy, viz. patriarchs, archbiſhops, metropolitans, and biſhops.

The archbiſhop, beſide the inſpection of the biſhops and inferior clergy in the province over which he preſides, exerciſes epiſcopal juriſdiction in his own dioceſe. He is guardian of the ſpiritualties of any vacant ſee in his province, as the king is of the temporalities; and exerciſes eccleſiaſtical juriſdiction in it. He is entitled to preſent by lapſe to all the eccleſiaſtical livings in the diſpoſal of his dioceſan biſhop, if not filled within ſix months. He has likewiſe a cuſtomary prerogative, upon conſecrating a biſhop, to name a clerk or chaplain to be provided for by ſuch biſhop; in lieu of which it is now uſual to accept an option. He is ſaid to be enthroned when veſted in the archbiſhopric; whereas biſhops are ſaid to be inſtalled.

The eccleſiaſtical government of England is divided into two provinces, viz. Canterbury and York. Canterbury hath the following ſuffragan biſhoprics appertaining to it, St. Aſaph, Bangor, Bath and Wells, Briſtol, Chicheſter, Litchfield and Coventry, St. David's, Ely, Exeter, Glouceſter, Hereford, Landaff, Lincoln, London, Norwich, Oxford, Peterborough, Rocheſter, Saliſbury, Wincheſter, and Worceſter. To York appertaineth the biſhopric of Carliſle, Cheſter, and Durham; to which may be added the biſhopric of Sodor and Man, whoſe biſhop is not a lord of parliament.

The archbiſhop of Canterbury had anciently, viz. till the year 1152, juriſdiction over Ireland, as well as England, and was ſtyled a *patriarch*, and ſometimes *alterius orbis papa*, and *orbis Britannici pontifex*. Matters were done and recorded in his name thus, *Anno pontificatus noſtri primo*, &c. The firſt archbiſhop of Canterbury was Auſtin, appointed by king Ethelbert, on his converſion to Chriſtianity, about the year 598. He was alſo *legatus natus*. He even enjoyed ſome ſpecial marks of royalty; as, to be patron of a biſhopric, which he was of Rocheſter; and to make knights, coin monies, &c. He is ſtill the firſt peer of England, and the next to the royal family; having precedence of all dukes and all great officers of the crown. It is his privilege, by cuſtom, to crown the kings and queens of this kingdom. He may retain and qualify eight chaplains; whereas a duke is by ſtatute allowed only ſix. He has, by common law, the power of probate of wills and teſtaments, and granting letters of adminiſtration. He has alſo a power to grant licences and diſpenſations in all caſes formerly ſued for in the court of Rome, and not repugnant to the law of God. He accordingly iſſues ſpecial licences to marry, to hold two livings, &c. and he exerciſes the right of conferring degrees. He alſo holds ſeveral courts of judicature; as, ccurt of arches, court of audience, prerogative court, and court of peculiars.

The archbiſhop of York has the like rights in his province as the archbiſhop of Canterbury. He has precedence of all dukes not of the royal blood; and of all officers of ſtate, except the lord high chancellor. He has alſo the rights of a count palatine over Hexamſhire. The firſt archbiſhop of York was Paulinus, appointed by Pope Gregory about the year 622. He had formerly juriſdiction over all the biſhops of Scotland; but in the year 1470, pope Sextus IV. created the biſhop of St. Andrew's archbiſhop and metropolitan of all Scotland.

Scotland, whilſt epiſcopacy prevailed in that country, had two archbiſhops, of St. Andrew's and Glaſgow; of which the former was accounted the metropolitan; and, even before it arrived at the dignity of an archbiſhopric, reſiſted with great ſpirit all the attempts of the archbiſhops of York in England to become the metropolitans of Scotland. The ſees of Argyle, Galloway, and the Iſles, were ſuffragans to Glaſgow; all the others in the kingdom, to St. Andrew's.

Ireland has four archbiſhops; of Armagh, Dublin, Caſhel, and Tuam; the former of whom is primate of all Ireland.

ARCHBISHOPRIC, in eccleſiaſtical geography, a province ſubject to the juriſdiction of an archbiſhop.

ARCHBUTLER, in the German empire, ſignifies the office of cup-bearer to the emperor, which is reckoned the higheſt office in the emperor's gift. This uſually belongs to the king of Bohemia.

ARCHCHAMBERLAIN, in the German empire, is an officer on an equal rank with the great chamberlain of England. This is held by the elector of Brandenburg.

ARCHCHANCELLOR, was an high officer, who in former times preceded over the ſecretaries of the court of Vienna, the capital of the German empire.

Now the office is merely honorary. The archbiſhop of Mentz has that title.

ARCHCANTOR, the chief of a chantery in the Roman catholic church.

ARCHCUNOT, a title formerly given to the earl of Flanders, on account of his great power and riches.

ARCHDEACON, an eccleſiaſtical dignitary or officer next to a biſhop, whoſe juriſdiction extends either over the whole dioceſe or only a part of it. He is uſually appointed by the biſhop himſelf; and hath a kind of epiſcopal authority, originally derived from the biſhop, but now independent and diſtinct from his. He therefore viſits the clergy; and has his ſeparate court for puniſhment of offenders by ſpiritual cenſures, and for hearing all other cauſes of eccleſiaſtical cognizance. There are 60 archdeacons in England.

ARCHDEACON's *Court*, is the moſt inferior court in the whole eccleſiaſtical polity. It is held, in the archdeacon's abſence, before a judge appointed by himſelf, and called his official, and its juriſdiction is ſometimes in concurrence with, ſometimes in excluſion of, the biſhop's court of the dioceſe. From hence, however, ſtatue 24 Hen. VIII. c. 12. there lies an appeal to that of the biſhop.

ARCHDRUID, the chief or pontiff of the antient druids.

ARCHDUKE, a title pecular to the houſe of Auſtria; all the ſons of which are archdukes, and daughters archducheſſes.

ARCHED, in a general ſenſe, implies any thing that is conſtructed, faſhioned, or formed in the ſhape of an arch.

ARCHER, in ancient military art, denotes a perſon who fought with a bow and arrows.

ARCHERS, a kind of militia or ſoldiery armed with bows and arrows. The word is formed of *arcus*, "a bow;" whence *arcuarius*, and even *arquis*, and *arquites*, as they are alſo denominated in the corrupt ſtate of the Latin tongue.

Archers were much employed in former times: but they are now laid aſide, excepting in Turkey and ſome of the Eaſtern countries; where there are companies of archers ſtill ſubſiſting in their armies, and with which they did terrible execution at the battle of Lepanto. As an exerciſe, the practice of archery is ſtill kept up in many places.

In France, the officers who attend the lieutenants de police and provoſts to make captures, ſeizures, arreſts, &c. are called *archers*; though their arms be only halberds or cambines. In this ſenſe they ſay, the *archers* of the *grand prevot de l'hotel*; of the *prevot des marchands*; the city *archers*; the *archers du guet*, or of the watch, &c. Small parties or *archers*, called alſo *gens de marechauſſee*, are continually patrolling on the great roads, to ſecure them againſt robbers. The carriages of Lyons, &c. are always eſcorted by a party of archers. To the diligence of theſe archers, or marſhal's-men, it is partly owing, that perſons now travel in all parts of France in the utmoſt ſecurity; there being fewer robbers on the highway in that whole kingdom in a year than about London in a week.

ARCHERY, the art or exerciſe of ſhooting with a bow and arrow.

In moſt nations the bow was anciently the principal implement of war, and by the expertneſs of the archers alone was often decided the fate of battles and of empires. In this iſland archery was greatly encouraged in former times, and many ſtatutes were made for the regulation thereof; whence it was that the Engliſh archers in particular became the beſt in Europe, and procured them many ſignal victories.

The Artillery Company of London, though they have long diſuſed the weapon, are the remains of the ancient fraternity of bowmen or archers.

Artillery, *artillerie*, is a French term ſignifying *archery*; as the *king's bowyer* is in that language ſtiled *artillier du roy:* and from that nation the Engliſh ſeem to have learnt at leaſt the croſs-bow archery. We therefore find that William the Conqueror had a conſiderable number of bowmen in his army at the battle of Haſtings, when no mention is made of ſuch troops on the ſide of Harold: and it is ſuppoſed that theſe Norman archers ſhot with the arbaleſt, or croſs-bow, in which formerly the arrow was placed in a groove, being termed in French a *quadrel*, and in Engliſh a *bolt*.

Of the time when ſhooting with the long bow firſt began among the Engliſh, at which exerciſe they afterwards became ſo expert, there appear no certain accounts. Their chroniclers do not mention the uſe of archery as expreſsly applied to the croſs-bow, or the long-bow, till the death of Richard I. who was killed by an arrow at the ſiege of Limoges in Guienne, which Hemmingford mentions to have iſſued from a croſs-bow. After this, which happened in 1199, there appear not upon record any notices of archery for nearly 150 years, when an order was iſſued by Edward III. in the 15th year of his reign, to the ſheriffs of moſt of the Engliſh counties for providing 500 white bows and 500 bundles of arrows, for the then intended war againſt France. Similar orders are repeated in the following years; with this difference only, that the ſheriff of Glouceſterſhire is directed to furniſh 500 painted bows as well as the ſame number of white. The famous battle of Creſſy was fought four years afterwards, in which our chroniclers ſtate that we had 2000 archers, who were oppoſed to about the ſame number of the French, together with a circumſtance which ſeems to prove, that by this time we uſed the long-bow, whilſt the French archers ſhot with the arbaleſt. The circumſtance alluded to is as follows: Previouſly to the engagement there fell a very heavy rain, which is ſaid to have much damaged the bows of the French, or perhaps rather the ſtrings of them. Now the long-bow (when unſtrung) may be moſt conveniently covered, ſo as to prevent the rain's injuring it; nor is there ſcarcely any addition to the weight from ſuch a caſe; whereas the arbaleſt is of a moſt inconvenient form to be ſheltered from the weather. As therefore, in the year 1342, orders iſſued to the ſheriffs of each county to provide 500 bows, with a proper proportion of arrows, it ſeems probable that theſe were long-bows, and not the arbaleſt.

At the above-mentioned battle, the Engliſh aſcribed their victory chiefly to the archers. The battle of Poicters was fought A. D. 1356, and gained by the ſame means.

Philip de Comines acknowledges, what our own writers aſſert, that the Engliſh archers excelled thoſe of every other nation; and Sir John Forteſcue ſays, "that the might of the realme of England ſtandyth upon archers." The ſuperior dexterity of their archers gave the Engliſh a great advantage over their capital enemies the French and Scots. The French depended chiefly on their men at arms, and the Scots on their pikemen; but the ranks of both were often thinned and thrown into diſorder by flights of arrows before they could reach their enemies.

Charles I. appears, from the dedication of a treatiſe intitled *The Bowman's Glory*, to have been himſelf an archer; and in the eighth year of his reign he iſſued a commiſſion to the chancellor, lord-mayor, and ſeveral of the privy-council, to prevent the fields near London being ſo incloſed as "to interrupt the neceſſary and profitable exerciſe of ſhooting," as alſo to lower the mounds where they prevented the view from one mark to another.

In 1682 there was a moſt magnificent cavalcade and entertainment

tainment given by the Finſbury archers, when they beſtowed the titles of "duke of Shoreditch," "marquis of Iſlington," &c. upon the moſt deſerving. Charles II. was preſent upon this occaſion; but the day being rainy, he was obliged ſoon to leave the field.

So lately as the year 1753 targets were erected in the Finſbury fields, during the Eaſter and Whitſun holidays; when the beſt ſhooter was ſtiled Captain for the enſuing year, and the ſecond Lieutenant.

As the ſhooting with the long-bow was firſt introduced in England, and practiſed almoſt excluſively for nearly two centuries, ſo it hath occaſioned a peculiar method of drawing the arrow to the ear and not to the breaſt. That this is contrary to the uſage of the ancients is very clear from their reliefs, and from the tradition of the Amazons cutting off one of their paps as it occaſioned an impediment to their ſhooting. The Finſbury archer is therefore repreſented in this attitude of drawing to the ear, both in the *Bowman's Glory*, and in the ſilver badge given by Catharine to the Artillery Company.

Henry VIII. gave the firſt charter to the Artillery Company in the 29th year of his reign, by which they are permitted to wear dreſſes of any colour except purple and ſcarlet, to ſhoot not only at marks but birds, if not pheaſants or herons, and within two miles of the royal palaces. They are alſo enjoined by the ſame charter not to wear furs of a greater price than thoſe of the martin. The moſt material privilege, however, is, that of indemnification from murder, if any perſon paſſing between the ſhooter and the mark is killed, provided the archers have firſt called out *faſt*.

Archery with the long-bow continues to be uſed as a manly exerciſe by the inhabitants of Geneva, and in many parts of Flanders; nor is it totally neglected in Great Britain. There are ſeveral ſocieties of archers in England; the chief of which are, the Woodmen of Arden, and the Toxophilite. But the moſt noted ſociety of this kind, now exiſting, is

The Royal Company of Archers in Scotland. The ancient records of this company having been deſtroyed by fire about the beginning of the preſent century, no authentic traces of their inſtitution now remain. It is ſaid that they owe their origin to the commiſſioners appointed in the reign of James I. of Scotland for enforcing and overſeeing the exerciſe of archery in different counties. Thoſe commiſſioners, who were in general men of rank and power, picking out amongſt the better ſort of people under their cogniſance the moſt expert archers, formed them into a company, and upon perilous occaſions made a preſent of their ſervices to the king as his chief body-guards; in which ſituation they often diſtinguiſhed themſelves for their loyalty, their courage, and ſkill in archery. This rank of the king's principal body-guards, the Royal Company ſtill claim within ſeven miles of the metropolis of Scotland.

Certain it is, that by an act of the privy-council of Scotland in 1677, this Company was recogniſed under the name and title of "His Majeſty's Company of Archers:" and by the ſame act a piece of plate of the value of 20l. ſterling was ordered to be given to be ſhot for by them at their annual parades called Weaponſhawings, and to be called The King's Prize.

At this period the Royal Company conſiſted, as it does at preſent, of the principal nobility and gentry of Scotland. But their unfortunate attachment to anti-revolution principles, upon that event's taking place, put almoſt a period to their exiſtence; their public parades or marches were diſcontinued, and the royal prize was with-held.

Upon the acceſſion of Queen Anne, their former ſplendor was revived; and in the year 1703, they obtained a royal charter, confirming in general terms all their former rights and privileges, and conferring others upon them. But their partiality to the family of Stuart was at various after periods the cauſe of a temporary proſperity and decline.

These unhappy differences of opinion having totally ſubſided, the Royal Company are now more numerous and flouriſhing than ever, and perhaps even more dexterous archers. His preſent Majeſty, as a mark of his royal patronage and approbation, has been pleaſed to revive the royal prize, which for the firſt time was ſhot for upon the 28th of July 1788, by a numerous and reſpectable meeting.

ARCHETYPE, in modelling, implies the firſt model of a work in order to copy it, ſo as to make another exactly like it.

In aſſaying, it denotes the ſtandard weight by which others are adjuſted.

ARCHEUS, in chemiſtry, denotes the predominating principle of things, by which their eſſential qualities are known, fixed, and determined.

ARCHIACOLYTHUS (from *αρχος*, *chief*, and *ακολȣθος*, *miniſter*) an ancient dignity in cathedral churches: the miniſters whereof were divided into four orders or degrees, viz. prieſts, deacons, ſubdeacons, and acolythi; each of which had their chiefs. The chief of the acolythi was called *archiacolythus*.

ARCHIATER, *Archiatrus*, properly denotes the chief phyſician of a prince who retains ſeveral. The word is formed of *αρχη*, *principium*, "chief;" and *ιατρος*, *medicus*, a "phyſician."

ARCHIEROSYNES, in the Grecian antiquity, a high prieſt veſted with authority over the reſt of the prieſts, and appointed to execute the more ſacred and myſterious rites of religion.

ARCHIGALLUS, in antiquity, the high-prieſt of Cybele, or the chief of the eunuch prieſts of that goddeſs, called Galli.

ARCHIGERONTES (from *αρχος*, and *γερων*, *old*), in antiquity, the chiefs or maſters of the ſeveral companies of artificers at Alexandria.

ARCHIGUBERNUS, ARCHIGUBERNETA, or ARCHIGUBERNITES, in antiquity, the commander of the imperial ſhip, or that which the emperor was aboard of.

ARCHIL, ARCHILLA, ROCELLA, ORSIELLE, in natural hiſtory, is a whitiſh moſs which grows upon rocks, in the Canary and Cape Verd iſlands, and yields a rich purple tincture, fugitive indeed, but extremely beautiful. This weed is imported to us as it is gathered. Thoſe who prepare it for the uſe of the dyer, grind it betwixt ſtones, ſo as to thoroughly bruiſe, but not to reduce it into powder; and then moiſten it occaſionally with a ſtrong ſpirit of urine, or urine itſelf mixed with quick-lime: in a few days it acquires a purpliſh red, and at length a blue colour. In the firſt ſtate it is called *Archil*; in the latter, *Lacmus* or *Litmaſe*.

The dyers rarely imply this drug by itſelf, on account of its dearneſs and the periſhableneſs of its beauty. The chief uſe they make of it is, for giving a bloom to other colours, as pinks, &c. This is effected by paſſing the dyed cloth or ſilk through hot water lightly impregnated with the archil. The bloom thus communicated ſoon decays upon expoſure to the air. Mr. Hellot informs us, that by the addition of a little ſolution of tin, this drug gives a durable dye; that its colour is at the ſame time changed towards a ſcarlet; and that it is the more permanent in proportion as it recedes the more from its natural colour.

Prepared archil very readily gives out its colour to water, to volatile ſpirits, and to ſpirit of wine; it is the ſubſtance principally made uſe of for colouring the ſpirits of thermometers. As expoſure to the air deſtroys its colour upon cloth, the excluſion of the air produces a like effect in theſe hermetically ſealed tubes, the ſpirits of large thermometers becoming in the compaſs of a few years colourleſs. M. l'Abbe Nollet obſerves (in the French Memoirs for the year 1742), that the colourleſs ſpirit, upon breaking the tube, ſoon reſumes its colour, and this for a number of times ſucceſſively; that a watery tincture of archil, included in the tubes or thermometers, loſt its colour in three days; and that, in an open deep veſſel, it became colourleſs at the bottom, while the upper part retained its colour.

A ſolution of archil in water, applied on cold marble, ſtrains it of a beautiful violet, or purpliſh blue colour, far more durable than the colour which it communicates to other bodies. Mr. du Fay ſays, he has ſeen pieces of marble ſtained with it, which in two years had ſuffered no ſenſible change. It ſinks deep into the marble, ſometimes above an inch; and at the ſame time ſpreads upon the ſurface, unleſs the edges be bounded by wax or other like ſubſtances. It ſeems to make the marble ſomewhat more brittle.

Linnæus informs us, in the Swediſh Tranſactions for the year 1742, that the true archil moſs is to be found on the weſtern coaſts of England. It has been for a conſiderable time paſt prepared by Meſſrs. Gordons at Leith from a ſpecies found in the Highlands of Scotland.

ARCHILOCHIAN, a term in poetry, applied to a ſort of verſes, of which Archilochus was the inventor, conſiſting of ſeven feet; the four firſt of which are ordinarily dactyls, though ſometimes ſpondees; the three laſt trochees, as in Horace,

Solvitur acris hyems, grata vice veris & Favoni.

ARCHIMANDRITE, in eccleſiaſtical polity, denotes the head or chief of a monaſtery and is ſynonymous with Abbot.

ARCHIPELAGO, in geography, a general term ſignifying a ſea interrupted with iſlands; it is however more eſpecially applied to that lying between Europe and Aſia, which contains the iſlands anciently called Cyclades and Sporades.

ARCHISYNAGOGUS, the chief of the ſynagogue; the title of an officer among the Jews, who preſided in their ſynagogues and aſſemblies. The number of theſe officers was not fixed, nor the ſame in all places; there being 70 in ſome, and in others only one. They are ſometimes called *princes* of the ſynagogue, and had a power of excommunicating ſuch as deſerved that puniſhment.

ARCHITECT, *Architectus*, a perſon who is poſſeſſed of an extenſive knowledge in the art of contriving and forming any compound body; particularly in the art of building; and who makes deſigns, and plans, for edifices of all denominations; and who is capable of directing the ſeveral artificers, or workmen, in the execution thereof.

The following Hiſtory *of the* Origin *and* Progreſs *of* Architecture *is the Production of Mr. Plaw, Architect,* N° 2, *Church Street, Paddington. The* Syſtem *is the Selection and Arrangement of the ſame Gentleman, taken principally from the Works of Sir William Chambers, and the moſt approved Authors on the Subject.*

A NEW SYSTEM of ARCHITECTURE.

THE importance of the profeſſion of an Architect, requires a man to be poſſeſſed of very ſuperior talents; and his practical knowledge, together with his ſtudy, very much matured: a very ingenious man of the profeſſion has frequently declared it neceſſary a perſon ſhould live three common ordinary lives to be in full poſſeſſion of all that is requiſite to make a compleat Architect: yet many bold adventurers from the dogmatic practice of meaſuring artificers works; from the bench; cabinet work and upholſtery; gardening; or a trip to Italy; that do not heſitate to aſſume that character, and to practiſe as a profeſſor; although not really poſſeſſed of either one of the numerous qualifications neceſſary to be underſtood to entitle him to the leaſt claim.

It is a ſcience of ſo extenſive a nature, that, to attain a full knowledge of it, requires the ſkill of an uncommon genius, together with much ſcientific experience, like its rival arts, Painting and Sculpture, (only with much greater variety) and not to be eaſily attained, unleſs nature is uncommonly bountiful in her aid.

Mechanical arts may be learned; and, in one branch only, it requires the ſtudy and practice of many years to become maſter of it.

There are various branches in building, and each (though not equally difficult to comprehend) has its different profeſſors; but the Architect muſt take the whole in view, and have a good general knowledge of them all.

Vitruvius, in his firſt book of Architecture, calls it a ſcience, attended with a great diverſity of ſtudy, and requires a peculiar knowledge to judge of all the branches belonging to it; that it is partly founded on Theory, and partly on Practice.

That the Theory explains and demonſtrates the convenience and proportions requiſite to form the fabric; and the practical conſiſts in the actual and continual Execution of deſigns; and *that*, when united in an Architect, makes *his* abilities the moſt accompliſhed.

Vitruvius proceeds to ſet forth what particular branches of literature are neceſſary to be known and underſtood by the Architect.

He ſays, the Architect muſt underſtand Grammar and Deſigning well; Geometry, Optics, Arithmetic, Hiſtory, Philoſophy, Muſic, Hydraulics, Phyſic, Law, Aſtronomy, &c. though he obſerves it is not poſſible to be an Ariſtarcus in grammar, an Ariſtoxenes in muſic, an Apelles in painting, a Policlete or Miron in ſculpture, or an Hippocrates in phyſic; yet he ſhould be acquainted with as much of thoſe ſciences as to render him capable of forming a judgment upon the uſes of them.

To theſe Vitruvius has added, That the Architect muſt have a ſoul great and daring, without pride or arrogance, juſt and faithful, and, what is moſt important, without avarice; for it is impoſſible that, without Honour and Fidelity, he ſhould do any thing well; he ought to be diſintereſted, not covetous of wealth, not to do any thing to ſully the reputation of an Architect, or what is unworthy of ſo honourable a profeſſion; theſe were the ſentiments of Vitruvius in the time of Auguſtus.

Although it may appear extraordinary that all theſe accompliſhments ſhould center in one man, it is abſolutely neceſſary as many of them ſhould, as poſſible, to approach towards perfection; as the Architect, without ſome knowledge of Grammar, would be contemptible in correſponding or elucidating his deſigns; nor would he be able to conſult authors on the ſubject written in other languages; conſequently, his ideas would be confined, and his taſte depraved.

Deſigning and Drawing are next eſſential to deſcribe the artiſt's ideas on paper, to his employer, and the workmen; Geometry, to conſtruct the works on true principles; Optics, to judge of effects, and the perſpective in all points of view; Arithmetic, to form calculations of the value of works, and the admeaſurement and proportions thereof; Hiſtory, to judge of the claſſical ſtyle and manner of the ancients, according to the various periods of the fluctuation of the arts; Philoſophy, to judge of ſituations proper to build upon, quality of materials, to read men, uſe policy, govern his own temper, and ſubmit himſelf to others; Muſic, to judge of ſounds, and their operations in different conſtructed rooms, and of harmoniac proportions, ſo very applicable to architectural forms; Hydraulics, to manage the neceſſary operations of water; Phyſic, to judge of ſituations and conſtructions ſuitable to the health of mankind, and that the neceſſaries of life are proper, and not wanting; Law, to make agreements, form contracts, to judge of property, and the laws relative to building; Aſtronomy, to arrange the various apartments moſt agreeably to the ſituation and courſe of the ſun, &c.

Beſide theſe, already mentioned by Vitruvius, much more practical knowledge is very eſſential, to judge well of natural and artificial foundations proper to build upon; and of the quality, quantity, and value, of all materials, neceſſary and proper to build with; viz. the Chalk, Lime, Sand, Earth, Brick, Stone, Timber, Tile, Slate, Metals, &c.

To be a good mechanic is a very great and eſſential thing; but it ſhould be blended to ſuperior taſte, to enable the deſigner to judge of effects; for, as Wotton ſays, The Architect's glory conſiſts in the deſignment and idea of the work. His ambition ſhould be to make the form triumph over the matter. A man may be a very ingenious and good mechanic, and fall ſhort of that judgment; he may alſo be in poſſeſſion of a refined taſte, and very ready at deſign, without the other requiſites; they muſt be united to make an Architect capital.

Beſide the many accompliſhments already ſpoken of, an Architect ſhould be ever watchful and attentive to the wants and neceſſaries of life, in every department that can be imagined; if to erect a dwelling, to judge of the ſuite and proportion of rooms, proper for the rank and family for whom it is intended, and the offices to the houſe, with their arrangement and fittings, in the moſt ſuitable manner for exterior ſhow, convenience, and internal concealment. The ſame alſo of buildings of a public nature; he muſt be well acquainted with the uſes, purpoſes, and intentions of the ſtructure; and here he muſt blend a ſuperior elegance of taſte, propriety, affinity, and ornament, with every domeſtic convenience for the Court, Public Offices, College, Cathedral, Theatre, Hall, Priſon, Square, Manſion, Meuſe, Bridge, &c.

I am, therefore, much inclined to agree with the profeſſional gentleman before ſpoken of, that very ſtrict *attention*, *obſervation*, and great number of years, muſt be ſpent to qualify a man to the deſerved title of an Architect.

Amongſt the Architects of Greece, Rome, France, &c. we have the following names handed down to us, as men of great ſkill and eminence in the profeſſion, to many of whoſe works the preſent age is much indebted for their beautiful ideas, judgment of proportion, elegance of ſtyle, and correctneſs of compoſition; viz. Hermogenes, Apollodorus, Tarcheſius, Pytheus, Vitruvius, Scamozzi, Serlio, Palladio, Vignola, Barbaro, Viola, Barozzio, Julius Romanus, Cataneo, Alberti, Perrault, De L'Orme, Le Clerc, Sangello, Bramant, Mich. Angelo, Mau-Clerc, Perault, Blondel, Bernini, Bullant, Cigoli, Berani, Oſio, &c.

Of Architects in England we read of the following:

GUNDULPHUS, an Architect, built the Tower of London, the Cathedral at Rocheſter, &c.

PETER OF COLECHURCH, (a curate of St. Mary Colechurch, London) rebuilt London Bridge of timber, and after deſigned and begun to build the preſent one of ſtone, in 1176, which, it is ſuppoſed, was finiſhed by ELYAS in 1209.

EDWARD FITZODO, or Edward of Weſtminſter, in the reign of Henry the third, was maſter of the works at Weſtminſter Abbey.

PETER CAVALINI, a ſculptor, was the ſuppoſed Architect who built the croſſes erected to the memory of princeſs Eleanor; he was a Roman Sculptor; and from various circumſtances he was diſcovered to be the Architect of the ſhrine of Edward the Confeſſor; he was alſo the inventor of Moſaic, and was in England about the year 1256 to 1260.

JOHN HELPSTONE built the new Tower at Cheſter 1322.

WILLIAM of WYKEHAM, born 1324, rebuilt Windſor Caſtle and Queenborough Caſtle, in Edward the third's reign; was afterward Biſhop of Wincheſter in 1367, and after Lord Chancellor of England; built and founded New College, Oxford, Wincheſter College, &c.

It is to be lamented, that this great man did not pay more regard to the ſcience, to which he owed the greatneſs of his fortune, by eſtabliſhing a foundation for the ſtudy of his own art, for the benefit of others who depended upon it.

In the reign of Edward the third, York Minſter was erected; but by whom the deſign was made, we are ignorant.

ALLAN DE WALSINGHAM was one of the Architects to the Cathedral at Ely.

In the ſame reign WILLIAM REDE, Biſhop of Chicheſter, built the firſt library of Merton College, and alſo the Caſtle at Amberley; it has been aſſerted, that Sir REGINALD BRAY, who was a Knight of the Garter, in Henry the ſeventh's reign, aſſiſted in the ceremony of laying the firſt ſtone of the Chapel at Weſtminſter; and was Architect of the chapel of St. George, at Windſor; but the authority is doubted. See the Antiquities of Windſor Caſtle, page 65.

JOHN DRUEL and ROGER KEYES were employed as Architects by Archbiſhop Chichele about 1402.

RICHARD the Carver, and BROTHER ROWSBY, a monk, were engaged on ſome repairs in the Church of St. Mary, at Stanford, in the reign of Henry the ſixth.

Mr. Walpole obſerves, That names of artiſts in theſe reigns, of which even ſo few records exiſt, are not to be expected; but one, he ſays, he has found, the particulars of whoſe work are expreſſed with ſuch rude ſimplicity, that it may not be unentertaining to the reader to peruſe them: they are extracted from a book belonging to the Church of St. Mary Ratcliffe, at Briſtol.

Memorandum:

That Maſter Cummings hath delivered the 4th day of July, in the year of our Lord, 1470, to Mr. Nicholas Bettes, vicar of Ratcliffe beforeſaid, a new Sepulchre well-gilt, and cover thereto, an image of the Creator ryſing out of the ſame Sepulchre, with all the ordinance that longeth thereto: that is to ſay,

A lath made of timber and ironwork thereto:

Item, Thereto longeth Heven, made of timber, and ſtained cloth.

Item, Hell, made of timber and iron-work, with devils, the number thirteen;

ARCHITECTURE.

Item, Four knights armed, keeping the Sepulchre, with their weapons in their hands; that is to ſay, two ſpeares, two axes, two paves *.

Item, Four pair of angels wings, for four angels, made of timber, and well painted;

Item, The Fadre, the crown and viſage, the bell with a croſs † upon it well-gilt with fine gold;

Item, The Holy Ghoſt, coming out of Heven into the Sepulchre;

Item, Longeth to the angels four chevelers ‡.

This Memorandum is copied from the Minutes of the Antiquarian Society, under the year 1736.

* *Paves:* A pave (in French *pavois* or *talevas*) is a large buckler, forming an angle in front, like the ridge of the houſe, and big enough to cover the talleſt man from head to foot.

† *The bell with the croſs:* Probably the ball or mound.

‡ *Four chevelers:* Chevelures or perukes.

Mr. CLOOS (father of Nicholas Cloos, one of the firſt Fellows of King's College, Cambridge, and afterwards Biſhop of Litchfield) was the Architect of that magnificent building; a ſtandard of beautiful Gothic, or rather Saracenic, Architecture, and Geometrical Knowledge.

Dart's Antiquities of Weſtminſter Abbey, vol. I. p. 32, ſays, The Tomb or Mauſoleum, called Henry the Seventh's Chapel, in Weſtminſter Abbey, was the work of one PETER, a Florentine, as one PETER, a Roman, made the Shrine of Edward the Confeſſor.

PETER, the Florentine abovementioned, was PIETRO TORREGGIANI, a ſculptor, of Florence.

HANS HOLBIEN, the eminent painter, in the reign of Henry the eighth, deſigned the Porch of Wilton Houſe, alſo the Gateway at Whitehall, lately pulled down, &c.

JOHN OF PADUA, an Italian, it is ſuppoſed introduced the improved ſtyle of Roman Architecture.

LAURANCE BRADSHAW, Surveyor of the King's Works.

Sir RICHARD LEA, an Architect.

THOMAS LARKE, a Surveyor of King's College, Cambridge.

JEROME DE TREVISE, an Architect, and alſo an Italian painter.

JOHN SHUTE, a Painter and Architect, publiſhed a book, in folio, 1563, called, The firſt and chief Grounds of Architecture, &c. The author was ſent to Italy in 1550, by the Duke of Northumberland, and ſupported there in his ſtudies, under the beſt Architects.

Stowe mentions one Maſter STICKELS, an excellent Architect of that time, who, in 1596, built, for a trial, a pinnace that might be taken to pieces. Chron. p. 769.

ROBERT ADAMS, Surveyor of the Queen's buildings, ſeems to have been a man of abilities; he publiſhed two plans, one is a large print of Middleburgh, dated 1588, the other of the ſame date, drawn on parchment with a pen, intituled *Thameſis deſcriptio*; ſhewing, by lines croſs the river, how far, and from whence, cannon-balls may obſtruct the paſſage of any ſhip, upon an invaſion from Tilbury to London, with proper diſtances marked for placing the guns.

THEODORE HAVENS, in 1575, built ſome Doric Frontiſpieces, and other works at Caius College, Cambridge; alſo the Monument of Doctor Caius, &c.

In the gallery of Emanuel College is an old picture with an inſcription, recording an Architect of the ſame date with the preceding.

" Effigies RODULPHI SIMONS, Architecti, &c. &c.

JOHN THORPE deſigned or improved moſt of the principal palatial edifices, erected in the reigns of Elizabeth and James the firſt; he left a folio of plans now in Lord Warwick's poſſeſſion.

ANDREW JAMESON, Architect, at Aberdeen, father of George Jameſon, a portrait painter, called the Vandyke of Scotland, 1586.

NICHOLAS STONE, born 1586, died 1647, Statuary and Architect, made a great number of family monuments.

BERNARD JANSEN, Statuary and Architect, about the ſame date.

GERARD CHRISTMAS, Architect.

JOHN SMITHSON, Architect, 1648; his ſon, a man of ſome ſkill, ſucceeded him.

BUTLER, Architect.

STEPHEN HARRISON, Architect and Joiner.

INIGO JONES, Architect to King Charles the firſt, whoſe well-known works will ever perpetuate his memory.

Sir BALTHAZAR GERBIER D'OUVILLY, of Antwerp, Architect and Painter, publiſhed a book in 1662, at London, a ſmall diſcourſe on magnificent buildings, dedicated to the King; and another, intituled, Council and Advice to all Builders, &c. London, 1663.

JOHN WEBB, a ſcholar of Inigo Jones, built in Great Queen Street.

FRANCIS CARTER, an Architect, chief clerk of works under Inigo Jones.

FRANCIS FANELLI, a Sculptor, a Florentine, publiſhed two books Architectural, of Fountains, Vaſes, &c. about 1661.

Captain WILLIAM WIND, a diſciple of Gerbier, 1663 to 1695.

MARSH, Architect, built Nottingham Caſtle, &c.

Doctor MORECROFT, an Architect, (according to Salmon) died in 1667, was Architect at the manor houſe of Fitzwalters.

WILLIAM TALMAN, Architect, built Thoreſby, Chatſworth, &c. 1671.

Monſieur POUGET, a French Architect, built Montagu-houſe, 1678.

Sir WILLIAM WILSON rebuilt the ſteeple of Warwick Church.

Sir CHRISTOPHER WREN built the nobleſt temple, the largeſt palace, and moſt ſumptuous hoſpital, in Great Britain; he reſtored London, and recorded its fall; viz. St. Paul's Church, Greenwich Hoſpital, alſo many pariſh churches, the Monument, &c. and rebuilt Hampton Court; born at London, 1632, died 1723.

Sir JOHN VANBURGH built Blenheim, Caſtle-Howard, King's Weſton, Eaſton-Neſton, the Opera Houſe, &c. &c. died 1726. Dr. Evans wrote the following epitaph on Sir John:

" Lie heavy on him, Earth, for he
" Laid many a heavy load on thee."

ROBERTI, an Artichect.

EDWARD PIERCE, Statuary and Architect, died 1698, was an aſſiſtant to Sir Chriſtoper Wren.

ARCHER and WAKEFIELD, two Architects, followers and admirers of Sir John Vanbrugh's ſtyle.

NICHOLAS HAWKSMOOR, a diſciple of Sir Chriſtopher Wren, built St. Mary Woolnorth's Church, Chriſt Church, Spitalfields, St. George's, Middleſex, St. Ann's, Limehouſe, and St. George's, Bloomſbury, &c. died 1736.

EDWARD SHEPHERD built the north ſide of Groſvenor Square, and major part of North and South Audley Streets, &c. about 1729.

COLIN CAMPBELL built Wanſted Houſe, the Rolls, Mereworth in Kent, and publiſhed the three firſt volumes of Vitruvius Britannicus, died 1734.

WILLIAM THORNTON invented a framing of timber, and ſet upright Beverly Minſter, which over-hung four feet. Two prints thereof publiſhed in 1739.

JAMES GIBBS, Architect, ſtudied in Italy, built St. Martin's Church, St. Mary-le-Strand, New Church at Derby, the New Building at King's College, Cambridge, the Ratcliffe Library, St. Bartholomew's Hoſpital, &c. died 1754.

JOHN JAMES, of Greenwich, built Sir Gregory Page's, Blackheath, St. George's Church, Hanover Square, St. Luke's, Middleſex, &c.

GIACOMO LEONI, a Venetian, built the Duke of Queenſborough's houſe, Burlington Gardens; deſigned a large houſe for Mr. Scawen, at Carſhalton, in Surrey; publiſhed an edition of Palladio in 1742; died 1746.

JOHN NICHOLAS SERVANDONI gave the deſign for the Fireworks for the Peace, 1748.

THOMAS RIPLEY built the Admiralty, Woolterton, and Houghton, from Campbell's deſign.

BATTY LANGLEY pirated and publiſhed various books on Architecture, and is ſaid to be the inventor of artificial ſtone.

HERBERT, Earl of Pembroke, of Wilton, excelled in Architecture, and was a great patron of the art.

BOYLE, Earl of Burlington, was a great artiſt himſelf, and Architecture ſhone with luſtre under his auſpices; he was a great admirer of Palladio and Inigo Jones's works; he deſigned Chiſwick Houſe; the New Front and Colonnade at Burlington Houſe; the Dormitory, at Weſtminſter School; the Aſſembly Room, at York; Lord Harrington's, at Peterſham; Duke of Richmond's, at Whitehall; and General Wade's, in Cork Street; aſſiſted Mr. Kent in the publication of the deſigns for Whitehall, by Inigo Jones, and was a great friend and patron of that artiſt.

WILLIAM KENT ſtudied at Rome, where the Earl of Burlington met with him, and took him under his protection; it appears he was more employed as a painter than an Architect; he deſigned the King's Bench, in Weſtminſter Hall; Mr. Pelham's, at Eſher, in the Gothic ſtyle; he deſigned Holkham, in Norfolk, which alone is enough to eſtabliſh his abilities as an Architect, without further proofs. He died in 1748.

BRETTINGHAM built Holkham from Kent's deſign.

ISAAC WARE, Architect, built the Horſe Guards, &c. and publiſhed a complete Syſtem of Architecture, 2 vols. folio.

CHARLES LABELYE, a Swiſs, built Weſtminſter Bridge, died 1762.

HENRY FLITCROFT built St. Giles's Church, St. Olave's, Southwark, &c.

GEORGE DANCE built St. Leonard's, Shoreditch; the Manſion Houſe, London, &c,

ROGER MORRIS, Architect.

ROBERT MORRIS, his nephew, publiſhed ſeveral books of Deſigns on Architecture, and read ingenious lectures, founded upon harmonic and arithmetical proportions, 1730 to 1734.

SANDERSON MILLER, Eſq; of Radway, an Architect in the Gothic ſtyle.

WILLIAM JONES, (called Symmetry Jones) built the India Houſe, &c.

Vardy, Architect, built Lord Spencer's Houſe facing the Green Park, &c.

Stephen Wright, Surveyor of the Board of Works.

Edward Stephens, a diſciple of Sir William Chambers, died in purſuit of his ſtudies at Rome.

Wood, of Bath, built the Creſcent, &c.

Cooley, in Ireland, built the Exchange at Dublin; the ſucceſsful Candidate from England, 1769.

John Gwyn built ſeveral Bridges, &c. and publiſhed London and Weſtminſter improved.

James Payne built many capital Houſes in different parts of England; Richmond Bridge; Chertſey Bridge; altered Walton Bridge; built the New Stone Bridge at Kew, &c. and publiſhed his Works, 2 vols. folio.

Sir Robert Taylor built Maidenhead Bridge; the Six Clerks Office, Chancery Lane; the Stone Buildings, Lincoln's Inn; the additions to the Bank of England, &c. died 1788.

We do not preſume to recite a faithful record of all the deceaſed Artiſts who have deſerved a place with thoſe already mentioned; but have given them from the beſt authorities we could collect; we therefore preſume the public will excuſe auy little omiſſion they may diſcover, as we have aimed to be as faithful as poſſible in this brief account of them.

ARCHITECTURE is of three different claſſes; viz. Civil, Military, and Naval.

Civil Architecture, is the art of contriving, or deſigning and executing, commodious buildings for the uſes of civil life; as Houſes, Churches, Halls, Bridges, Palaces, Colleges, Temples, Porticos, &c.

Military Architecture, to deſign and erect Fortifications, Ramparts, &c. for places of defence, as offence againſt an enemy; the Military Architect is called an Engineer. See Engineer.

Naval Architecture, is the art of laying down, and building all kinds of veſſels to float on the water, and docks for the purpoſes thereof, and other aquatic works belonging thereto; and is called a Ship Builder. See Ship Builder.

Therefore Civil Architecture, by way of pre-eminence, is called Architecture.

The origin of Architecture cannot, with any degree of certainty, be traced; and it is unfortunate our earlieſt anceſtors were not aware of the curioſity which would inſpire their deſcendants, of knowing minutely the period of their invention; when they affixed branches of trees in the earth, uniting them at the top, and covering them with ſmaller boughs, turf, clay, graſs, &c. and making holes or caves in the earth and rocks, to keep them from the inclemency of the weather; the good people were not apprized they were then diſcovering Architecture, and that it might be learnedly agitated ſome thouſand years afterwards, who was the inventor of that moſt noble ſcience.

Neceſſity is certainly the parent of moſt of the common arts; therefore, upon the common ground Sir William Chambers, in his excellent Treatiſe on Civil Architecture, takes up the idea of primitive Huts, we may venture to proceed, and which is, indeed, corroborated by various diſcoveries made by our modern voyagers to the South Seas, and countries in their original ſtate of barbariſm.

The Huts of Terra del Fuego, Oonalaſhka, Kamſchatka, Atooi, the Pelew Iſlands, &c. (ſome of which are in Plate VII. of this Syſtem) are evident proofs of the conjecture; with this difference, they don't ſeem yet to have arrived at Sir William's refinement of the ſecond and third claſſes, from which, it is ſuppoſed gave birth to the orders; though, indeed, the inſide of the Kamſchatka habitation, and the places of public diverſion of Ulietea, Otaheite, and Poulaho, ſeem to indicate columns. See Plate VII. of this Syſtem.

It is hardly to be doubted but ſome degree of regularity, convenience, and even proportion, in the diſpoſition of the ſeveral parts of original building, were known, and practiſed before the orders were inſtituted; and it is to be lamented, that either through ignorance or obſtinacy, the inhabitants of the northern parts of this enlightened iſland are yet ſtrangers to even that comfort; and, as a proof thereof, truſt that the following detail will not be deemed a digreſſion.

The Bothag or Botheys, ſo called, being the habitations of the farmers in the highlands of Scotland, are inform of a parallelogram, and built with turf; poſts are worked therein, in a very rough manner, inclining to a point, to form a roof; boughs are laid thereon, and covered with turf lapping over each other, ſomething in the manner of tiles or ſlates; the turf vegetates in wet weather, and the whole building looks like a green hill; the fire-place is ſurrounded with ſtones of a ſufficient height to ſecure the fire from doing damage, and the ſmoak circulates about the room till it eſcapes out at the door, through the roof, or out of a very ſmall hole cut through the turf for a window (which is without glaſs); the floor is of the earth, or clay well trod; and the partitions which divide the bed places, are made of rough ſlabs, nailed up with their uneven edges, without regard to privacy, or common decency; a boarded platform is raiſed above the ground for a bed-place; thereon is ſome ſtraw, in a kind of ſack, on which they repoſe, with very little covering but their plaid; the gentleman by whom I am favoured with this account, was under the neceſſity of reſiding in this Bothag about five months laſt ſummer; who alſo favours me with the drawing thereof, and with the neighbouring Bothags, making together a village, as repreſented in Plate VII. Syſtem of Architecture; he alſo obſerved, their principal food was potatoes and oat cake, and that they never had meat, unleſs ſome accident happened to their caſtle; and alſo declared, no part of the family ever waſhed or cleaned themſelves while he had his reſidence with them; the inſide of the building, and every thing therein, appeared of a black bronze colour; in theſe Bothags the Highland farmers ſeem to live happy enough among themſelves; but are not at all fond of, or accommodating to, ſtrangers. This family was of ſome repute and property in that part of the country. Its remoteneſs muſt ſurely have never allowed its inhabitants the taſte of the common comforts of life; for it is evident no city in Europe is ſuperior, for taſte and elegance, to its capital, allowing for the magnitude.

Having conſidered the firſt, or primitive idea of dwellings, I now to proceed to thoſe of Divine Worſhip.

The ſuperſtition of conſecrating groves and woods to particular deities, was a practice very uſual with the ancients; for, not to ſpeak of thoſe mentioned in Holy Scripture, Pliny tells us, that trees, in old time, ſerved for the Temples of Gods; Tacitus reports this cuſtom of the old Germans; Q. Curtius of the Indians; and almoſt all writers of the Druids. The Romans, too, were great admirers of this worſhip, and therefore had their Luci, or conſecrated groves, in moſt parts of the city.

The moſt probable reaſon given for this practice is, that thoſe dark and lonely ſituations created that fear and awe which ſtruck them with a more proper degree of divine reverence; therefore, thoſe places, being appointed for their worſhip, gives us the preſumption of Primitive Churches; which idea, with an eye to its origin, the Gothic Architecture ſprung.

The bodies of trees in rows, forming an avenue, reſemble the pillars; the ſhoots and ſuckers adhering thereto, the ſmaller pillars; the joints, from whence the buds ſhoot, the aſtragals or mouldings; the boughs and ramifications, the groins and vaulted arches; and their interſecting at the top, and ſome returning downward, the apex thereof, and the pendant ornaments; as in the Chapel of Henry the Seventh, at Weſtminſter Abbey, ſo far we may venture on ideal reaſoning on the conſtruction of Gothic Architecture. Its firſt practice is not eaſy to be traced; indeed we read of its being introducted in Rome when that empire was overrun by the Goths, after the reign of Alexander Severus, but know not from whence to date its origin.

Building, in its minority, was undoubtedly not only plain, but irregular; and nothing more conſidered than bare neceſſity urged; when, by degrees, mankind inſenſibly improved in the art, and invented methods to make their habitations comfortable and laſting; and therefore, when ſociety began to encreaſe in numbers and wealth, by traffic and commerce, their ideas made gradual advances toward rule, order, and elegance; and at length diſcovered a ſtyle of building which ſucceeding ages have greatly admired and venerated.

When arts and learning became famous in Egypt, Perſia, Aſſyria, &c. with them Architecture flouriſhed; for we find works amazingly elaborate, mentioned among the great deſigners cotemporary with Noah; in the year of the world 2038, the Walls of Babylon are reported to have been built by Semiramis, very magnificent, and eſteemed one of the Seven Wonders of the World: the Pyramids or Sepulchres of Egypt, in the deſart of Libya, was another of them; the ground whereon the largeſt ſtands containing eleven acres and a quarter, and near five hundred feet high; the baſe of which may be readily compared by the incloſure of Lincoln's-Inn-Fields, which Inigo Jones ſet out, by the reported dimenſions of the largeſt of the Egyptian Pyramids; the Great Wall of China, fifteen hundred miles long, and thirty feet high, and broad enough for eight perſons to ride abreaſt upon.

The Sepulchre of Porſena, king of Hetruria, deſcribed by Pliny, out of Varro, is of an extraordinary nature; this king was buried without the city Cluſium, in which place was erected a monument of ſquare ſtone; each ſide of it three hundred feet broad, and fifty feet high; within the ſquare baſis there is an inextricable labyrinth, whither, whoſo ventures without a clue, can find no paſſage out; upon this ſquare ſtands five Pyramids, four in the angles, and one in the middle; in the bottom they are ſeventy-five feet broad and one hundred and fifty feet high; they are pointed in ſuch a manner, that, at the top, there is one braſs circle and covering for them all; from which there hang bells, faſtened by chains; thoſe being moved by the wind, give a ſound afar off. Upon this circle there are four other Pyramids, each of them an hundred feet high; above which, upon one plane, there are five Pyramids, the altitude of which Varro was aſhamed to add. The Etruſcan fables report, that it was as much as that of the whole work; the end of which, the Artificer's fame ſeems more recorded than king Porſena's.

The Tower of Babel is another remarkable inſtance of the early knowledge of building. The two famous pillars, one of brick, the other of ſtone, erected ſoon after the flood by the ſons of Noah, on which were recorded the remarkable paſſages, from the Creation down to the Flood. The Palace near Andera, in Upper Egypt; the ruins of Perſepolis; the amazing Labyrinths; extenſive Lakes; gigantic Obeliſks; and wonderful Staircaſes, &c. are evident teſtimonies of their ſkill, perſeverance, and progreſs in Mathematical and Architectural Arts.

Moſt of our writers, on theſe ſubjects, ſeem to agree, that Arches were not known or practiſed in any of theſe ſtructures, as the cielings and roofs were flat, and ſupported by clumſy pillars; and that it is evident their buildings were more remarkable for their magnitude and vaſtneſs, than for their elegance and convenience, notwithſtanding Architecture arrived at great perfection among the Egyptians. To Egypt the firſt Grecian Architects were uſed to travel, as our modern artiſts do to Rome, for Improvement.

The arts were firſt conveyed into Greece by Cadmus (Grandſon to Agenor, King of Tyre, 562 years after the Walls of Babylon were built) from the Phœnicians, and built Thebes, called ſo from the famous Thebes in Egypt: and we find, that about 300 years after the foundation of Rome was laid, that Phidias, an Athenian, built a Temple of the Doric Order, whoſe height was ſixty-eight feet to the roof; and, it is ſaid, the Grecians never made uſe of but one order in the height of their buildings.

Greece was furniſhed with many noble monuments of building, which were brought to Rome by Marcellus; viz. The Temple of Jupiter Olympus, the Temple of Cizenis, which Pliny reports was ſo rich and curiouſly wrought, that in all the joints of the ſtone, threads of gold were inlaid to ſeparate them; the Temple of Trallius; of Diana; of Pallas; of Minerva at Athens; of Apollo, &c. all ſo teſtify the nobleneſs, uſe, and beauty of Architecture, before it was brought to Rome, that the forementioned author relates, that Cecrops, the firſt king of Athens, 200 years before the deſtruction of Troy, founded a ſchool for the inſtruction and encouragement of Architects; and to them the invention of three of the regular Orders of Architecture are attributed; viz. The Doric, Ionic, and Corinthian; if they collected any ideas of beauty or proportion from the Egyptians, they cultivated, improved and brought them to perfection; as the orders alluded to, are yet unexampled ſtandards of taſte and beautiful proportion, as appears by the remaining antiquities of that country in various publications.

Greece happily perfected the art; but ambitious Rome ſtole Architecture from her, and laid deſolate its glory; the Emperors pulled down her ſtately Edifices and Temples, and tranſported them to Rome; there confined the art and materials to raiſe and immortalize themſelves and poſterity.

Rome, poſſeſſed of the ineſtimable prize, and at the ſame time ſo extenſive and opulent, ſelected together the greateſt artiſts of thoſe times; and, by their aſſiduity and unwearied purſuits, traced the paths and footſteps of the Grecians, both in learning, arts, and government.

Athens furniſhed them with exemplary rules; and, being naturally aſpiring, they ſhone forth in the luſtre and perfection of Architecture, in the various noble Structures and Temples which they erected to the honour of their emperors, and the victorious conqueſts they made, particularly in their Triumphal Arches, Baſilicæs, Aquæducts, and Baths, which were amazingly rich and elegant; Circi or Circuſes; that of Maximus is ſaid to have been large enough to contain two hundred and ſixty thouſand ſpectators in their proper places; Caracalla cauſed divers parts of it to be ornamented with paint and gilding; and Heliogabalus ordered its floor, on ſome occaſions, to be ſtrewed with gold and ſilver duſt. Columns and Obiliſks; their Domi or capital Houſes; Forums; Gates; Palaces; Porticos; Temples in great numbers; Theatres and Amphitheatres; of which the Coliſeum and Theatre of Marcellus, built by Auguſtus, are beautiful remains of Roman antiquity; alſo Mauſoleums, Tombs and Sepulchres; Luci or Groves, &c. &c.

Rome, in its flouriſhing ſtate, under the Conſuls and Emperors, who were ſo much given to building, at one time is ſaid to have in employ upwards of four hundred Architects.

Pompey the Great is reported by Tacitus to have built the firſt Amphitheatre at Rome; and Marcellus, happy in victory, together with a fine genius, brought from Greece that moſt beautiful and regular piece of Architecture, called after his name. The magnificence of the Romans in their public buildings, many of which are yet to be ſeen, and others traced by their veſtiges, and which are frequently viſited by admirers of the art, and our modern Architects, who are purſuing the ſtudy, are evident proofs the Art of Architecture was in their full poſſeſſion for about two centuries, when it declined rapidly as the empire was overturned, after the battle of Actium, when the Goths prevailed, who naturally introduced their own ſtyle of building, which, being grafted to the Roman, produce a miſerable effect. We ſee many inſtances of that clumſy barbarity in various publications, particularly in the Views of Venice.

Apprehending that authors diſagreeing in their accounts of the Meaſures of Antiquity, ariſes either from the inſtrument they are taken with, or that they truſted to information or tranſlations; not conſidering properly the meaſures of cuſtomary feet in different countries, or I ſhould have more particularly explained ſome of the beforementioned amazing buildings. But finding their dimenſions variouſly expreſſed by different authors, I could not aſcertain with that degree of certainty I wiſh; as the following Table will explain.

“ The firſt mention of a Chriſtian Church in this iſland, is ſaid to have been built by Joſeph, of Arimethea, and his company in the iſle of Avalon, ſometimes called Iris Witrin, and ſince Glaſtenbury. This Joſeph, as is ſaid by a wonderful Providence, being arrived in Britain with ten or twelve aſſociates, obtained leave from Arvirageas, their king, to ſettle with ſome accommodations at Glaſtenbury, in Somerſetſhire, where he and his companions erected a ſmall Church, and, as it is alſo ſaid, by direction of the arch-angel Gabriel; this he incloſed with a Church-yard, and dedicated to the Virgin Mary; and for the materials and dimenſions of this Church they are thus deſcribed, viz. It had in length ſixty feet, in breadth twenty-ſix feet, and made of wooden rods, interwoven or watled; the Icon, whereof we have here thought fit, ſuitable to its traditional dimenſions, to exhibit unto view, ſee Plate VI. Syſtem of Architecture. This Church when finiſhed, was their Church or Oratory, wherein to pray, watch, faſt, and preach; and in or near to which Joſeph himſelf was afterwards buried; and ſome have ſince pretended to have recovered his Epitaph, thus, *Ad Britones veni poſt quam Chriſtum ſepe livi; docui, requieve.* Other particulars of tradition: there are alſo ſeveral paſſages at the founding of this Church; of relicks there repoſited, endowment, and other matters; of all which, in all the circumſtances, if any one ſhall ſuſpend a full belief, I ſhall not preſently therefore eſteem him an infidel; ſeeing much of this nature hath ſufficiently been detected to be but the product of Monkiſh ignorance, or vanity accommodated to the humour and perſuaſion of thoſe times the writers lived in: as there is ſcarce any Saint in all the Kalendar, whoſe hiſtory would not be much ſuſpected or prejudiced, if the additions of the middle or darker times ſhould be urged to the undermining and diſparagement of the whole narration. Yet, for the main, that ſome Cell, Chapel, Church, Oratory, or convenient receptacle was there erected, dedicated, and uſed for divine ſervice, there are many reaſons and circumſtances which may induce an innocent perſuaſion. And that firſt, in regard of the general conſent of writers, ſince that time; then by the obſervation of the frame and tenor of the Norman characters of Glaſtenbury, referring to a ſucceſſion of many ancient characters beſtowed on that Church by ſeveral Saxon kings, whoſe characters alſo relate to the Britiſh grants before, and all pointing at the being and actions of Joſeph there. And upon this conſideration it was, that this place was much honoured by our devout anceſtors by the appellations of, *The firſt land of God. The firſt land of Saints in England. The beginning and fountain of all Religion in England. The Tomb of Saints. The Mother of Saints. The Church founded and built by the Lord's Diſciples, &c.*

What further was the ſtate and ſucceſſion of this Primitive Church, is recorded thus: That where the little old Cell, or Chapel, built by the forenamed Joſeph, was decayed by time; Demi, a Welch or Britiſh biſhop, built a new one in the ſame place; and this alſo in time falling to decay, twelve men came out of North Britain and put it in good repair; and laſtly, king Ina, donor of the Peter-pence, pulled down the old one, and erected a fair and ſtately Church to the honour of Chriſt and St. Peter, and St. Paul, filleted under the higheſt coping, with heroic verſes in Latin, celebrating the memory of the Founder, and the Saints to whom it was dedicated; which verſes have been borrowed and applied, with ſome variation, by Venatius Fortunatus, in praiſe of ſome ſtately Churches in France; but afterwards, this was by the famous Dunſtan, converted to a Monaſtery of Benedictine Monks, himſelf being ſometimes Abbot there; in which quality it continued till the time of Henry the Eighth, when it participated of the great downfall of Abbies, whilſt, by its late ruins, it was not hard to trace its former dimenſions and magnificence.

In Britain, before the Roman invaſion, the natives appear to have had no better lodgings than thickets, dens, and caves. Some of theſe caves, which were their winter-habitations, and places of retreat in time of war, were formed and rendered ſecure and warm by art, like thoſe of the ancient Germans, which are thus deſcribed by Tacitus: “ They are uſed to dig deep caves in the ground and cover them with earth, where they lay up their proviſions,

ſions, and dwell in winter for the ſake of warmth. Into thoſe they retire alſo from their enemies, who plunder the open country, but cannot diſcover theſe ſubterranean receſſes." Some of the ſubterraneous, or earth-houſes, as they are called, are ſtill remaining in the weſtern iſles of Scotland and in Cornwall. The ſummer habitations of the moſt ancient Britons were very ſlight; and, like thoſe of the Finnians, conſiſted only of a few ſtakes driven into the ground, interwoven with wattles, and covered over with the boughs of trees.

When Julius Cæſar invaded Britain, the inhabitants of Cantium, Kent, and of ſome other parts in the ſouth, had learned to build houſes a little more ſubſtantial and convenient. "The country, ſays Cæſar, abounds in houſes, which very much reſemble thoſe of Gaul." The firſt ſtep towards this improvement ſeems to have been that of daubing the wattled walls of their houſes with clay, to fill up the chinks and make them warmer. "The Germans uſed for this purpoſe a kind of pure reſplendent earth of different colours, which had an appearance of painting at a diſtance;" but the Gauls and Britains choſe rather to whitewaſh the clay after it was dry with chalk. Inſtead of the boughs of trees, they thatched theſe houſes with ſtraw, as a much better ſecurity againſt the weather. They next proceeded to form the walls of large beams of wood, inſtead of ſtakes and wattles. This ſeems to have been the mode of building in Britain, when it was firſt invaded by the Romans. "The Britons, ſays Diodorus Siculus, who was cotemporary with Cæſar, dwell in wretched cottages, which are conſtructed of wood, covered with ſtraw." Theſe wooden houſes of the ancient Gauls and Britons were not ſquare but circular, with high tapering roofs, at the top or center of which was an aperture for the admiſſion of light and emiſſion of ſmoke. Thoſe of Gaul are thus deſcribed by Strabo: "They build their houſes of wood, in the form of a circle, with lofty tapering roofs." The foundations of ſome of the moſt magnificent of theſe circular houſes were of ſtone, of which there are ſome veſtiges ſtill remaining in Angleſey and other places. It was probably in imitation of theſe wooden houſes, that the moſt ancient ſtone edifices, of which there are ſtill ſome remains in the weſtern iſlands of Scotland, were built circular, and have a large aperture at the top.

When the Britons were invaded by the Romans, they had nothing among them anſwering to our ideas of a city or town, conſiſting of a great number of contiguous houſes, diſpoſed into regular ſtreets, lanes, and courts. Their dwellings, like thoſe of the ancient Germans, were ſcattered about the country, and generally ſituated on the brink of ſome rivulet for the ſake of water, and on the ſkirt of ſome wood or foreſt for the conveniency of hunting and paſture for their cattle. As theſe inviting circumſtances were more conſpicuous in ſome parts of the country than others, the princes and chiefs made choice of theſe places for their reſidence; and a number of their friends and followers, for various reaſons, built their houſes as near to them as they could with conveniency. This naturally produced an ancient Britiſh town, which is deſcribed by Cæſar and Strabo in the following manner: "From the Caſſi he learnt that the town of Caſſivelaun was at no great diſtance; a place defended by woods and marſhes, in which very great numbers of men and cattle were collected. For what the Britons call a town, is a tract of woody country, ſurrounded by a mound and ditch, for the ſecurity of themſelves and their cattle againſt the incurſions of their enemies." "The foreſts of the Britons are their cities: for when they have incloſed a very large circuit with felled trees, they build within it houſes for themſelves and hovels for their cattle. Theſe buildings are very ſlight, and not deſigned for long duration." The palaces of the Britiſh princes were probably built of the ſame materials, and on the ſame plan, with the houſes of their ſubjects, and differed from them only in ſolidity and magnitude.

Though the communication between this iſland and the continent was more free and open after the firſt Roman invaſion than it had been before, and ſome of the Britiſh princes and chieftains even viſited Rome, then in its greateſt glory; it doth not appear that the people of Britain made any conſiderable improvements in their manner of building for at leaſt a hundred years after that invaſion. For when the renowned Caractacus was carried priſoner to Rome, A. D. 52, and obſerved the beauty and magnificence of the buildings in that proud metropolis of the world, he is ſaid to have expreſſed great ſurpriſe, "That the Romans, who had ſuch magnificent palaces of their own, ſhould envy the wretched cabbins of the Britons."

It muſt appear very ſurpriſing that the ancient Britons, when they were ſo ignorant of architecture, were capable of erecting, if indeed it was erected by them, ſo ſtupendous a fabric as that of Stonehenge on Saliſbury plain: a fabric which hath been the admiration of all ſucceeding ages, and hath outlaſted all the ſolid and noble ſtructures which were erected by the Romans in this iſland.

Of another very extraordinary ſpecies of building ſeveral remains are found in the Highlands of Scotland. They conſiſt of ruins; the walls of which, inſtead of being cemented with lime or ſome other ſimilar ſubſtance, or of being raiſed with dry ſtones, as was the method before cement came into uſe, are deſcribed as having been vitrefied, or the ſtones run and compacted together by the force of fire. Concerning the origin, uſe, &c. of theſe buildings, different opinions have been formed; and even the reality of them as works of contrivance has been called in queſtion.

But for whatever purpoſes, or by whatever means, the above and other ſimilar ſtructures of a peculiar nature were erected, we have ſufficient evidence that the people of Britain, before they were ſubdued and inſtructed by the Romans, had but a rude knowledge of architecture, and were very meanly lodged. As ſoon, however, as the Romans began to form ſettlements and plant colonies in this iſland, a ſudden and ſurpriſing change enſued in the ſtate of architecture. For that wonderful people were as induſtrious as they were brave, and made haſte to adorn every country that they conquered. The firſt Roman colony was planted at Camelodunum, A. D. 50; and when it was deſtroyed by the Britons in their great revolt under Boadicia, only eleven years after, it appears to have been a large and well built town, adorned with ſtatues, temples, theatres, and other public edifices.

The Romans not only built a prodigious number of ſolid, convenient, and magnificent ſtructures for their own accommodation, but they exhorted, encouraged, and inſtructed the Britons to imitate their example. This was one of the arts which Agricola, the moſt excellent of the Roman governors, employed to civilize the Britons, and reconcile them to the Roman government. "The following winter, ſays Tacitus, was ſpent by Agricola in very ſalutary meaſures. That the Britons, who led a roaming and unſettled life, and were eaſily inſtigated to war, might contract a love to peace and tranquillity, by being accuſtomed to a more pleaſant way of living, he exhorted and aſſiſted them to build houſes, temples, courts, and market-places. By praiſing the diligent and reproaching the indolent, he excited ſo great an emulation among the Britons, that after they had erected all thoſe neceſſary edifices in their towns, they proceeded to build others merely for ornament and pleaſure, as porticoes, galleries, baths, banqueting-houſes, &c." From this time, which was A. D. 80, to the middle of the fourth century, architecture, and all the arts immediately connected with it greatly flouriſhed in this iſland; and the ſame taſte for erecting ſolid, convenient, and beautiful buildings, which had long prevailed in Italy, was introduced into Britain. Every Roman colony and free city, of which there was a great number in this country, was a little Rome, encompaſſed with ſtrong walls, adorned with temples, palaces, courts, balls, baſilicas, baths, markets, aqueducts, and many other fine buildings, both for uſe and ornament. The country every where abounded with well-built villages, towns, forts, and ſtations; and the whole was defended by that high and ſtrong wall, with its many towers and caſtles, which reached from the mouth of the river Tine on the eaſt to the Solway Firth on the weſt. This ſpirit of building, which was introduced and encouraged by the Romans, ſo much improved the taſte and increaſed the number of the Britiſh builders, that in the third century this iſland was famous for the great number and excellence of its architects and artificers. When the emperor Conſtantius, father of Conſtantine the Great, rebuilt the city of Autun in Gaul, A. D. 296, he was chiefly furniſhed with workmen from Britain, "which, ſays Eumenius, very much abounded with the beſt artificers."

Not very long after this period, architecture and all the arts connected with it began to decline very ſenſibly in Britain, and in all the provinces of the weſtern empire. This was partly owing to the building of Conſtantinople, which drew many of the moſt famous architects and other artificers into the eaſt, and partly to the irruptions and depredations of the barbarous nations.

The final departure of the Romans was followed by the almoſt total deſtruction of architecture in this iſland. For the unhappy and unwarlike people whom they left behind, having neither ſkill nor courage to defend the numerous towns, forts, and cities which they poſſeſſed, they were ſeized by their ferocious invaders, who firſt plundered and then deſtroyed them. By this means, the many noble ſtructures with which Provincial Britain had been adorned by the art and induſtry of the Romans, were ruined or defaced in a very little time; and the unfortunate Britons were quite incapable of repairing them, or of building others in their room. That long ſucceſſion of miſeries in which they were involved by the Scots, Picts, and Saxons, deprived them of the many uſeful arts which they had learned from their former maſters, and lodged them once more in foreſts, dens, and caves, like their ſavage anceſtors.

The moſt wanton and extenſive devaſtations were thoſe committed by the Anglo-Saxons; among whom it ſeems to have been a maxim to deſtroy all the towns and caſtles which they took from their enemies, inſtead of preſerving them for their own uſe.

About the time of the Saxons firſt appearing on this iſland, in the year of Chriſt 420, Germanus, and Lupus, two orthodox French biſhops, came over to ſuppreſs the errors that Pelagius had broached in Britain: by the conduct and prudence of that pious man, a great victory was obtained by the Britons againſt the Saxons and Picts, whereupon ſeveral Churches were built to the memory of Germanus, one at St. Germains, in Cornwall; ſometime a biſhop's ſee, but after tranſlated to Exeter; and near to old Verulam, a Chapel was erected to the memory of St. Germain; William the Conqueror alſo built an Abby at Selby in Yorkſhire, in memory of this St. Germain, who had confuted the Pelagian hereſy. The like honour having been alſo done to the memory of St. Helena, mother of Conſtantine, by inſcribing Churches with her name, teſtified by Hellenſtow, in Berkſhire; St. Helen's, Bedford; St. Helen's, London, &c.

It cannot be ſuppoſed, that a people who wantonly demoliſhed ſo many beautiful and uſeful ſtructures had any taſte for the arts by which they had been erected. The truth is, that the Anglo-Saxons at their arrival in this iſland were almoſt totally ignorant of theſe arts; and, like all the other nations of Germany, had been accuſtomed to live in wretched hovels, built of wood or earth, and covered with ſtraw or the branches of trees: nor did they much improve in the knowledge of architecture for 200 years after their arrival. During that period, maſonry was quite unknown and unpractiſed in this iſland; and the walls even of cathedral churches were built of wood. "There was a time, ſays Venerable Bede, when there was not a ſtone church in all the land; but the cuſtom was to build them all of wood. Finan, the ſecond biſhop of Lindiſfarne, or Holy iſland, built a church in that iſland A. D. 652, for a cathedral, which yet was not of ſtone, but of wood, and covered with reeds; and ſo it continued till Eadbert, the ſucceſſor of St. Cuthbert, and ſeventh biſhop of Lindiſfarne, took away the reeds, and covered it all over, both roof and walls, with ſheets of lead." The firſt cathedral of York was built of the ſame materials; and a church of ſtone was eſteemed a kind of prodigy in thoſe times that merited a place in hiſtory. "Paulinus, the firſt biſhop of York, built a church of ſtone in the city of Lincoln, whoſe walls, ſays Bede, are ſtill ſtanding, though the roof is fallen down; and ſome healing miracles are wrought in it every year, for the benefit of thoſe who have the faith to ſeek them."

"About the year of Chriſt 659, Wulphere, king of Mercia, being a Pagan, underſtanding that two of his ſons, under pretence of hunting, often reſorted to St. Chad, the famous biſhop of Lichfield, to be by him inſtructed in Chriſtianity, to which they were inclined; he, once miſſing his ſons, haſted, in great rage, to St. Chad, with whom in a private oratory he found his ſons, and there with his own hand he ſlew them both; in memory whereof their mother Erminhild afterwards cauſed a Church in that place to be erected; the foundation and ſtructure whereof being of ſuch a quantity and quality of ſtone as was unuſual at thoſe times; for the rariety thereof it acquired the name of Stone, which is continued to the market-town thereof to this day." Camb. Brit. fol. 583.

There does not ſeem to have been ſo much as one church of ſtone, nor any artiſts who could build one, in all Scotland, at the beginning of the eighth century. For Naitan, king of the Picts, in his famous letter to Ceolfred, abbot of Weremouth, A. D. 710, earneſtly intreats him to ſend him ſome maſons to build a church of ſtone in his kingdom, in imitation of the Romans; which he promiſes to dedicate to the honour of the apoſtle Peter, to whom the abbey of Weremouth was dedicated: and we are told by Bede, who was then living in that abbey, that the reverend abbot Ceolfred granted this pious requeſt, and ſent maſons according to his deſire.

Maſonry was reſtored, and ſome other arts with it introduced into England, towards the end of the ſeventh century, by two clergymen, who were great travellers, and had often viſited Rome, where they had acquired ſome taſte for theſe arts. Theſe were, the famous Wilfrid, biſhop of York, and afterwards of Hexham, and Benedict Biſcop, founder of the abbey of Weremouth.

Wilfrid, who was one of the moſt ingenious, active, and magnificent prelates of the ſeventh century, was a great builder, and erected ſeveral ſtructures at York, Rippon, and Hexham, which were the admiration of the age in which he flouriſhed.

The cathedral of Hexham, which was one of theſe ſtructures, is thus deſcribed by his biographer: "Having obtained a piece of ground at Hexham from Queen Etheldreda, he there founded a moſt magnificent church, which he dedicated to the bleſſed apoſtle St. Andrew.

As the plan of this ſacred ſtructure ſeems to have been inſpired by the Spirit of God, it would require a genius much ſuperior to mine to deſcribe it properly. How large and ſtrong were the ſubterraneous buildings, conſtructed of the fineſt poliſhed ſtones! How magnificent the ſuperſtructure, with its lofty roof, ſupported by many pillars; its long and high walls; its ſublime towers, and winding ſtairs! In one word, there is no church on this ſide of the Alps, ſo great and beautiful."

This admired edifice, of which ſome veſtiges are ſtill remaining, was built by maſons, and other artificers brought from Rome, by the munificence of its generous founder. Benedict Biſcop was the cotemporary and companion of Wilfrid in ſome of his journies, and had the ſame taſte for the arts. He made no fewer than ſix journies to Rome, chiefly with a view of collecting books, pictures, ſtatues, and other curioſities; and of perſuading artificers, of various kinds, to come from Italy and France, and ſettle in England. Having obtained a grant of a conſiderable eſtate from Egfrid, king of Northumberland, near the mouth of the river Were, he there founded a monaſtery, A. D. 674.

"About a year after the foundation of this monaſtery were laid, Benedict croſſed the ſea into France, where he collected a number of maſons, and brought them over with him, in order to build the church of his monaſtery of ſtone, after the Roman manner, of which he was a great admirer. His love to the apoſtle Peter, to whom he deſigned to dedicate his church, made him urge theſe workmen to labour ſo hard, that maſs was celebrated in it about a year after it was founded. When the work was far advanced, he ſent agents into France, to procure, if poſſible, ſome glaſs-makers, a kind of artificers quite unknown in England, and to bring them over to glaze the windows of his church and monaſtery. Theſe agents were ſucceſsful, and brought ſeveral glaſs-makers with them: who not only performed the work required by Benedict, but inſtructed the Engliſh in the art of making glaſs for windows, lamps, drinking veſſels, and other uſes."

But though theſe arts of building edifices of ſtone, with windows of glaſs, and other ornaments, were thus introduced by theſe two prelates in the latter part of the ſeventh century, they do not ſeem to have flouriſhed much for ſeveral centuries. It appears, from many incidental hints in our ancient hiſtorians, that ſtone buildings were ſtill very rare in the eighth and ninth ages; and, that when any ſuch buildings were erected, they were the objects of much admiration. When Alfred the Great, towards the end of the ninth century, formed the deſign of rebuilding his ruined cities, churches, and monaſteries, and of adorning his dominions with more magnificent ſtructures, he was obliged to bring many of his artificers from foreign countries. "Of theſe (as we are told by his friend and companion Aſſerius) he had an almoſt innumerable multitude, collected from different nations; many of them the moſt excellent in their ſeveral arts."

In the other parts of this iſland, Architecture was, as might naturally be imagined, in a ſtill leſs flouriſhing ſtate. It appears, indeed, to have been almoſt entirely loſt among the poſterity of the ancient Britons, after they retired to the mountains of Wales.

The chief palace of the kings of Wales, where the nobility and wiſe men aſſembled for making laws, was called White Palace, becauſe the walls of it were woven with white wands, which had the bark peeled off. By the laws of Wales, whoever burnt or deſtroyed the king's hall or palace, was obliged to pay one pound and eighty pence, beſides one hundred and twenty pence for each of the adjacent buildings, which were eight in number; viz. the dormitory, the kitchen, the chapel, the granary, the bake-houſe, the ſtore-houſe, the ſtable, and the dog-houſe. From hence it appears, that a royal reſidence in Wales, with all its offices, when theſe laws were made, was valued at five pounds and eighty pence of the money of that age, equal, in quantity of ſilver, to ſixteen pounds of our money, and, in efficacy, to one hundred and ſixty. This is certainly a ſufficient proof of the meanneſs of thoſe buildings, which were only of wood. Even the caſtles in Wales, at this period, that were built for the ſecurity of the country, appear to have been conſtructed of the ſame materials; for the laws required the kings vaſſals to come to the building of theſe caſtles, with no other tools but an axe.

The arts of building do not ſeem to have been much better underſtood by the Scots and Picts than by the ancient Britons, in the former part of this period. When Finant, the ſecond biſhop of Lindisfarne, built a church of wood in that iſland, A. D. 652, he is ſaid to have done it *more Scotorum*, after the manner of his countrymen the Scots; and it hath been already obſerved, that Naitan, king of the Picts, was obliged to bring maſons from Northumberland, when he reſolved to build a church of ſtone in his dominions, A. D. 710. After this laſt period, it is probable that the Picts, and perhaps the Scots, began to learn and practiſe the art of maſonry; becauſe there are ſtill ſome ſtone buildings of a very ſingular conſtruction, and great antiquity, to be ſeen in Scotland. Theſe buildings are all circular; though of two kinds, ſo different from each other, that they ſeem to be the works of different ages, and of different nations.

The largeſt of theſe ſtructures are in a very extraordinary taſte of Architecture; and are thus deſcribed by a modern antiquary, who viewed them with no little attention. "Having arrived at the barrack of Glenelg, I was conducted to the remains of thoſe ſtupendous fabrics, ſeated about two miles from thence, in a valley called Glenbeg, in which four of them anciently ſtood. Two of theſe are now almoſt quite demoliſhed; the third is half fallen down; the fourth is almoſt entire.

The firſt I met with lies towards the north ſide of the valley, and is called Caſtle Chalamine, or Malcom's Caſtle. It ſtands upon a conſiderable eminence, and affords us a fine proſpect of the Iſland of Sky, and a good part of the ſea-coaſt. The foundation of this only appears; as alſo of that other, on the eaſt end of the valley, called Caſtle Chonel. About a quarter of a mile further, upon the bank of a rivulet, which paſſes through the middle of the glen, ſtands the third fabric, called Caſtle Tellve. I found it compoſed of ſtones without cement; not laid in regular courſes, after the manner of elegant buildings, but rudely and without order. Thoſe toward the baſe were pretty large; but aſcending higher, they were thin and flat, ſome of them ſcarce exceeding the thickneſs of an ordinary brick. I was ſurpriſed to find no windows on the outſide, nor any manner of entrance into the fabric, except a hole towards the weſt, at the baſe ſo very low and narrow, that I was forced to creep in upon hands and knees, and found that it carried me down four or five ſteps below the ſurface of the ground. When I was got within, I was environed betwixt two walls, having a cavity or void ſpace which led me round the whole building. Oppoſite to the little entry, on the outſide, was a pretty large door, in the ſecond or inner wall, which let me into the area or inner court. When I was there, I perceived that one half of the building was fallen down, and thereby had an opportunity of ſeeing a complete ſection thereof. The two walls join together at the top, round about, and have formed a large void ſpace or area in the middle.

" But, to give a more compleat idea of theſe buildings, I ſhall deſcribe the fourth, called Caſtle Troddan, which is by far the moſt entire of any in that country, and from whence I had a very clear notion how theſe fabrics were originally contrived. On the outſide were no windows, nor were the materials of this caſtle any wiſe different from thoſe of the other already deſcribed, only the entry on the outſide was ſomewhat larger; but this might be occaſioned by the falling of the ſtones from above. The area of this makes a complete circle; and there are four doors in the inner wall, which face the four cardinal points of the compaſs. Theſe doors are each eight feet and an half high, and five feet wide, and lead from the area into the cavity between the two walls, which runs round the whole building. The perpendicular height of this fabric is exactly thirty-three feet; the thickneſs of both walls, including the cavity between, no more than twelve feet; and the cavity itſelf is hardly wide enough for two men to walk abreaſt; the external circumference is one hundred and ſeventy-eight feet. The whole height of the fabric is divided into four parts or ſtories, ſeparated from each other by thin floorings of flat ſtones, which knit the two walls together, and run quite round the building; and there have been winding ſtairs, of the ſame flat ſtones, aſcending betwixt wall and wall up to the top. The undermoſt partition is ſomewhat below the ſurface of the ground, and is the wideſt; the others grow narrower by degrees, till the walls cloſe at top. Over each door are nine ſquare windows, in a direct line above each other, for the admiſſion of light; and between every row of windows are three others in the uppermoſt ſtory, riſing above a cornice which projects out from the inner wall, and runs round the fabric."

From this deſcription of theſe ſingular edifices, it plainly appears, that they were deſigned both for lodging and defence; and, conſidering the ſtate of the times in which they were built, they were certainly very well contrived for anſwering both theſe purpoſes.

The ſtone edifices of the other kind, which were probably erected in this period, and of which ſome few are ſtill to be ſeen in Scotland, are not ſo large as the former, but more artificial. They are ſlender, lofty, circular towers, of cut ſtone, laid in regular rows, between forty and fifty feet in external circumference, and from ſeventy to one hundred feet high, with one door, ſome feet from the ground. They are exactly ſimilar to the round tower of Ardmore, and ſeveral others, in Ireland; and, therefore, were probably built about the ſame time, which was in the tenth century, and for the ſame purpoſes; which are believed by ſome to have been for the confinement of penitents, while they were performing penance.

On this account theſe towers are always found in the neighbourhood of churches, both in Scotland and Ireland; and are ſaid to have been uſed in this manner: " The penitents were placed in the uppermoſt ſtory of the tower (which commonly conſiſted of five or ſix ſtories); where, having made probation, or done penance, ſuch a limited time, according to the heinouſneſs of their crimes, they then were permitted to deſcend to the next floor, and ſo on by degrees, until they came to the door, which always faced the entrance of the church, where they ſtood to receive abſolution from the clergy, and the bleſſings of the people." A tedious proceſs, to which few penitents in the preſent age would willingly ſubmit.

Other writers are of opinion, that the deſign of theſe circular towers (one of which is ſtill remaining at Abernethy, and another at Brechin) was to be places from whence the people were called to public worſhip, by the ſound of a horn or trumpet, before the introduction of bells.

" Matt. Paris relates, that Offa, the great Saxon king, and firſt founder of the Abbey of St. Albans, built alſo the Church of St. Alban's, Wood-ſtreet, London, as a Chapel to his Palace, thereabouts ſituated; this was about the year 790."

It is ſaid of king Edgar, who reigned in the year 959, that he built above forty Monaſteries and Churches, and in particular the Church of St. Ives upon Uſk, the river of Huntingdon; and St. Giles's upon Grant, the river of Cambridge.

We read of Kenulphus, a king of Mercia, in the Saxon Heptarchy, who took Egbert, king of Kent, priſoner; but afterwards Kenulphus having built a Church at Winchcomb, upon the day of its dedication, in the preſence of ten noblemen, thirteen biſhops, and many other great perſonages, he brought the Royal priſoner Egbert into the New Built Church, and reſtored him to his liberty and kingdom again.

John Brompton relates, that at the building of St. Peter's Church in Hereford, WALTER DE LACY, the founder, going up a ladder, to view ſome part thereof, fell from it, and was killed, 1070.

When CANUTUS, the Daniſh king, was in conteſt with the noble Edward Ironſide, for the kingdom of England, the fortunate Dane obtained a complete victory at Aſſendon or Aſhdown, in Eſſex; in memory of which, after he had acquired the entire kingdom, he built a church in that place, which was afterwards conſecrated by Ulſtan, archbiſhop of York, *Cam. Brit. in Eſſex*, fol. 442.

William the ſon of Haman, the ſon of Vitalis, one who came with the Conqueror, built the Church of St. Mary Breden, in Canterbury, as his father Haman had built that of St. Edmund Ridingate, in the ſame city; that built by the ſon is yet ſtanding, though that of Haman's is ſo utterly periſhed, that the place where it ſtood cannot at this day be diſcovered *Somner's Antiq. Cant.* fol. 343.

Soon after the Normans coming, a mercileſs fire happened in Cambridge, and burned the greateſt part of the town, and moſt of the churches, which were built of wood; the Normans brought in with them new faſhions, and among the reſt, that of building; for notwithſtanding ſome few ſingular fabricks of ſtone, as have been mentioned, the monaſteries and church buildings were of wood, ſo as theſe timber buildings fell to decay, or grew out of uſe, ſtone buildings raiſed upon arches, were introduced; and therefore Stow and others relate how Mauritius, biſhop of London, began the foundation of the new church of St. Paul upon arches of ſtone, to prevent the danger of fire, (for not long before, with a great part of the city, it had been burnt) a manner of work, till then unknown to the Engliſh, and brought in by the French; the ſtone being fetched from Caen, in Normandy.

The church of St. Mary-le-Bow, in London, was alſo built much about the ſame time and manner, that is, upon bows or arches of ſtone, and was therefore called St. Mary-le-Bow: Hence the Official of the Arches has been ſo ſtiled for many ages, becauſe in former times he kept his court in Bow church.

Stratford Bridge, being the firſt bridge in England built with arches of ſtone, was therefore called Stratford-le-Bow. *Vide Stowe*'s *Survey*; and hence it was, that William of Malmeſbury, upon the coming in of the Conqueror, enlarging on the characters of the Engliſh and Normans of that time, gives this note of the Normans induſtry and ingenuity; *videas ubiq; in villis eccleſia*, &c. You may every where ſee churches in towns, and monaſteries in cities, riſe up in the new mode of building. As in the year 1077, being preſently after the Normans entry, Paulus, the fourteenth abbot of St. Alban's, couſin (and ſome thought ſon) of archbiſhop Lanfranc, according to the Norman way, built the abbey church of St. Alban's of ſuch ſtone as was left of the old city Verulam; his patron, Lanfranc, aſſiſting him with the ſum of One Thouſand Marks to carry on the work; but dedicated in the time of the next abbot, Richard. *Matt. Paris, Abb. St. Alban's*. Though, according to the model of the foregoing times, there had been before a famous church, built in honour and memory of the Proto-martyr, St. Alban, but not to be thought comparable to that afterwards built of ſtone by the Abbat Paulus. *Bede Eccl. Hiſ. Lib.* 1. *cap.* 7. which, at the demoliſhing of the monaſtery was redeemed by the townſmen for Four hundred pounds; and thenceforth converted into a pariſh church. See *Leland's Itinerary*.

When Joffred, abbot of Croyland, reſolved to rebuild the church of his monaſtery, 1106, he obtained, from the archbiſhops of Canterbury and York, a bull, diſpenſing with the third part of all penances for ſin, to thoſe who contributed any thing towards building of that church. This bull was directed not only to the king and people of England, but to thoſe of France and Scotland, and all other kings, earls, barons, archbiſhops, biſhops, abbots, priors, rectors, preſbyters and clerks, and to all true believers of Chriſt, rich and poor, in all Chriſtian kingdoms. He alſo ſent two monks to proclaim it to France and Flanders; two into Scotland; two into Wales, Cornwall and Ireland; and others into different parts of England.

" By this means (ſays the hiſtorian) the wonderful benefits granted to all the contributors to the building of this church, was publiſhed to the very ends of the earth, and great heaps of treaſure, and maſſes of yellow metal, flowed in from all countries, upon the venerable Abbot Joffred, and encouraged him to lay the foundation of his church."

Having ſpent about four years in collecting the materials, he fixed a day for the great ceremony of laying the foundation, which he contrived to make a very effectual means of raiſing the ſuperſtructure; for, on the long expected day, the feaſt of the Holy Virgin's *Felicitas and Perpetua*, an immenſe multitude of earls, barons, and knights, with their ladies and families of abbots, priors, monks, nuns, clerks, and perſons of all ranks, arrived at Croyland to aſſiſt at this ceremony. The pious abbot Joffred began by ſaying certain prayers, and ſhedding a flood of tears on the foundation. Then each of the nobility and viſitants laid a ſtone, or at leaſt depoſited a ſum of money, grants of land, tythes or patronages, or a promiſe of ſtone, lime, wood, or carriage, for the building of the ſaid church. After this the abbot entertained the whole company, amounting to about five thouſand perſons, with a dinner. To this entertainment they were all entitled; the benefits he received by his manœuvre were alone ſufficient to have raiſed a very noble fabric.

William Rufus, the Conqueror's ſon, continued to build palaces and caſtles; as alſo Henry the firſt; but more ſo in the reign of Stephen; whence it is ſaid, that no leſs than 1115 caſtles were built in nineteen years, from 1135 to 1154, covered with lead, glazed, plaiſtered, and white-waſhed, and the timber work of oak or cheſnut, well framed, and frequently carved.

The architects and artificers, by whom that work was planned and executed, muſt have attained conſiderable dexterity in their reſpective arts; ſeveral of theſe architects have obtained a place in hiſtory, and are highly celebrated for their ſuperior ſkill.

William of Sens, architect to Archbiſhop Lanfranc in building his cathedral, is ſaid, by Gervaſe of Canterbury, to have been a moſt exquiſite artiſt both in ſtone and wood. He made not only a model of the whole cathedral, but of every particular piece of ſculpture and carving, for the direction of the workmen; and invented many curious machines for loading and unloading ſhips, and conveying heavy weights by land, becauſe all the ſtones were brought from Normandy.

Matthew Paris ſpeaks even in a higher ſtrain of Walter of Coventry, who flouriſhed towards the end of this period, when he ſays, that "ſo excellent an architect had never yet appeared, and probably never would appear, in the world." This encomium was undoubtedly too high; but it is impoſſible to view the remains of many magnificent fabrics, both ſacred and civil, that were erected in this period, without admiring the genius of the architects by whom they were planned, and the dexterity of the workmen by whom they were executed.

In the year 1164, in the reign of Henry the ſecond, the church of Reading was conſecrated by Thomas Becket, archbiſhop of Canterbury, in the preſence of the king, ten biſhops, and a multitude of aſſiſtants and Spectators. *Matt. Paris*, fo. 122.

King Henry the third, who founded the Domus Converſorum, near London, for the convert Jews, gave ſeven hundred marks for the building of a church, with other convenient ſtructures, for the converted. But upon the baniſhment of that people, the houſe was annexed to the Maſter of the Rolls, by patent; and the church, now known by the name of the Chapel of the Rolls, in Chancery-lane. *Cart.* 16, *H.* 3. *M.* 10.

The Temple Church, of London, is of ancient foundation; ſome have delivered that Dunwallo Molmutius, a king here in Britain, about the year of the world 5748, anno domini 34, built here a temple, to which, as to ſome other places, he aſſigned ſanctuary privileges; and that he was there buried, with ſeveral others of the Britiſh kings.

But for that excellent ſtructure now ſtanding, it is of a far later extraction; being built by the Knights Templars in the reign of Henry the ſecond, anno 1185, and dedicated to Heraclius, patriarch, teſtified by an inſcription over one of the doors for that purpoſe. The entrance is through a circular tower, of Saxon Architecture, and the nave, or body of the church, is of the Saracenic, or improved Gothic.

In 1176 it was reſolved to build London Bridge of ſtone, a little weſt of the old one of wood; it was undertaken by Peter of Colechurch, and finiſhed by Elyas, of Weſtminſter, in 1209; it was therefore thirty-three years in building. The ſtone piers are built upon piles, about nine feet above the bed of the river (which confutes the abſurd idea of the river having been turned for that purpoſe) and three feet below the ſterlings, or frame-work, which was made round the piers to protect them; the courſes of ſtone in the piers, under water, are bedded together with pitch inſtead of mortar. The maſter maſon erected, at his own expence, a chapel on the eaſt ſide of the ninth pier, and endowed it: which was a beautiful arched Gothic ſtructure; the deſcription of it ſeems to indicate it rather the Saracenic; as follows: Cluſters of ſmall pillars ariſe at equal diſtances, on the ſides, bending over the ceiling, a roof meets in the centre of the arch, where they appeared bound together by a flower cut in the ſame ſtone.

It has been ſuppoſed the Saxons were ſtrangers to the forming or application of arches, particularly from the foregoing remarks on Bow Church, Bow Bridge, and the foundation of St. Paul, &c. it is not much to be wondered at, as we find all their public buildings were of wood for a long period of time; and when they had occaſion to build with ſtone as the Cathedral of Ely, ſome arches at Canterbury, &c. they had aſſiſtance from the continent, till again introduced by the Normans: as Henry the third ſent to Rome for Peter Cavalini, to erect the ſhrine of Edward the confeſſor, in Weſtminſter Abbey, in the year 1256, in the Roman ſtyle, which was again a revival of that Architecture in England. See Plate VIII. of this Syſtem.

A further diſtinction of the Saxon and Norman Architecture is, that the Saxon Churches were made with deſcents into them, the windows and doors ſmall and confined, low and gloomy, dark and damp, and very thick walls when built with ſtone; the entrances generally at the Weſt end by deſcents inward, and drawn over at the top gradually correſponding with the ſteps, and finiſhed at the top with ſome ſemicircular pieces of Gothic work, all which together made a kind of artificial perſpective.

The Norman Churches were generally built with aſcents, the windows and doors larger and loftier, the walls high, lightſome, and chearful, and their arches circular.

The Saxon, Gothic, Norman, and Roman, frequently became one general jumble, and often produced very incoherent, heavy, aukward buildings, and it was frequently a maxim with them not to attend to any degree of ſymmetry, as they ſeemed determined not to have any two things alike in one building, the ancient parts of many of our Cathedrals are of the ancient Norman, and of that mixture worked with ſtone from Caen in Normandy.

Biſhop Warburton, in his notes on Pope's Epiſtles, in the octavo edition, has the following ingenious obſervations on this ſubject: "Our Gothic anceſtors had juſter and manlier notions of magnificence, on Greek and Roman ideas, than theſe mimics of taſte, who profeſs to ſtudy only claſſic elegance; and becauſe the thing does honour to the genius of thoſe barbarians, I ſhall endeavour to explain it. All our ancient churches are called without diſtinction Gothic, but erroneouſly. They are of two ſorts; the one built in the Saxon times, the other in the Norman. Several cathedral and collegiate churches of the firſt ſort are yet remaining, either in whole or in part; of which this was the original: when the Saxon kings became Chriſtians, their piety, which was the piety of the times, conſiſted chiefly in building churches at home, and performing pilgrimages abroad, eſpecially to the Holy Land; and theſe ſpiritual exerciſes aſſiſted and ſupported one another; for the moſt venerable as well as moſt elegant models of religious edifices were then in Paleſtine. From theſe the Saxon builders took the whole of their ideas, as may be ſeen by comparing the drawings which travellers have given us of the churches yet ſtanding in that country, with the Saxon remains of what we find at home; and particularly in that ſameneſs of ſtyle in the latter religious edifices of the knights temporals, profeſſedly built upon the model of the church of the Holy Sepulchre at Jeruſalem, with the earlier remains of our Saxon edifices. Now the architecture of the Holy Land was Grecian, but greatly fallen from its ancient elegance. Our Saxon performance was indeed a bad copy of it, and as much inferior to the works of St. Helene and Juſtinian, as theirs were to the Grecian models they had followed: yet ſtill the footſteps of ancient art appeared in the circular arches, the entire columns, the diviſion of the entablature into a ſort of architrave, frize, and corniche, and a ſolidity equally diffuſed over the whole maſs. This, by way of diſtinction, I would call the Saxon architecture. But our Norman works had a very different original. When the Goths had conquered Spain, and the general warmth of the climate and the religion of the old inhabitants had ripened their wits and inflamed their miſtaken piety, both kept in exerciſe by the neighbourhood of the Saracens, through emulation of their ſervice, and averſion to their ſuperſtition, they ſtruck out a new ſpecies of architecture, unknown to Greece and Rome, upon original principles, and ideas much nobler than what had given birth even to claſſical magnificence. For this northern people having been accuſtomed, during the gloom of paganiſm, to worſhip the deity in groves, a practice common to all nations; when their new religion required covered edifices, they ingeniouſly projected to make them reſemble groves, as nearly as the diſtance of Architecture would permit; at once indulging their old prejudices, and providing for their preſent conveniences, by a cool receptacle in a ſultry climate; and with what ſkill and ſucceſs they executed the project by the aſſiſtance of Saracen architects, whoſe exotic ſtyle of building very luckily ſuited their purpoſe, appears from hence, that no attentive obſerver ever viewed a regular avenue of well grown trees intermixing their branches overheard, but it preſently put him in mind of the long viſto through the Gothic cathedral; or even entered one of the larger and more elegant edifices of this kind, but it preſented to his imagination an avenue of trees; and this alone is what can be truly called the Gothic ſtyle of building. Under this idea of ſo extraordinary a ſpecies of architecture, all the irregular tranſgreſſions againſt art, all the monſtrous offences againſt nature, diſappear; every thing has its reaſon, every thing is in order, and an harmonious whole ariſes from the ſtudious application of means proper and proportionate to the end. For could the archers be otherwiſe than pointed, when the workmen were to imitate that curve which branches of two oppoſite trees make by their inſertion with one another? or could the columns be otherwiſe than ſplit into diſtinct ſhafts, when they were to repreſent the ſtems of a clump of trees growing cloſe together? On the ſame principles they formed the ſpreading ramification of the ſtone-work in the windows, and the ſtained glaſs in the interſtices; the one to repreſent the branches, and the other the leaves of an opening grove, and both concurred to preſerve that gloomy light which inſpires religious reverence and dread. Laſtly, we ſee the reaſon of their ſtudied averſion to apparent ſolidity in theſe ſtupendous maſſes, deemed ſo abſurd by men accuſtomed to the apparent as well as real ſtrength of Grecian architecture. Had it been only a wanton exerciſe of the artiſt's ſkill, to ſhow he could give real ſtrength without the appearance of any, we might indeed admire his ſuperior ſcience, but we muſt needs condemn his ill judgment. But when one conſiders, that this ſurpriſing lightneſs was neceſſary to complete the execution of his idea of a Sylvan place of worſhip, one cannot ſufficiently admire the ingenuity of the contrivance. This too will account for the contrary qualities in what I call the Saxon architecture. Theſe artiſts copied, as has been ſaid, from the churches in the Holy Land, which were built on the models of the Grecian architecture, but corrupted by prevailing barbariſm; and ſtill farther depraved by a religious idea. The firſt places of Chriſtian worſhip, were ſepulchres and ſubterraneous caverns, low and heavy from neceſſity. When Chriſtianity became the religion of the ſtate, and ſumptuous temples began to be erected, they yet, in regard to the firſt pious ages, preſerved the maſſive ſtyle, made ſtill more venerable by the church of the Holy Sepulchre; where this ſtyle was, on a double account, followed and aggravated."

The marks which conſtitute the character of the Saracenic, or modern Gothic Architecture, are its pointed arches, prominent buttreſſes, taper ſpires, delicate pinnacles, large ramified windows, niches or canopies, ſculptured ſaints, neat lace-work, perforated battlements, and fretted roofs, with pendant drops, and exquiſite profuſion of ornaments. But its peculiar diſtinguiſhing characteriſtics are the ſmall cluſtered pillars and pointed arches (agreeing with a former idea given of its origin.)

This ſtyle of Architecture was introduced in England between the eleventh and twelfth century; and Saliſbury cathedral, finiſhed in 1258, was ſaid, by Sir Chriſtopher Wren, to be the moſt compleat building in that ſtyle.

Torregiano, a Florentine, who built Henry the ſeventh's chapel, and Cloos, the builder of King's College, Cambridge, excelled in the art; with many others about that time; ſo much ſo, that moſt of our very eminent men, who have attempted that ſtyle, have fallen very ſhort of their examples.

From this time till the reign of Henry VIII. the faſhionable pillars in churches were of Purbec marble, very ſlender and round, encompaſſed with marble ſhafts a little detached, having each a capital adorned with foliage, which joining, formed one elegant capital for the whole pillar. The windows were long and narrow, with pointed arches and painted glaſs, which was introduced about that time, or at leaſt became more common. In this century alſo they began to delight in lofty ſteeples, with ſpires and pinnacles. In the fourteenth century, the pillars conſiſted of an aſſemblage of ſhafts not detached, but united, forming one ſolid and elegant column; the windows, eſpecially thoſe in the eaſt and weſt ends, were greatly enlarged, divided into ſeveral lights by ſtone mullions running into ramifications above, and forming numerous compartments in various fanciful ſhapes. Thoſe windows, filled with ſtained glaſs of the moſt lively colours, repreſenting kings, ſaints, and martyrs, and their hiſtories, made a moſt ſolemn and glorious appearance. There were ſeveral other variations, eſpecially in the taſte of the carvings and other ornaments, which are too minute for general hiſtory.

The Abbeys, Cathedrals, and College Buildings, erected in the improved ſtyle, were many, and ſome of them extremely grand; and if the architects of that day had not the happineſs of lighting on the ſimplicity and proportion of the Greek orders, they were however ſo lucky as to ſtrike out a thouſand graces, and effects, which rendered their buildings magnificent, yet genteel; vaſt, yet light; venerable and pictureſque: for inſtance, the Cathedral at Rheims, and ſeveral of the Cathedrals in England. It is difficult for the nobleſt Grecian Temple to convey half ſo many impreſſions on the mind as a Cathedral does, of the beſt Gothic or Saracenic Architecture; a proof of ſkill in the Architects, and of addreſs in the prieſts who erected them, the latter exhauſted their knowledge of the paſſions in compoſing edifices, whoſe pomp, mechaniſm, vaults, tombs, painted windows, gloom and perſpectives, infuſed ſuch ſenſations of romantic devotion, that they were happy in finding artiſts, capable of executing ſuch machinery; we muſt have taſte to be ſenſible of the beauties of Grecian Architecture; we only want paſſions to feel Gothic: In St. Peter's, or St. Paul's, we are convinced they were built by great Princes. In Weſtminſter Abbey, and Gothic Cathedral, we think not of the builder, the religion of the place makes the firſt impreſſion; and though ſtripped of its altars, and ſhrines, it is nearer converting us to popery, than all the regular pageantry of Roman domes. Gothic Churches infuſe ſuperſtition; Grecian admiration; the papal ſee amaſſed its wealth by Gothic Cathedrals, and diſplays it in Grecian Temples; certainly there is no compariſon between the rational beauties of regular Architecture, and the unreſtrained licentiouſneſs of that which is called Gothic; yet, it is certain, the perſons who executed the latter, had much more knowledge of their art, more taſte, more genius, and more propriety than we chuſe to imagine. There is a magic hardneſs in the execution of ſome of their works, which would not have ſuſtained themſelves if dictated by mere caprice.

There is a tradition that Sir Chriſtopher Wren went once a year to ſurvey the roof of the chapel of King's College, Cambridge, and ſaid, that if any man would ſhow him where to place the firſt ſtone, he would engage to build ſuch another. That there is great grace in ſeveral places, even in their cluſters of ſlender pillars, and in the application of their ornaments; though the principles of the latter are ſo confined, that they may almoſt all be reduced to the trefoil, extended and varied; it is not neceſſary to appeal to the edifices themſelves. It is ſufficient to obſerve, that Inigo Jones, Sir Chriſtopher Wren, and Mr. Kent, &c. who certainly underſtood beauty, blundered into the heavieſt and clumſieſt compoſitions, whenever they aimed at imitations of the Gothic, particularly in Lincoln's Inn Chapel, the ſteeple of the Church at Warwick, the King's Bench in Weſtminſter Hall, the ſcreen at Glouceſter, Eſher in Surry, &c. &c. is an art deſpicable in which a great maſter cannot ſhine?

Conſidering how ſcrupulouſly our Architects confine themſelves to antique precedent, perhaps ſome deviations into Gothic may a little relieve them from that ſervile imitation; that is, that they ſhould ſtudy both taſtes, not blend them, as we ſee in many inſtances, where Architects make additions or alterations, differing from the ſtye of the original building; as if they meant to record every alteration with the ſervile faſhion of the day, however ridiculous; at leaſt, externally, the ſtyle ſhould be preſerved. Architecture is an extenſive field, and it is a pity that the art ſhould be reſtrained too much, as, it is evident, it contains ſufficient variety to furniſh infinite ſcenes of ſingular beauty. The application of loggias, arcades, terraces, and flights of ſteps, at different ſtages of a building, would contribute much to magnificence. It is true, our climate, and the expence of building in England, are great reſtrictions on imagination; but when we talk of the extent of which Architecture is capable, we may ſuppoſe that pomp and beauty are the principal objects; we ſpeak of palaces, public buildings, and houſes of nobility; not of ſmall houſes, &c.

It is certain that the Gothic or Saracenic taſte remained in vogue till toward the end of the reign of Henry the Eighth, but ſoon after the Grecian ſtyle was introduced; and no wonder when ſo many Italians were entertained in the king's ſervice. They had ſeen that Architecture revived in their own country in all its purity; but whether they were not perfect maſters of it, or that it was neceſſary to introduce the innovation by degrees, it certainly did not at firſt obtain full poſſeſſion; it was plaiſtered upon Gothic, and made a barbarous mixture (ſimilar to the introduction of the Saracenic with the Saxon and Normans). Regular columns, with ornaments neither Grecian nor Gothic, and half embroidered with foliage, were crammed over frontiſpieces, façades, chimnies, &c. and loſt all grace, by wanting ſimplicity. This mungrel ſpecies laſted till late in the reign of James the Firſt.

The beginning of reformation in building ſeems owing to Hans Holbein; his porch at Wilton, though purer than the work of his ſucceſſors, is of the baſtard ſort; but the ornaments and proportions of his works are graceful and well choſen. Henry had actually an Italian, whom, it is ſuppoſed, introduced regular Architecture; but it is doubted whether he or Holbein firſt arrived in England. He was called John of Padua; and his very office ſeems to intimate ſomething novel in his practice. He was termed *Devizor of his Majeſty's Buildings*.

As to the ſtate of Civil Architecture during the ſame period; the houſes of the common people in the country, and of the lower burgeſſes in towns and cities, were very little improved in their ſtructure; that moſt numerous and uſeful order of men being much depreſſed in the times we are now delineating. Even in the capital city of London, all the houſes of mechanics and common burgeſſes were built of wood, and covered with ſtraw or reeds, towards the end of the twelfth century; ſo that Architecture was not brought to any great degree of perfection till the reign of Charles the Firſt, when Inigo Jones recovered the full powers of Grecian Architecture; he was ſucceeded by Sir Chriſtopher Wren, who died in 1723, and left St. Paul's, with many other capital buildings, as his monuments and ſtandards for ſucceeding ages: very little violation of that true taſte has been committed, except by Sir John Vanburgh and his diſciples, who built priſons for dwelling-houſes: and we may boaſt to this day, that the purity of Grecian and Roman Architecture, together with elegant, uſeful, and convenient habitations, are as well known and practiſed in this country, as in either Greece or Rome, in its flouriſhing ſtate; which our modern churches, public buildings, ſquares, ſtreets, bridges, pantheons, ſcreens, colonades, noblemens ſeats, and private houſes, teſtify.

Having treated on the Origin, Riſe and Progreſs of Architecture, *and traced its various fluctuations, I proceed on the principles of the Art, as it is now practiced; and ſhall attempt to define the Intrinſic aud Relative Beauty, together with the convenience and propriety, &c. of the Art.*

In the beauty of viſible objects, we diſcover two kinds. The firſt may be termed *intrinſic* beauty, becauſe it is diſcovered in a ſingle object, without relation to any other. The ſecond may be termed *relative* beauty, being founded on a combination of relative objects. Architecture admits of both kinds. We ſhall firſt give a few examples of *relative* beauty.

The proportions of a door are determined by the uſe to which it is deſtined. The door of a dwelling-houſe, which ought to correſpond to the human ſize, is confined to ſeven or eight feet in height and three or four in breadth. The proportions proper for a ſtable or coach-houſe are different. The door of a church ought to be wide, in order to afford an eaſy paſſage for a multitude; and its height muſt be regulated by its wideneſs, that the proportion may pleaſe the eye. The ſize of the windows ought always to be proportioned to that of the room they are deſtined to illuminate; for, if the apertures be not large enough to convey light to every corner, the room muſt be unequally lighted, which is a great deformity. Steps of ſtairs ſhould likewiſe be accommodated to the human figure, without regarding any other proportion; they are accordingly the ſame in large and in ſmall buildings, becauſe both are inhabited by men of the ſame ſize.

We ſhall next conſider *intrinſic* beauty, blended with that which is *relative*. A cube itſelf is more agreeable than a parallelopipedon; this conſtantly holds in ſmall figures; but a large building in the form of a cube is lumpiſh and heavy; while a parallelopipedon, ſet on its ſmaller baſe, is more agreeable on account of its elevation: hence the beauty of Gothic towers. But if this figure were to be uſed in a dwelling-houſe, to make way for relative beauty, we would immediately perceive that utility ought chiefly to be regarded; and this figure, inconvenient by its height, ought to be ſet on its larger baſe: the loftineſs in this caſe would be loſt; but that loſs will be more than ſufficiently compenſated by the additional convenience. Hence the form of buildings ſpread more upon the grouud than raiſed in height, is always preferred for a dwelling-houſe.

With regard to the internal diviſions, utility requires that the rooms be rectangular, to avoid uſeleſs ſpaces. An hexagonal figure leaves no void ſpaces; but it determines the rooms to be all of one ſize, which is both inconvenient and diſagreeable for want of variety. Though a cube be the moſt agreeable figure, and may anſwer for a room of modern ſize; yet in a very large room, utility requires a different figure. Unconfined motion is the chief convenience of a great room; to obtain this the greateſt length that can be had is neceſſary. But a ſquare room of large ſize is inconvenient. It removes chairs, tables, &c. at too great a diſtance from the hand, which, when unemployed, muſt be ranged along the ſides of the room. Utility, therefore, requires a large room to be a parallelogram. This figure is likewiſe beſt calculated for the admiſſion of light; becauſe, to avoid croſs-lights, all the windows ought to be in one wall; and if the oppoſite wall be at ſuch a diſtance as not to be fully lighted, the room muſt be obſcure. The height of a room exceeding nine or ten feet has little relation to utility; therefore proportion is the only rule for determining the height when above that number of feet.

Artiſts who deal in the beautiful, love to entertain the eye; palaces and ſumptuous buildings, in which intrinſic beauty may be fully diſplayed, give them an opportunity of exerting their taſte. But ſuch a propenſity is peculiarly unhappy with regard to private dwelling houſes; becauſe, in theſe, relative beauty cannot be diſplayed to perfection without hurting intrinſic beauty. There is no opportunity for great variety of form in a ſmall houſe; and in edifices of this kind, internal convenience has not hitherto been happily adjuſted to external regularity. Perhaps an accurate coincidence in this reſpect is beyond the reach of art. Architects, however, conſtantly ſplit upon this rock; for they never can be perſuaded to give over attempting to reconcile theſe two incompatibles: how otherwiſe ſhould it happen, that of the endleſs variety of private dwelling-houſes, there ſhould not be one found that is generally agreed upon as a good pattern? the unwearied propenſity to make a houſe regular as well as convenient, obliges the architect, in ſome articles, to ſacrifice convenience to regularity; and, in others, regularity to convenience; and accordingly the houſe which turns out neither regular nor convenient, never fails to diſpleaſe.

Nothing can be more evident, than that the form of a dwelling-houſe ought to be ſuited to the climate; yet no error is more common than to copy in Britain the form of Italian houſes, not forgetting even thoſe parts that are purpoſely contrived for collecting air, and for excluding the ſun: witneſs our colonnades and logios, deſigned by the Italians to gather cool air, and exclude the beams of the ſun; conveniences which the climate of this country does not require, except in ſome particular ſituations.

We ſhall next view architecture as one of the fine arts; which will lead us to the examination of ſuch buildings, and parts of building, as are calculated ſolely to pleaſe the eye. Variety prevails in the works of nature, but art requires to be guided by rule and compaſs. Hence it is, that in ſuch works of art as imitate nature, the great art is, to hide every appearance of art; which is done by avoiding regularity and indulging variety. But in works of art that are original and not imitative, ſuch as architecture, ſtrict regularity and uniformity ought to be ſtudied, ſo far as conſiſtent with utility.

Proportion is not leſs agreeable than regularity and uniformity; and therefore, in buildings intended to pleaſe the eye, they are all equally eſſential. It is taken for granted by many writers, that in all the parts of a building there are certain ſtrict proportions which pleaſe the eye, in the ſame manner as in ſound there are certain ſtrict proportions which pleaſe the ear; and that, in both, the ſlighteſt deviation is equally diſagreeable. Others ſeem to reliſh more a compariſon between proportion in numbers and proportion in quantity; and maintain, that the ſame proportions are agreeable in both. The proportions, for example, of the numbers 16, 24, and 36, are agreeable; and ſo, ſay they, are the proportions of a room, whoſe height is 16 feet, the breadth 24, and the length 36. But it ought to be conſidered, that there is no reſemblance or relation between the objects of different ſenſes. What pleaſes the ear in harmony, is not the proportion of the ſtrings of the inſtrument, but of the ſound which theſe ſtrings produce. In architecture, on the contrary, it is the proportion of different quantities that pleaſes the eye, without the leaſt relation to ſound. The ſame thing may be ſaid of numbers. Quantity is a real quality of every body; number is not a real quality, but merely an idea that ariſes upon viewing a plurality of things in ſucceſſion: an arithmetical proportion is agreeable in numbers; but have we any reaſon to conclude, that it muſt alſo be agreeable in quantity? At this rate a geometrical proportion, and many others, ought alſo to be agreeable in both. A certain proportion may coincide in quantity and number; and, amongſt an endleſs variety of proportions, it would be wonderful if there never ſhould be a coincidence. One example is given of this coincidence in the numbers 16, 24, and 36; but, to be convinced that it is merely accidental, we need but reflect, that the ſame proportions are not applicable to the external figure of a houſe, and far leſs to a column.

It is ludicrous to obſerve writers acknowledging the neceſſity of accurate proportions, and yet differing widely about them. Laying aſide reaſoning and philoſophy, one fact univerſally agreed on ought to have undeceived them, that the ſame proportions which pleaſe in a model, are not agreeable in a large building: a room 48 feet in length, and 24 in breadth and height, is well proportioned; but a room 12 feet wide and high, and 24 long, approaches to a gallery.

Perrault, in his compariſon of the ancients and moderns, goes to the oppoſite extreme; maintaining, that the different proportions aſſigned to each order of columns are arbitrary, and that the beauty of theſe proportions is entirely the effect of cuſtom. But he ſhould have conſidered, that if theſe proportions had not originally been agreeable, they could never have been eſtabliſhed by cuſtom.

For illuſtrating this point, we ſhall add a few examples of the agreeableneſs of different proportions. In a ſumptuous edifice, the capital rooms ought to be large, otherwiſe they will not be proportioned to the ſize of the building; for the ſame reaſon, a very large room is improper in a ſmall houſe. But in things thus related, the mind requires not a preciſe or ſingle proportion, rejecting all others; on the contrary, many different proportions are equally agreeable. It is only when a proportion becomes looſe and diſtant, that the agreeableneſs abates, and at laſt vaniſhes. Accordingly, in buildings, rooms of different proportions are found to be equally agreeable, even where the proportion is not influenced by utility. With regard to the proportion the height of a room ſhould bear to the length and breadth, it muſt be extremely arbitrary, conſidering the uncertainty of the eye as to the height of a room when it exceeds 16 or 17 feet. In columns, again, every architect muſt confeſs that the proportion of height and thickneſs varies betwixt 8 diameters and 10, and that every proportion between theſe two extremes is agreeable. Beſides, there muſt certainly be a further variation of proportion, depending on the ſize of the column. A row of columns 10 feet high, and a row twice that height, requires different proportions: the intercolumniations muſt alſo differ in proportion according to the height of the row.

Proportion of parts is not only itſelf a beauty, but is inſeparably connected with a beauty of the higheſt reliſh, that of concord and harmony; which will be plain from what follows: a room, the parts of which are all finely adjuſted to each other, ſtrikes us not only with the beauty of proportion, but with a pleaſure far ſuperior. The length, the breadth, the height, the windows, raiſe each of them a ſeparate emotion: theſe emotions are ſimilar; and, though faint when ſeparately felt, they produce in conjunction the emotion of concord or harmony, which is very pleaſant. On the other hand, where the length of a room far exceeds the breadth, the mind, comparing together parts ſo intimately connected, immediately perceives a diſagreement or diſproportion which diſguſts. Hence a long gallery, however convenient for exerciſe, is not an agreeable figure of a room.

In buildings deſtined chiefly or ſolely to pleaſe the eye, regularity and proportion are eſſentially neceſſary, becauſe they are the means of producing intrinſic beauty. But a ſkilful artiſt will not confine his view to regularity and proportion; he will alſo ſtudy congruity, which is perceived when the form and ornaments of a ſtructure are ſuited to the purpoſe for which it is appointed. Hence every building ought to have an expreſſion ſuited to its deſtination. A palace ought to be ſumptuous and grand; a private dwelling, neat and modeſt; a play-houſe, gay and ſplendid; and a monument, gloomy and melancholy. A heathen temple has a double deſtination: it is conſidered as a houſe dedicated to ſome divinity; therefore it ought to be grand, elevated, and magnificent: it is alſo conſidered as a place of worſhip; and therefore ought to be ſomewhat dark and gloomy, becauſe dimneſs or obſcurity produces that tone of mind which is favourable to humility and devotion. Columns, beſides their chief deſtination of being ſupports, contribute to that peculiar expreſſion which the deſtination of a building requires Columns of different proportions ſerve to expreſs loftineſs, lightneſs, &c. as well as ſtrength. Situation may alſo contribute to expreſſion: conveniency regulates the ſituation of a private dwelling-houſe; and the ſituation of a palace ought to be lofty. This leads to a queſtion, Whether the ſituation, where there happens to be no choice, ought, in any meaſure, to regulate the form of the edifice? The connection between a great houſe and a neighbouring field, though not extremely intimate, demands however ſome congruity. It would, for example, diſpleaſe us to find an elegant building thrown away upon a wild uncultivated country; congruity requires a poliſhed field for ſuch a building. The old Gothic form of building was well ſuited to the rough uncultivated regions where it was invented; but was very ill adapted to the fine plains of France and Italy.

"An ingenious author on the ſubject of proportions of external and internal objects, ſays, that proportion requires our niceſt application to attain. To ſee on a conſiderable eminence the length of a front trifling, and the height diſproportioned, would appear as abſurd, as to behold a front in a vale long and extended, and elevated only one ſtory. And this choice muſt likewiſe be dependant upon rules; for as the jarring of inſtruments by blind chance cannot poſſibly pleaſe the ear, ſo the diſproportion of the parts of any object muſt naturally ſhock the eye; and in both unerring rules muſt ſo proportion the ſounds, and diſpoſe the parts, as the whole may be in a compleat harmony. Nature has taught mankind, in muſic, certain rules for proportions of ſounds, ſo Architecture has its rules dependant on thoſe proportions, or at leaſt ſuch proportions which are in Arithmetical harmony; and thoſe I take to be dependant on nature. The *ſquare*, in Geometry; the *uniſon*, or *circle*, in Muſic; and the *cube*, in Building; have all an inſeparable proportion; the parts being equal, and the ſides and angles, &c. give the eye and ear an agreeable pleaſure; from hence, may likewiſe be deduced the cube and half; the double cube; the diapaſon; and diapente; being founded on the ſame principles in muſic. From hence may be conſidered likewiſe the ſubduple proportion of 2, 3, and 4; and their duplicates 3, 4, and 5; likewiſe of 3, 4, and 6; all which follow, and their uſes applied to the external part of building."

It is to be obſerved, a building of 1000 feet long may have the ſame or ſimilar proportions applied thereto by advancing forward for the cube, retreating for the diapaſon and changing the line again to a diapente which the French artiſts call *mouvement*, and which mixture of proportioned parts make the whole agreeable; alſo heightening and lowering the ſeveral parts in a ſimilar way, obſerving that the whole accord in uniſon.

In any of the following proportions to be performed, it is to be obſerved, that the cube muſt never exceed 50 feet; the cube and half 60 feet, and the double cube more than 80 feet fronts.

If the cube be 50 feet front, conſequently the depth and height will be the ſame: the cube and half, if the front be 60 feet, the depth will be 40, and the height 40: the double cube of 60 feet front, will be 30 feet deep, and 30 feet high; this is called a double cube in building; is alſo placing of two cubes together in plano.

The Arithmetical proportions flow in the ſame progreſſive channel, and are to be made uſe of as neceſſity requires, 4, 3, and 2, with their duplicates, make an agreeable front; if the front be 60 feet, then the depth will be 45, and height 30; agreeably to the above proportions; or if it be 80 feet front, the depth will by the ſame rule be 60 feet, and the height 40.

In the Arithmetical proportion of 5, 4, and 3, if the front be 60 feet, the depth will be 48, and height 36; or if the front be 80 feet, it will produce 60 feet deep, and 48 feet high; which numbers are in the proportion of 5, 4, and 3, reſpectively.

The Arithmetical proportion of 6, 4, and 3, will, if the front be 60 feet, produce the depth 40, and height 30 feet; or if the front be 90 feet, the depth will be 60, and height 45.

It is not in every inſtance buildings are ſo detached that the two fronts are ſeen at the ſame time, and when that is the caſe, leſs attention is neceſſary to proportion the depth of building; and it frequently happens, that one or two fronts are attached to offices, and planted out with ſhrubs and evergreens, the object of proportional effect is where the elevations are expoſed.

Having conſidered external proportions, I proceed to conſider the internal proportions of rooms on the ſame principle. In muſic are only ſeven diſtinct notes; in Architecture, therefore are ſeven diſtinct proportions, which produce all the different effects neceſſary in building.

The cube; cube and half; double cube; the duplicates of 3, 2, and 1; of 4, 3, and 2; of 5, 4, and 3; and of 6, 4, and 3; produce all the harmonic proportions of rooms.

For example: Suppoſe a building whoſe principal floor is 12 feet high, how to proportion thoſe rooms which are the internal part by the preceding rules.

		Feet		Feet	
If the height by 12 feet.	The cube will be	12	long	12	broad
	The cube and half	18	——	12	
	The double cube	24	——	12	
	The duplicate of 3, 2, and 1	36	——	24	
	Ditto 4, 3, and 2	24	——	18	
	Ditto 5, 4, and 3	20	——	16	
	Ditto 6, 4, and 3	24	——	16	

Theſe are the ſeven proportions of rooms which are founded upon the ſame rules as the uniſon, the diapente, the diapaſon, the ſeſquialter, &c. are in muſic, and may be varied to all kinds of magnitudes whatever, ſuppoſing your ſtory to be the ſtandard.

This rule is again illuſtrated by one more example.

		Feet		Feet	
The height of the ſtory being 18 feet.	The cube will be	18	long	18	broad
	The cube and half	27	——	18	
	The double cube	36	——	18	
	The ſubduple of 4, 3, and 2	36	——	27	
	Ditto 5, 4, and 3	30	——	24	
	Ditto 6, 4, and 3	36	——	24	
	Ditto 3, 2, and 1	54	——	36	

The rule explained. Suppoſe the height 18 feet, and the ſubduple proportion is 6, 4, and 3, divide 18 by 3, and the quotient is 6; multiply that quotient by 4, produceth 24 the breadth; and multiplying it by 6, produceth 36, the length of the room: and ſo of all the other proportions.

External proportion is very much to be attended to, in the country particularly, and where the whole, or any part of the building becomes an object on the approach, or ſeen by paſſengers; but in town the caſe is generally different, as few houſes are detached; but where they are, or made conſpicuous, a very nice obſervation, and regard to proportion, becomes neceſſary; as in ſeveral houſes in Pall-mall; the ſquares; Mr. Wyat's houſe, facing Queen-Ann-ſtreet; the end houſe of Stratford Place; and the like: but in general the town houſes are carried up ſimilar to the reſt that compoſe a ſtreet or ſquare, and then become a part of the whole compoſition; which whole ſhould be contrived to harmonize, and make one handſome general effect of elevation; as the ſides of Bedford Square; and Mr. Shepherd's intended idea of Groſvenor Square, when he began the North Side; Portland Place, &c.

The internal diſpoſition of town houſes require much invention, being limited to certain proportions or claſſes within the bills of mortality, by act of parliament, which muſt be conformed to; viz. the largeſt ſizes of houſes, which are conſidered of the firſt rate, are ſuch as exceed nine ſquares of building; thoſe of the ſecond rate, from five to nine ſquares; thoſe of the third rate, from three and a half to five ſquares; and thoſe of the fourth rate not exceeding three and a half ſquares; under theſe limits town houſes are to be built; which act alſo regulates the heights of them, and the thickneſs of walls, chimnies, &c. therefore, thus fettered, the builder is to make his plan: in the firſt place, the artiſt is not confined, but in the ſecond and third he is much limited, where diſpoſition of the ſtaircaſe becomes a ſerious object, in ſome of which, it is at the entrance, in others between the front and back room, receiving its light by a ſky-light and open newell; and, laſtly, in the back part, at the end of a paſſage, within the entrance; all which require judicious management to make the moſt of the rooms, which generally conſiſt of three that are principal; a ſetting room or library, a dining and drawing room; the latter, in ſecond and third rate houſes, are uſually on the one pair ſtory, either front or back, as the ſtaircaſe will admit; the finiſhings of ſuch houſes ſhould be neat, and ornaments few; a receſs for a ſideboard, and groined entrance may be admitted, with plaiſter cornices, and two or three enrichments at moſt, if the ſtory does not exceed twelve feet in height, without a frieze; and, in order to gain the effect of height, the ſide walls cannot be too plain, or the cornice too narrow; and an ornament or ſoffits carried round the room on the ceiling, a method now much practiſed. The one to be preferred of the before named plans, where the dimenſions will admit, is the ſtaircaſe in the center of the building, and the next is the ſtaircaſe at the entrance, both of which admit the back rooms their full extent between the walls; and, if communication is wanted into the back yard, or garden, it is generally done by the ſaſhes down to the floor, or one of the window backs opening, and framed to anſwer the others: the number of windows is generally governed by the aſpect, and openneſs of the ſituation, or the extent of the front; one or two piers in the room will be the conſequence, which are certainly conſiderations with reſpect to light, proportion, and mode of furniture, the windows in general being from three feet to four feet ſix; and five feet and upwards, if plate glaſs, as three ſquares wide are moſtly preferred, and thoſe window heights about twice their width; but if down to the floor, they are generally more; the two pair ſtory ſometimes two ſquares, or twice their width, and ſometimes one ſquare and a half; the attics, one ſquare, and ſometimes, when above a cornice, only half a ſquare, in conformance to the ſcheme of elevation.

The offices, or domeſtic part of town houſes, are moſtly under the principal floor, which are frequently very offenſive, particulary the ſmell from the kitchen, and the noiſe from the ſervants hall, which, if poſſible, are frequently detached, and covered with lead or copper, and the flues run into the party wall of the main building; this is a practice moſtly followed in houſes approaching to, or about nine ſquares; if larger, the plan is more at liberty: and, in order to keep them in other reſpects ſweet, proper drains and ſtink traps are eſſential conſiderations: moſt other conveniences depend on the circumſtances of the families they are intended for; and the arrangement of them, on the judgment of the Architect or builder, to whom they are entruſted.

Ornaments in Architecture require a very nice diſcrimination, and much judgment in the Architect to apply them, that they may be ornaments at all; they conſiſt of ſeveral claſſes; viz. blank doors, blank windows, &c. for ſake of ſymmetry; ruſtics, pilaſters, columns, arches, intercolumniations, baluſtrades, facias, bas and alto relievos, in tablets and medallions, niches, vaſes, ſtatues, &c.

Where blank windows are neceſſary, a glazed ſaſh ſhould be fixed therein, or it no longer anſwers the intended purpoſe; blank doors ſeldom occur but within ſide a houſe, and anſwers very well for ſcenery to make the houſe appear larger, or for ſymmetry to anſwer a real door, but ſhould be uſed ſparingly in rooms, unleſs very large ones, to compleat the ſymmetry of one ſide, and frequently a jib door leading to a private apartment ſhould be preferred; as the appearance of too many doors give an idea of cold, and looks uncomfortable. Ruſtic baſements to buildings frequently produce a happy effect; alſo ruſtic quoins; they are either ſquare or champhered; but when applied to the ſhafts of columns they look very heavy; as in ſome of the works of Meſſ. Gibbs, Shepherd, and others; alſo the projecting key-ſtones to arches, as is ſeen in Groſvenor Square, South Audley Street, &c. Pilaſters and columns, when properly applied, are the moſt graceful ornaments in building; they are conſidered ornamental when attached or inſulated; and they muſt be properly ſupported, and alſo appear to ſupport their entablature, and ſometimes an attic; and, when detached, become the principal ſupports of arches, groins, and vaulted roofs; temples, porticos, pediments, &c. and, when ſo applied, certain rules for their diſtance govern their application, as will be ſhewn hereafter, and deſcribed by intercolumniations. Arches or arched receſſes in fronts of houſes, ſometimes have a good effect, but are ſeldom pleaſing above the baſements, except in a few inſtances; arched or groined entrances, to reduce the height of narrow paſſages, anſwer extremely well; and if made of ſolid materials between the ground and principal floor, ſerve a double purpoſe, as they keep out noiſe and ſmell; and wherever they can be applied, they are a goodefence againſt fire.

But to return to ornaments; tablets, medallions, with bas and alto relievos, ſtatues, buſts, niches, and vaſes, ſhould be very carefully introduced; alſo enriched ceilings, moldings, foliage, &c. as in general we ſee them ſtuck about ſo profuſely and improperly, that they become a ſacrifice to ornament; the late improvement in the art of molding and caſting ornaments in plaiſter, compoſition, and artificial ſtone, have rendered them ſo common, and ſo miſapplied, that it is offenſive to true taſte; notwithſtanding, good models from regular deſigns, calculated for the purpoſe by an Architect of judgment, never fail to pleaſe.

Before we proceed to the proportions of the ſeveral orders of Architecture, agreeable to Sir William Chambers, namely, Tuſcan, Doric, Ionic, Corinthian, and Compoſite, to give a good general idea of the whole, have introduced columns of each order, accompanying an arch with proper dreſſings, bearing the general proportion of the order to which they belong, with its impoſt and archivolt, &c.

See Plate I. TUSCAN. Plate II. DORIC. Plate III. IONIC. Plate IV. CORINTHIAN. Plate V. COMPOSITE, in this *Syſtem of* ARCHITECTURE, taken from the much eſteemed works of Monſieur De La Foſſe, an Architect of the firſt eminence in Paris: they are proportioned by modules and parts, each module being a ſemi-diameter, divided into eighteen parts; all of them are accurately figured; the ornaments by which they are decorated ſerve to ſhew a variety; but muſt be applied agreeably to the purpoſe of the intention of the building.

Of Regular Mouldings there are eight; which are the Ovolo, the Talon, the Cyma, the Cavetto, the Torus, the Aſtragal, the Scotia, and the Fillet.

The names of theſe are alluſive to the forms; and their forms are adapted to the uſes which they are intended to ſerve.

The Ovolo and Talon, as they are ſtrong at their extremities, are fit for ſupports; the Cyma and Cavetto, though improper for that purpoſe, being weak in their extreme parts, and terminating in a point, are well contrived for coverings to ſhelter other members: for the tendency of their contour is very oppoſite to the direction of falling water; which for that reaſon cannot glide along their ſurface, but muſt neceſſarily drop. The Torus and Aſtragal, being ſhaped like ropes, are intended to bind and fortify the parts on which they are employed: but the uſe of the Fillet and Scotia, is only to ſeparate and diſtinguiſh other mouldings, to give a graceful turn to the profile, and to prevent that confuſion which would be occaſioned by joining ſeveral curved members together.

That the inventors of theſe Mouldings meant to expreſs ſomething by their different figures will ſcarcely be denied; and that theſe were their deſtinations may be deduced, not only from their figures, but from the practice of the Ancients in their moſt eſteemed works: for if we examine the Panthæon, the Three Columns, the temple of Jupiter Tonans, the fragments of the Frontiſpiece of Nero, the Baſilica of Antoninus, the Forum of Nerva, the Arches of Titus and Septimius Severus, the Theatre of Marcellus, and indeed almoſt every ancient building, either at Rome, or in other parts of Italy, and France, it will be found that, in all their profiles, the Cyma and the Cavetto are conſtantly uſed as finiſhings, and never applied where ſtrength is required; that the Ovolo and Talon are always employed as ſupporters to the eſſential members of the Compoſition, ſuch as the Modillions, Dentils, and Corona; that the chief uſe of the Torus and Aſtragal is to fortify the tops and bottoms of Columns, and ſometimes Pedeſtals, where they are frequently cut in the form of ropes; as on the Trajan Column, in the Temple of Concord, and on ſeveral fragments both at Rome and at Niſmes in Languedoc; and that the Scotia is employed only to ſeparate the members of Baſes, for which purpoſe the Fillet is likewiſe uſed, not only in Baſes but in all kinds of Profiles.

There are various manners of deſcribing the Contours of the Mouldings: but the ſimpleſt and beſt is to form them of quadrants of circles, by which means the different depreſſions and ſwellings will be ſtrongly marked, the tranſitions made without any angle, and the projections be agreeable to the doctrine of Vitruvius, and the practice of the Ancients; thoſe of the Ovolo, Talon, Cyma, and Cavetto, being equal to their height, that of the Scotia to one third thereof, and thoſe of the curved parts of the Torus and Aſtragal to one half of it.

On particular occaſions, however, it may be neceſſary ſometimes to encreaſe and at other times to diminiſh theſe projections, according to the ſituation or other circumſtances attending the profile. When it ſo happens the Ovolo, Talon, Cyma, and Cavetto, may either be deſcribed from the ſummits of equilateral triangles, or compoſed of quadrants of the Ellypſis; the latter of which is to be preferred, becauſe it produces a ſtronger oppoſition of light and ſhade, and by that means, makes the figure more diſtinct. The Scotia may likewiſe be formed of Ellyptical portions, or of quadrants of the circle, by which means its projection may either be encreaſed or diminiſhed: but the curved part of the Torus and Aſtragal muſt always be ſemicircular, and the encreaſe in their projection be by ſtreight lines.

In ſome Antiques, and likewiſe in various modern buildings, where the parts are far removed from the eye, or where, from the extraordinary ſize of the ſtructure, it hath not been practicable to give every member its due protection, recourſe hath been had to artifice in order to produce the deſired effect.

An Aſſemblage of Eſſential parts and Mouldings is termed a Profile; and on the choice, diſpoſition, and proportions of theſe, depends the beauty or deformity of the Profile.

The moſt perfect are ſuch as are compoſed of few Mouldings, varied both in form and ſize, fitly applied with regard to their uſes, and ſo diſpoſed that the ſtreight and curved ones ſucceed each other alternately. In every Profile there ſhould be a predominant member, to which all the others ought to be ſubſervient, and ſeem made either to ſupport, to fortify, or to ſhelter it from the injury of the weather; this predominant member ought always to be one of the eſſential ones: thus in a Cornice, the Corona is principal, the Cyma or Cavetto cover it, and the Modillions, Dentils, Ovolo, and Talon ſupport it.

When ornaments are employed to adorn the Mouldings, ſome of them ſhould be left plain, in order to form a proper repoſe: for, when all are enriched, the figure of the Profile is loſt.

Variety of enrichments muſt not be carried to an exceſs. In Architecture they are only acceſſories; and therefore they ſhould not be too ſtriking, nor capable of long detaining the attention from the main object. Thoſe of the Mouldings in particular ſhould be ſimple and uniform, and never compoſed of more than two different repreſentations upon each moulding; which ought to be cut equally deep, formed of the ſame number of parts, and nearly of the ſame dimenſions, in order to produce one even uninterrupted tint through the whole, that ſo the eye may not be too ſtrongly attracted by any particular part.

When Frizes, or other large Members are to be enriched, the Ornaments may be ſignificant, and ſerve to indicate the Uſe of the Building, or the Qualities and Actions of the Owner: but it is a fooliſh cuſtom to croud every part with Arms, Creſts, Cyphers, and Mottos: for the figures of theſe things are generally bad, and betrays an unbecoming vanity in the patron of the ſtructure.

When objects are near, and liable to cloſe inſpection, every part of the ornament ſhould be expreſſed, and well finiſhed; but when they are much exalted, the detail may be ſlightly touched, or entirely neglected; for it is ſufficient if the general form be diſtinct, and the principal maſſes ſtrongly marked. A few rough ſtrokes, from the hand of a ſkilful maſter, are much more effectual than the moſt elaborate finiſhings of an artleſs imitator.

OF THE ORDERS OF ARCHITECTURE IN GENERAL See PLATE VI.

AN Order conſiſts of two principal Members, the Column and the Entablature; each of which is compoſed of three principal Parts. Thoſe of the Column are the Baſe, the Shaft, and the Capital; and thoſe of the Entablature are the Architrave, the Frize, and the Cornice. All theſe are ſubdivided into many leſſer parts, whoſe number, form, and dimenſions characterize each order, and expreſs the degree of ſtrength, delicacy, richneſs, or ſimplicity peculiar to it.

Of the Five Orders, three are called Grecian; to wit, the Doric, the Ionic, and the Corinthian; and two Latin, the Tuſcan, and the Compoſite.

The ſimpleſt and moſt ſolid of all theſe is the Tuſcan. It is compoſed of few Parts, devoid of Ornaments, and of a Conſtruction ſo maſſive, that it ſeems capable of ſupporting the heavieſt burden; whence it is, by Sir H. Wotton, compared to a ſturdy labourer in homely apparel.

The Doric is next in ſtrength to the Tuſcan; and, being of a grave, robuſt, and maſculine aſpect, is by Scamozzi called the Herculean. As it is the moſt ancient of all the Orders, it retains more of the ſtructure of primitive huts than any of the reſt; having Triglyphs in its Frize to repreſent the ends of the Joiſts; and Mutules in its Cornice, to repreſent the Rafters; its column being likewiſe, in various Antiques, executed without a Baſe, in imitation of the trees uſed in the firſt buildings, without any Plinths to raiſe them above the ground.

The Ionic is of a more ſlender make than either of the abovementioned orders. Its appearance is ſimple, yet graceful and majeſtic; its ornaments are few, nor is there any thing exaggerated, or remarkably ſtriking, in any of its parts: ſo that it is not improperly compared to a ſedate matron, in decent rather than magnificent attire.

The Corinthian, ſays Sir H. Wotton, is a column laſciviouſly decked, like a wanton courtezan. Its proportions are extremely elegant. It is divided into a great variety of members, and enriched with a profuſion of ornaments. Scamozzi calls it the Virginal: and indeed it has all the delicacy in its make, with all the gaiety, gaudineſs and affectation in its dreſs, peculiar to young girls.

The Compoſite is, properly ſpeaking, only a ſpecies of the Corinthian; and therefore retains, in a great meaſure, the ſame character.

Columns, in the opinion of Scamozzi, ſhould not be leſs than ſeven of their diameters in height, nor more than ten; the former being a good proportion in the Tuſcan, and the latter in the Corinthian order. The practice of the ancients, in their beſt works, is conformable to this precept: for which reaſon, according to the doctrine of Vitruvius, the Tuſcan columns are ſeven diameters in height, the Doric eight, and the Ionic nine, (as Palladio and Vignola have done,) and the Corinthian and Compoſite ten; which laſt is a mean between the proportions obſerved in the Pantheon, and in the three columns, both which are accounted excellent models of the Corinthian order.

The height of the Entablature, in all the Orders, is made one quarter of the height of the column; which was the common practice of the ancients, who, in all ſorts of Entablatures, ſeldom exceeded or fell much ſhort of that meaſure.

Nevertheleſs Palladio, Scamozzi, Alberti, Barbaro, Cataneo, de L'Orme, and others of the Modern Architects, have made their Entablatures much leſs in the Ionic, Compoſite, and Corinthian Orders, than in the Tuſcan or Doric. This, on ſome occaſions, may be not only excuſable but highly commendable; particularly where the intercolumniations are large, (as in a ſecond or third Order,) or in private houſes, or inſide decorations, where lightneſs may be preferred to dignity, and where expence, and every impediment to the conveniency of the fabric, is carefully to be avoided: but to ſet entirely aſide a proportion, which ſeems to have had the general approbation of the Ancient Artiſts, is preſuming too far.

Of two manners uſed by Architects to determine the dimenſions of the mouldings, and the leſſer parts that compoſe an Order, is choſen the ſimpleſt, readieſt, and moſt accurate; which is by the Module, or ſemi-diameter of the Column, taken at the bottom of the Shaft, and divided into thirty Minutes.

Monſieur Blondel, in his book entitled *Reſolution des quatre principaux Problêmes d'Architecture*, teaches various manners of diminiſhing Columns; the beſt and ſimpleſt of which is by means of the inſtrument which Nicomedes invented to deſcribe the Firſt Conchoid: for this, being applied at the bottom of the Shaft, performs at one ſweep both the ſwelling and the diminution; giving ſuch a graceful form to the Column, that it is univerſally allowed to be the moſt perfect practice hitherto diſcovered. The Columns in the Pantheon, accounted the moſt beautiful among the Antiques, are made in this manner; as appears by the exact meaſures of one of them to be found in *Deſgodet's Antiquities of Rome*. See PLATE VI.

In the remains of Antiquity the quantity of the diminution is various; but ſeldom leſs than one eighth of the inferior diameter of the column, nor more than one ſixth of it. The laſt of theſe is by Vitruvius eſteemed the moſt perfect.

The intention being to give an exact idea of the Orders of the Ancients, are repreſented here under ſuch figures and proportions as appear to have been moſt in uſe in the eſteemed works of the Romans; who, in the opinion of Leo. Bap. Alberti, and other eminent writers, carried Architecture to its perfection. It muſt not however be imagined that the ſame general proportions will on all occaſions ſucceed. They are chiefly collected from the Temples and Public Structures of Antiquity, and may by us be employed in Churches, Palaces, and other Buildings of magnificence, where Majeſty, and Grandeur of manner may be extended to their utmoſt limits, and where, the whole body being generally large, the parts require an extraordinary degree of boldneſs, to make them diſtinctly perceptible from the proper point of view; but in leſs conſiderable edifices, and under various circumſtances other proportions may be preferable.

OF THE TUSCAN ORDER. See PLATE VI.

THERE are no remains of a regular Tuſcan Order among the Antiques: the doctrine of Vitruvius concerning it is obſcure: and the Profiles of Palladio, Scamozzi, Serlio, de l'Orme, and Vignola are all imperfect.

The Deſign here annexed is chiefly imitated from Vignola's, who in this Order hath been almoſt univerſally followed: even Inigo Jones, who was ſo cloſe an adherer to Palladio, having employed Vignola's Profile in York ſtairs, and others of his buildings; but as the Cornice appears far inferior to the reſt of the Compoſition, have not ſcrupled to reject it, and in its place ſubſtitute that of Scamozzi, with ſuch alterations as were evidently neceſſary to render it perfect. The Height of the Column is fourteen Modules, or ſeven Diameters, and that of the whole Entablature three and a half Modules: which being divided into ten equal parts, three of them are for the Height of the Architrave, three for the Frize, and the remaining four for the Cornice, the Capital is in Height one Module; the Baſe, including the lower Cincture of the Shaft, is alſo one Module. And the Shaft, with its upper Cincture and Aſtragal, twelve Modules.

Theſe are the general meaſures of the Order. As to the particular Dimenſions of the minuter parts, they may be collected from the Deſign, where the Heights and Projections are accurately marked; the latter being counted from perpendiculars raiſed at the extremities of the inferior and ſuperior Diameters of the Shaft: a method preferable to that of De Chambray and Deſgodetz, who count from the Axis of the Column; becauſe the relations between the Heights and Projections are more perceptible, and whenever a Cornice or Entablature is to be executed without a Column, which very frequently happens, it requires no additional labour, as the trouble of deducting from each dimenſions the ſemi-diameter of the Column is ſaved.

The Tuſcan Order admits of no Ornaments of any kind; on the contrary it is ſometimes cuſtomary to repreſent, on the Shaft of its Column, ruſtic Cinctures: as at the Pitti of Florence, the Luxembourg at Paris, York Stairs in London, and many other Buildings of note. This practice, however, though frequent, and to be found in the works of ſeveral celebrated Architects, is ſeldom excuſable, as it hides the natural figure of the Column, alters its proportions, and deſtroys the ſimplicity of the whole compoſition. There are few examples of theſe bandages in the remains of antiquity; and, in general, it will be adviſeable to avoid them in all large compoſitions; reſerving the ruſtic work for the intercolumniation, where it may be employed with great propriety, to produce an oppoſition, which will render the aſpect of the whole diſtinct and ſtriking. But in ſmaller works, whoſe parts are few, and therefore eaſily comprehended, they may be ſometimes tolerated. Le Clerc thinks they are proper for gates of Citadels and Priſons, whoſe entrance ſhould be dreadful; and they are likewiſe fit for gates of Gardens or Parks, Grottos, Fountains, and Baths, where elegance of form, and neatneſs of workmanſhip, would be out of character. De L'Orme, who was exceeding fond of theſe Cinctures, hath employed them in ſeveral parts of the Thuilleries, covered with arms, cyphers, and other enrichments. This is quite abſurd: for they can never be conſidered in any other light, than as parts which, to avoid expence and trouble, were left unfiniſhed. We likewiſe find, in different parts of the Louvre, vermiculated ruſtics of which the tracks repreſent flower de luces, and other regular figures: a practice more unnatural than the former; though Monſieur Daviler gravely tells us that it ſhould always be done with propriety, and expreſs a relation to the owner of the ſtructure; that is, the figures ſhould repreſent his Arms, Creſt, Mottos, Cyphers, &c.

The Tuſcan Order, carrying with it an idea of ſtrength and ruſtic ſimplicity, is very proper for rural uſes, and may be employed in Farm-houſes, Stables, Maneges, and Dog-kennels; Green-houſes, Grottos, Fountains, gates of Parks and Gardens; and, in general, in all places where magnificence is not required, and expence is to be avoided. Serlio recommends the uſe of it in Priſons, Arſenals, Treaſuries, Sea-ports, and gates of fortified places; and Le Clerc obſerves, that though the Tuſcan Order, as treated by Vitruvius Palladio, and ſome others, ought to be entirely rejected, yet according to the compoſition of Vignola, there is a beauty in its ſimplicity, which recommends it to eſteem, and entitles it to a place both in private and public buildings, even in Royal Palaces, to adorn the lower apartments, offices, ſtables, and other places that require ſtrength and ſimplicity, where richer and more delicate orders would be improper.

In conformity to the doctrine of Vitruvius, and to the almoſt general practice of all the moderns, have given to the Height of the Tuſcan Column ſeven Diameters, or fourteen Modules; a proportion which is very proper for rural or military works, where an appearance of extraordinary ſolidity is required: but in Town buildings, intended for civil purpoſes, or in interior decorations, the Height of the Column may be fourteen and a half, or even fifteen Modules, as Scamozzi makes it: which augmentation may be made in the Shaft, without changing any meaſures either in the Baſe or Capital: nor need the Entablature be altered; for, as it is compoſed of few parts, it will be ſufficiently bold, though its Height be a little leſs than one quarter of the Height of the Column.

OF THE DORIC ORDER. See Plate VI.

AS this Profile of Vignola's is compoſed in a greater ſtyle, and in a manner more characteriſtic of the Order, than any other, have made choice of it for a model; having, in the general form and proportions, adhered ſtrictly to the original; though in particular member I have not ſcrupled to vary, when obſervation taught they might be improved.

Perfect proportion in Architecture, if conſidered only with regard to the relations between the different objects in a compotion, and as far as it relates merely to the pleaſure of the ſight, ſeems to conſiſt in this, that thoſe parts, which are either principal or eſſential, ſhould be ſo contrived as to catch the eye ſucceſſively, from the moſt conſiderable to the leaſt, according to their degrees of importance in the compoſition, and impreſs their images on the mind before it is affected by any of the ſubſervient members; yet that theſe ſhould be ſo conditioned, as not to be entirely abſorbed by the former, but capable of raiſing diſtinct ideas likewiſe, and ſuch as may be adequate to the purpoſes for which theſe parts are deſigned. The different figures and ſituations of the parts may, in ſome degree, contribute toward this effect: for ſimple forms will operate more ſpeedily than thoſe that are complicated, and ſuch as project will be ſooner perceived than thoſe that are more retired. But dimenſion ſeems to be the predominant quality; or that which acts moſt powerfully on the ſenſe: and this can only be diſcovered by experience. When therefore any number of parts, arranged in a particular manner, and under particular proportions, excite, in the generality of judicious ſpectators, a pleaſing ſenſation, it will be prudent on every occaſion, where the ſame circumſtances ſubſiſt, to obſerve exactly the ſame proportions; notwithſtanding they may in themſelves appear irregular and unconnected.

It may perhaps be objected that the proportions here eſtabliſhed, though good on one occaſion, may on others be faulty. But this objection will be groundleſs, with regard to Capitals and Entablatures: their ſituation, with reſpect to the Order to which they belong, is conſtantly the ſame; and the point of view being more or leſs diſtant, according to the ſize or elevation of the Order, the apparent magnitudes of their parts will conſtantly bear, nearly, the ſame proportion to each other; even though they ſhould be exalted to a ſecond or third ſtory. With regard to Baſes, indeed, their being placed on Pedaſtals, or immediately on the ground, will occaſion ſome difference in their appearance; and when they are raiſed to a ſecond ſtory, their figure and apparent proportions will be conſiderably altered. Nevertheleſs, it doth not ſeem neceſſary to vary their dimenſions in either of theſe caſes: for in the former of the two the alteration would be trifling; and, in the latter, the object is ſo far removed from the eye, that the ſpectator is rather occupied in conſidering the general maſs, than in examining its particular parts, which, on account of their diſtance, are not diſtinctly perceptible.

The Height of the Doric Column, including its Capital and Baſe, is ſixteen Modules, and the Height of the Entablature four Modules; the latter of which being divided into eight parts, two of them are for the Architrave, three for the Frize, and three for the Cornice.

In moſt of the Antiques, the Doric Column is executed without a Baſe: Vitruvius likewiſe makes it without one; the Baſe, according to that Author, having been firſt employed in the Ionic Order, to imitate the Sandal, or covering of a woman's foot. Scamozzi blames this practice; and moſt of the Moderns have been of his opinion; the greateſt part of them having employed the Attic Baſe in this Order. Monſieur de Chambray, however, whoſe blind attachment to the Antique is, on many occaſions, too evident, argues vehemently againſt this practice; which, as the Order is formed upon the model of a ſtrong man, who is conſtantly repreſented bare-footed, is, according to him, very improper; and though the cuſtom of employing a Baſe, in contempt of all ancient authority, hath, by ſome unaccountable and falſe notion of beauty, prevailed, he doubts not but the pureſt eye, when apprized of this error, will eaſily be undeceived; and as what is merely plauſible will, when examined, appear to be falſe, ſo apparent beauties, when not founded in reaſon, will of courſe be deemed extravagant.

Le Clerc's remarks on this paſſage are very judicious; and, as they will ſerve to deſtroy a notion, which is too prevalent among us, ſhall, for the benefit of thoſe, who are unacquainted with the original, tranſlate the whole paſſage. "In the moſt ancient monuments of this Order, ſays he, the Columns are without Baſes; for which it is difficult to aſſign any ſatisfactory reaſon. Monſieur de Chambray, in his Parallel, is of the ſame opinion with Vitruvius, and maintains that the Doric Column, being compoſed upon the model of a naked, ſtrong, and muſcular man, reſembling a Hercules, ſhould have no Baſe; pretending that the Baſe to a Column is the ſame as a ſhoe to a man. But I muſt own I cannot conſider a Column without a Baſe, in comparing it to a man, but I am at the ſame time ſtruck with the idea of a perſon without feet rather than ſhoes: for which reaſon I am inclinable to believe, either, that the Architects of Antiquity had not yet thought of employing Baſes to their Columns or that they omitted them, in order to leave the pavement clear; the Angles and Projections of Baſes being ſtumbling blocks to paſſengers, and ſo much the more troubleſome, as the Architects of thoſe times frequently placed their Columns very near each other: ſo that had they been made with Baſes, the paſſages between them would have been extremely narrow and inconvenient: and it was doubtleſs for the ſame reaſon that Vitruvius made the Plinth of his Tuſcan Column round; that Order, according to his conſtruction, being particularly adapted to ſervile and commercial purpoſes, where conveniency is preferable to beauty. However this be, perſons of good taſte will grant, that a Baſe not only gives a graceful turn to the Column, but is likewiſe of real uſe; ſerving to keep it firm on its plan; and that if Columns without Baſes are now ſet aſide, it is a mark of the wiſdom of our Architects, rather than an indication of their being governed by prejudice, as ſome adorers of Antiquity would inſinuate."

In imitation of Palladio, and modern Architects except Vignola, the Attic Baſe in this Order is uſed: and it is the moſt beautiful of any, though for variety's ſake, when the Doric and Ionic Orders are employed together, the Baſe invented by Vignola, of which a Profile is annexed, may ſometimes be uſed: Bernini has uſed it in the Colonnades of St. Peter's, and it hath been ſucceſsfully applied in many other buildings.

The Ancients ſometimes made the Shaft of the Doric Column priſmatic, as appears by a paſſage in the fourth book of Vitruvius; and at other times they adorned it with a particular kind of ſhallow Flutings deſcribed from the centre of a ſquare, no interval or fillet being left between them; of which ſort there are now ſome Columns to be ſeen at the Temples of Peſto near Naples, and in the church of St. Peter in Catenis at Rome. The former of theſe manners hath not been imitated by any of the moderns: nor is the ſecond very frequent; Scamozzi blames it for its want of ſolidity, the projecting angles between the Flutings being eaſily broken, and very ſubject to moulder.

Vitruvius gives the Height of the Doric Capital one Module, and all the moderns, except Alberti, have followed his example. Nevertheleſs, as it is of the ſame kind with the Tuſcan, they ſhould both bear nearly the ſame proportion to the Heights of their reſpective Columns; and conſequently the Doric Capital ought to be more than one Module, and accordingly it is ſo both at the Coliſeum, and in the Theatre of Marcellus; being in the former of theſe buildings upwards of thirty-eight Minutes, and in the latter thirty-three Minutes.

The Height of the whole Capital thirty-two Minutes, and in the Form and Dimenſions of the particular members, have deviated but little from the profile of the Theatre of Marcellus. The Frize, or Neck, is enriched with Huſks and Roſes as in Palladio's Deſign, and as it has been executed by Sangallo at the Farneſe, and by Cigoli in the Cortile of the Strozzi at Florence, as well as in ſeveral buildings of note in this city. The Projection of theſe Huſks and Flowers muſt not exceed that of the upper Cincture of the Column.

The Architrave is one Module in Height, and compoſed only of one Faſcia and a Fillet, as at the Theatre of Marcellus: the Drops are conical, as they are in all the Antiques; and not pyramidal, as they are very improperly made by moſt of our Engliſh workmen.

The Frize and Cornice are each of them one Module and a half in Height: the Metope is enriched with a Bull's ſkull, adorned with a Garland of Beads; in imitation of thoſe on the temple of Jupiter Tonans, at the foot of the Capitol. In ſome antique fragments, and in a greater number of modern buildings, the metopes are alternately enriched with theſe ox-ſkulls, and pateras; but they may be filled with any other ornaments of good forms, and frequently with greater propriety. Thus, in military ſtructures, heads of Meduſa, or the Furies; thunderbolts, and other ſymbols of horror, may be introduced: likewiſe helmets, daggers, and garlands of laurel, or oak. But ſpears, ſwords, quivers, bows, cuiraſſes, ſhields, and the like, muſt be avoided; becauſe the real dimenſions of theſe things are too conſiderable to find admittance in ſuch ſmall compartments; and repreſentations in miniature always carry with them an idea of littleneſs. In Sacred Buildings, cherubs, chalices, and garlands of palm or olive, may be employed; likewiſe doves or other ſymbols of moral virtues; and in private houſes, creſts and badges of dignity, may ſometimes be ſuffered, though ſeldom; and indeed never, when they are of ſuch formal and inſipid figures, as ſtars and garters, crowns, coronets, mitres, truncheons, and the like; the bad effects of which may be ſeen at the treaſury in St. James's Park, and in many other places.

Too much variety in the ornaments of the Metopes muſt be avoided, for fear of deſtroying the unity of the compoſition: and it is beſt never to introduce more than two different repreſentations, which could not conſiſt of above one, or at moſt two objects, each, of ſimple forms, and not overcharged with ornaments. In the diſpoſition of theſe care muſt be taken to place them with Symmetry: thoſe on the right correſponding with thoſe on the left; wherefore, when a Triglyph happens to be in the middle of a Front, it becomes neceſſary to couple the middle ones, by filling the two Metopes, on each ſide of the central Triglyph, with the ſame ſort of ornaments; (as at the gate of Burlington-Houſe) diſpoſing the reſt alternately throughout the whole Front, as uſual. It is likewiſe to be obſerved, that the Ornaments of the Metopes are not to project ſo much as at Bow-Church, and at General Wade's Houſe in Burlington-Garden; where they are far more ſtriking than the Triglyphs, which ought to be predominant; being eſſential and principal parts in the compoſition. Palladio, in the Baſilica of Vicenza, has given to the moſt elevated parts of the Ox-Skulls and pateras very little more projection than that of the Triglyph, and in this he has copied the Ancients, who ſeldom or never gave more projection to any Ornament than that of the border in which it was encloſed; as appears by thoſe inimitable fragments in the Villa Medici, and many otherr in different parts of Rome. The Channels of the Triglyph in their Plan commonly form a right angle; but, to give them more effect, a narrow channel may be cut in the inner angle from top to bottom, and quite to the ſolid of the Frize.

In the Cornice we have deviated very little from the original. Le Clerc, who, in his Doric Profile, has imitated that of Vignola, makes the Mutules as broad as the Capital of the Triglyph. Mr. Gibbs hath followed his example; and they have been executed in this manner at a couple of doors to houſes on the North-Side of Lincoln's Inn Fields. But Vignola's method is preferable, who makes them only as broad as the Triglyph. The ornaments of the Soffit are nearly the ſame as thoſe of Vignola: they ſhould be entirely wrought in the ſolid of the Corona, and have no projection beyond it. There is no neceſſity for cutting them deep. In moſt of Palladio's buildings, they do not enter above two minutes, and that is ſufficient.

Of all the Orders the Doric is moſt difficult to diſtribute, on account of the large Intervals between the Triglyphs. At the Coliſeum they are omitted; and ſo they are in the Colonnades of St. Peter's, and in ſeveral other buildings at Rome. This indeed obviates the difficulty; but it likewiſe deprives the Order of one of its principal ornaments, without which it is very little preferable to the Tuſcan.

The Ancients employed the Doric in Temples dedicated to Minerva, to Mars, and to Hercules; whoſe grave and manly diſpoſitions ſuited well with the character of this Order. Serlio ſays it is proper for Churches dedicated to Jeſus Chriſt, St. Paul, St. Peter, or any other Saints remarkable for their fortitude, in expoſing their lives for the Chriſtian faith. Le Clerc recommends the uſe of it in all kinds of Military Structures; as Arſenals, Gates of fortified places, Guard-houſes, &c. and it may likewiſe be employed in the Houſes of Generals, or other Martial men, in Mauſoleums erected to their memory, or in Triumphal Bridges and Arches built to celebrate their victories.

The Height of the Doric Column here is ſixteen Modules; which, in buildings where Majeſty is required, is a good proportion: but in others it may be ſlenderer. Thus Vitruvius makes the Doric Column in Porticos higher by half a Diameter than in Temples; and moſt of the modern Architects have on ſome occaſions followed his example. In private houſes therefore it may be $16\frac{1}{3}$, $16\frac{1}{2}$, or $16\frac{2}{3}$ Modules high; and in interior decorations even ſeventeen Modules, and ſometimes a trifle more; which encreaſe in the Height may be made entirely on the Shaft, as in the Tuſcan Order, without changing either the Baſe or Capital. The Entablature may remain unaltered; for it will be ſufficiently high.

OF THE IONIC ORDER.

AMONG the Ancients, the form of the Ionic Profile appears to have been more poſitively determined, than that of any other order; for in all the Antiques at Rome (the Temple of Concord excepted) it is exactly the ſame, and agreeable to the decription Vitruvius hath given of it.

The modern Artiſts have likewiſe been unanimous in their opinion; all of them, excepting Palladio and his imitators, having employed the Dentil, Cornice, and the other parts of the Profile, nearly as they are found in the Coliſeum, the Temple of Fortune, and the Theatre of Marcellus.

Annexed to the Ionic Order there is a Deſign of the Antique Profile, collected from different Antiquities at Rome. The Height of the Column is eighteen Modules, and that of the Entablature four Modules and a half, or one quarter of the Height of the Column, as in the other Orders; which is a trifle leſs than in any of the regular Antique Ionics. The Baſe is Attic, as in all the Antiques, and the Shaft of the Column may be plain, or fluted with twenty-four Flutings, or twenty only, as at the Temple of Fortune; whoſe Plan may be a trifle more than a ſemi-circle, as at the Temple of Jupiter Tonans, and the Forum of Nerva, becauſe they then appear more diſtinct; and the Fillet, or Interval between them, muſt not be broader than one third of the breadth of a Fluting, nor narrower than one quarter thereof. The Ornaments of the Capital are to correſpond with the Flutings of the Shaft; and there muſt be an Ove above the middle of each Fluting. The Volutes are to be traced according to Goldman's method, which is the beſt.

The three parts of the Entablature bear the ſame proportion to each other, in this as in the Tuſcan Order. The Frize is plain, as being moſt ſuitable to the ſimplicity of the reſt; and the Cornice is almoſt an exact Copy from Vignola's Deſign, in which there is a grandeur of ſtile, that none of his competitors have arrived at.

In interior decorations, where much delicacy is required, the Height of the Entablature may be reduced even to one fifth of the Column, by obſerving the ſame method, and making the Module only four fifths of the ſemi-diameter.

As the Doric Order is particularly affected in buildings dedicated to male Saints, ſo the Ionic is uſed in ſuch as are erected to female Saints of the Matronal ſtate. It is likewiſe employed in Halls of Juſtice, in Libraries, Colleges, and other Structures, that have any relation to Arts or Letters, in private Houſes and in Palaces, to adorn the Women's Apartments, and, ſays Le Clerc, in all places conſecrated to peace and tranquility. The Ancients uſed it in Temples dedicated to Juno, to Bacchus, to Diana, and other Deities, whoſe diſpoſitions held a medium between the ſevere and effeminate.

OF THE COMPOSITE ORDER. Plate VI.

STRICTLY ſpeaking, the Ancients had but four Orders: the Compoſite was not conſidered by them as a diſtinct production. Vitruvius expreſsly tells us, Book IV. Chap. I. that on Corinthian Columns other Capitals of various kinds were employed; which nevertheleſs ought not to change the names of the columns, becauſe their proportions remained ſtill the ſame.

The Moderns, however, have ranked the Compoſite with the four orders mentioned by Vitruvius; having, among the great number of Capitals to be met with in the remains of antiquity, choſen for a model that which hath been uſed in the Triumphal Arches, in the Temple of Bacchus, and the Baths of Diocleſian; rather, as agreeing more with the deſcription of Vitruvius, (who obſerves that they were compoſed of the Ionic, Doric, and Corinthian) than from any preference in point of beauty to many others.

It doth not appear that the Ancients affected any particular form of Entablature to this Capital. Sometimes the Cornice is entirely plain, as in the Temple of Bacchus, at others, as in the Arch of Septimius Severus, it is enriched with Dentils, differing very little from the Ionic; and in the Arch of Titus there are both Dentils and Modillions; the whole form of the Profile being the ſame with the Corinthian, as executed in the Antiques at Rome.

The following is an extract from Sir William Chambers; therefore we ſhall uſe his own words:

" The Height of the Column is twenty Modules, and that of the Entablature five: the Baſe is Attic, and its meaſures the ſame as in the Doric and Ionic Orders; but as the Module is leſs, all its parts are of courſe more delicate. The Shaft is enriched with Flutings, which may be to the number of twenty, or twenty-four, as in the Ionic Order: for there is no reaſon why their number ſhould be augmented. The Module is leſs; the Flutings will therefore be leſs likewiſe, and correſpond exactly with the character of the reſt of the Compoſition.

" The Capital is of the ſame kind that all the Moderns have employed in this Order, and enriched with leaves of the Acanthus, as all the Antique Capitals of this ſort are. With regard to the method of tracing it, few directions will ſuffice: for the Deſigns are all exactly figured. The Curvatures of the Abacus are deſcribed from the ſummits of equilateral triangles; the projection of the Volutes is determined by a line drawn from the extremity of the Aſtragal to the extremity of a horn of the Abacus; and the projection of the Leaves is determined by another line drawn from the Fillet below the Aſtragal, parallel to the former.

" The manner of executing both theſe, and all other enriched Capitals, is, generally ſpeaking, bad. I do not, however, mean to accuſe our Engliſh workmen of wanting capacity: a great number of them are excellent, and, in neatneſs of execution, outdo, perhaps, thoſe of any other country whatever: but, from the parſimony of their employers, and, in ſome degree, for want of perfect ſkill and facility in deſigning, their performances are often flat, without intention or effect; in ſhort, to the laſt degree inſipid.

“ Many, even of our greateſt Architects, have too much neglected the detail; having employed their attention wholly on the general diſpoſition of their Compoſitions. This neglect, though authorized by great examples, ought by no means to be imitated: it is the buſineſs of the Architect to attend to the minuteſt object, as well as to the moſt conſiderable. If the entire execution of the fabric be left to his direction, the faults that are committed will be ſtated to his account: and therefore it will be prudent in him to chuſe good workmen, and to furniſh them with proper models, and preciſe inſtructions; in which he will ſhew the extent of his capacity, and diſtinguiſh himſelf from the common herd of thoſe who aſſume the title of Architects. The moſt maſterly diſpoſition, incorrectly executed, can only be conſidered as a ſketch in Painting, or as an excellent piece of Muſic performed by Country Fidlers.

“ The Foot of the Leaves of the Capital muſt not project beyond the upper part of the Shaft of the Column, as at St. Carlo in the Corſo at Rome, and at the Banqueting-Houſe in London; for nothing is uglier: neither is the lower row of them to bend forwards, as in many of the Antiques, and in ſome Modern Buildings, becauſe they then hide a great part of the upper Leaves, and give a diſagreeable form to the whole Capital. The different bunches that compoſe the Leaves muſt be ſtrongly marked, and maſſed in a diſtinct manner. The Sprigs, that ſpring from between the upper ones, are to be kept flat upon the Vaſe; and the Ornaments of the Volutes are not to project beyond the Fillets that encloſe them. Theſe are all the directions that can well be given in writing: but thoſe who would excel in works of this kind muſt conſult Nature, and thoſe Buildings, Ancient or Modern, in which they have been executed with care and judgment.

“ The parts of the Entablature bear the ſame proportion to each other, as in the Ionic and Tuſcan Orders. The Architrave is nearly the ſame with thoſe of Palladio, Vignola, and the Baſilica of Antoninus. The Frize is enriched with Foliages, in imitation of thoſe at Nero's Frontiſpiece; whoſe moſt prominent parts ought never to project beyond the uppermoſt Moulding of the Architrave.

“ The Cornice is imitated from Scammozzi, and differs from the Corinthian only in the Modillions, which are flat. The Soffit of the Intervals between the Dentils muſt be hollowed upwards, behind the little Fillet in Front, as they are in moſt of the Antiques; which occaſions a dark ſhade, that marks the Dentils more diſtinctly: and the ſame muſt be obſerved in the Ionic and Corinthian Orders. The Roſes in the Soffit of the Corona are not to project beyond its horizontal Surface; and care muſt be taken not to vary them ſo much as at St. Peter's of the Vatican, becauſe the Unity of the Compoſition ſuffers thereby. The Modillions or Dentils might with almoſt as much propriety be varied: it will be beſt therefore to make them all alike, as they are in moſt of the Antiques, and at Mr. Spencer's Houſe in the Green Park; that ſo they may not ſtrike the beholder as diſtinct objects, but as parts of one great whole. Or they may be of two kinds, which occaſions more variety, and no confuſion: for the ideas ſucceed each other ſo rapidly, that the third takes place before the firſt is in any degree obliterated; ſo that nearly the ſame effect is produced as by a continued ſucceſſion of the ſame object. But though this variety be allowable in ſmall objects, which the eye peruſes at a ſingle glance, and in ſuch as are merely acceſſory, and do not influence the general form of the Compoſition; yet it is by no means to be tolerated in Columns, and other large or eſſential parts, which, from the number of their conſtituent points, are not conveyed to the mind at once, either with eaſe or perfect clearneſs; and therefore, if varied, cannot fail of exciting confuſed ideas.

“ The Romans uſed the Compoſite Order more frequently in their Triumphal Arches than in any other Buildings; meaning, as Serlio ſuppoſes, to expreſs their dominion over thoſe nations that invented the Orders of which this is compoſed. It may, ſays Le Clerc, be uſed with propriety, wherever Elegance and Magnificence are to be aſſembled; but it is more particularly adapted for Buildings intended to commemorate any ſignal Event, or to celebrate the Virtues and Actions of Conquerors or Legiſlators: becauſe the Capitals, and other Ornaments, may be compoſed of Emblems and alluſive Repreſentations; which is agreeable to the cuſtom of the Ancients; as appears by multitudes of Fragments of Capitals, and other Members of Architecture, to be ſeen in different parts of Rome.

“ The Compoſite Entablature may be reduced to two ninths of the Column, (which, to avoid Fractions, I ſhall call four Modules and a half) by making the Module only nine tenths of the ſemidiameter, and obſerving the meaſures as in the Deſign; and there will be a Dentil in the outer Angle, as in the Ionic Order. It may likewiſe, if required, be reduced to one fifth, by making the Module four fifths of the ſemi-diameter: though, in caſes where it is neceſſary to diminiſh it ſo much, it will be beſt to employ the Ionic Cornice; which, being compoſed of fewer parts, will ſtill retain an air of grandeur, notwithſtanding the ſmallneſs of the whole maſs.

“ Moſt Authors give the laſt place to the Compoſite Order, as being the laſt invented, and a Compound, which of courſe ought to be preceded by all the Simples. I have followed wiih Scamozzi's method; his arrangement appearing to me the moſt natural: for his Orders ſucceed each other according to their degrees of ſtrength, and in the progreſſion that muſt abſolutely be obſerved whenever they are employed together.”

OF THE CORINTHIAN ORDER.

THE moſt perfect Model of the Corinthian Order, among the Antiques at Rome, is generally allowed, upon the whole, to be the three columns in the Campo Vaccino; the remains, as is thought, of the Temple of Jupiter Stator. Palladio in his fourth book, where he gives the Profile at large, acknowledges that he never had ſeen any work better executed, or more delicately finiſhed; that all its parts are beautifully formed, well proportioned, and artfully combined; which two laſt qualities are taken to be ſignified by his *Beniſſimo Inteſi.*

With theſe favourable ſentiments it is remarkable, that, in his deſign of the Corinthian Order, he hath ſo far deviated from this excellent original as ſcarcely to leave the ſmalleſt ſhadow of reſemblance to it.

The Column is twenty Modules high, and the Entablature five; which proportions are a medium between thoſe of the Pantheon and of the three Columns. The Baſe of the Column may either be Attic or Corinthian: they are both beautiful. Palladio and Scamozzi have employed the Attic Baſe, enriched with Aſtragals: but ſo frequent a repetition of the ſame form hath a bad effect, as may be ſeen at the Church of St. Martin's in the Fields, and at the Bank.

If the Entablature be enriched, the Shaft of the Column may be fluted: provided it be not compoſed of variegated Marble: for a diverſity of colours renders even ſmooth ſurfaces confuſed, and ornaments of Sculpture only ſerve to make the confuſion greater. The Flutings may be filled to one third of their height with Cablings, as in the inſide of the Pantheon; which will ſtrengthen the lower part of the Column, and make it leſs liable to injury. But if the Columns are not within reach, or ſubject to be hurt by Paſſengers, theſe are better omitted: for the general hue of the Column will then be more even. In ſome very rich Buildings, the Cablings are compoſed of Reeds, Ribands, Huſks, Flowers, &c. (at the Thuilleries in Paris there are ſome exquiſitely wrought by Jean Gougeon's own hand,) but it is better to reſerve ſuch niceties for interior decorations. In the exterior, whatever doth not contribute to the general effect of the whole building, is in a great meaſure uſeleſs, and an expence that might more judiciouſly be employed in places where it would be more attended to. In general, exceſſive ornaments, though they encreaſe the magnificence of a building, always deſtroy the grandeur of its effect. The parts that in themſelves are large, and ſo formed and diſpoſed as to receive broad maſſes and ſtrong impreſſions of light and ſhade, will of courſe excite great ideas: but if they are broken into a number of ſmall diviſions, and their ſurface ſo varied as to catch a thouſand impreſſions of light, demi-tint, and darkneſs, the whole will be confuſed, trifling, and incapable of cauſing any grand emotions.

The Capital is enriched with olive-leaves, as almoſt all the Antiques at Rome of this order are; the Acanthus being ſeldom employed but in the Compoſite. De Cordemoy, however, prefers the Acanthus; and obſerves that the flexible ſprigs, which accompany the leaves of that plant, may more naturally be ſuppoſed to form the Contour of the Volutes, than the ſtiff branches of a laurel or olive. It is ſtrange, ſays he, that people ſoon ceaſe to eſteem what is natural: nature and reaſon muſt always be violated, and we prefer a confuſed jumble of little pointed leaves of the olive or laurel, to the ſimple and graceful Contours of the Acanthus.

With regard to the manner of tracing and working the Capital, the deſigns, together with what hath been ſaid on the ſame head under the Compoſite order, will ſufficiently explain it.

The diviſions of the Entablature bear the ſame proportion to each other as in the Tuſcan, Ionic and Compoſite orders. The Frize is enriched with a Baſs Relief, compoſed from various fragments in the Villa Medici at Rome. The parts and ornaments of the Cornice are all regularly diſpoſed: the Coffers in the Soffit of the Corona are ſquare, and the borders round them alike on all ſides; as they are at the Arch of Titus, and as Palladio hath made them: a precaution which Vignola neglected.

The Corinthian Entablature may be reduced to two ninths, or one fifth of the Height of the Column, by the ſame rule as in the Ionic and Compoſite Orders. But when it is neceſſary to make it ſo ſmall as one fifth, it will be beſt to uſe the Ionic Entablature, as Palladio hath done in the Periſtyle of the Olympic Theatre at Vicenza, and in many others of his buildings; or to retrench the Dentils of the Cornice, as in Serlio's and Scamozzi's Profiles; the part of the Cornice under the Modillion-Band being compoſed only of the Ovolo and Oge ſeparated by a Fillet; as at the Temples of Trevi and of Sciſi in Umbria, mentioned by Palladio in his fourth Book.

The Corinthian order is proper for all buildings, where Delicacy, Gaiety, and Magnificence are required. The Ancients uſed it in Temples dedicated to Venus, Flora, Proſerpine, and Nymphs of the Fountains; becauſe the Flowers, Leaves, and Volutes, that adorned it, ſeemed well adapted to the Delicacy of theſe Deities. As it is the moſt Magnificent of all the Orders, it is extremely proper for Palaces, public Squares, and Churches dedicated to the Virgin Mary, or other Virgin Saints; and on account of its Gaiety it may likewiſe be uſed in Theatres, Banqueting-Rooms, and all Places conſecrated to Mirth and Pleaſure.

Several ſorts of leaves are applied to compoſe the capitals of the Corinthian and Compoſite columns, viz. the acanthus, parſley, olive, laurel, oak, &c. &c. Sketches of ſome of thoſe leaves appear in the plate of the Orders.

PILASTERS.

PILASTERS differ from columns only in their plan; which is a ſquare, as that of columns is round. Their baſes, capitals, and entablatures, have the ſame parts, with the ſame heights and projections, as thoſe of columns: and are alſo diſtinguiſhed by the ſame names.

The column is undoubtedly more perfect than the pilaſter. However they may be employed with great propriety on many occaſions. Some authors declaim againſt pilaſters, becauſe, according to them, they do not admit of diminution. But this is a miſtake; there are many inſtances, in the remains of antiquity, of their being diminiſhed. Scamozzi always gave his pilaſters the ſame diminution as his columns: Palladio and Inigo Jones have likewiſe diminiſhed them in many of their buildings.

Pilaſters are employed in churches, galleries, halls, and other interior decorations, to ſave room; for, as they ſeldom project beyond the ſolid wall above one quarter of their diameter, they do not occupy near ſo much ſpace as columns. They are likewiſe uſed in exterior decorations; ſometimes alone, inſtead of columns, on account of their being leſs expenſive; as in Bedford Square, &c. and ſometimes they accompany columns, being placed behind them to ſupport the architraves, where they enter the building.

The projection of pilaſters are various and muſt be ſuited to the ſtyle of the Architecture they are to accompany: they are frequently adorned with flutings, in the ſame manner as thoſe of columns; and ſometimes ſunk with a pannel to receive foliage, &c. at the Adelphi.

Attics very properly follow the pilaſters; being nothing more than ſquare piers and pedeſtals with their cornices. The place of Attics, therefore, is at the uppermoſt extremity of a building, to which they ſerve as a crown, or very properly make a finiſhing for the other orders, when they have been uſed in the ſtructure. The baſe, dye, and cornice, of which they are compoſed, may bear the ſame proportions to each other as thoſe of pedeſtals do; and the baſe and cornice may be compoſed of the ſame mouldings as thoſe pedeſtals.

PERSIANS, CARYATIDES, AND TERMINI.

BESIDES columns and pilaſters, it is ſometimes cuſtomary to employ repreſentations of the human figure, to ſupport entablatures in buildings. The male figures are called Perſians; and the female, Carians, or Caryatides.

The Perſians are ſo called from a victory gained over the Perſians by Pauſanias, who having brought home ſpoils and trophies to the Athenians, they fixed upon Perſian figures for thoſe which ſhould ſupport entablatures, and thus kept in mind that there were once Perſian ſlaves in Athens. To repreſent theſe conquered people in the loweſt ſtate poſſible, they loaded them with the heavieſt entablature, viz. that of the Doric order. In proceſs of time, however, other figures beſides thoſe of Perſians were introduced, and other entablatures put over them; but the name was ſtill retained.

The proper Caryatides are women dreſſed in long robes, after the Aſiatic manner; and the origin of the device was as follows. The Carians had been long at war with the Athenians; but being at length totally vanquiſhed, their wives were led away captives; and, to perpetuate the memory of this event, trophies were erected, in which figures of women dreſſed in the Caryatic manner, were uſed to ſupport entablatures like the Perſians; and though other female figures were afterwards uſed in the ſame manner, the name of Caryatides was always retained.

The ancients made frequent uſe of Perſians and Caryatides, and delighted in diverſifying them a variety of ways. The modern artiſts have followed their example; and there are a great many compoſitions of this kind to be met with in different parts of Europe.

Indecent attitudes, diſtorted features, and all monſtrous productions, ought to be avoided, of which there are various examples in Gothic buildings. On the contrary, the attitudes ſhould be ſimple and graceful, the countenance always pleaſing, though varied and ſtrongly marked agreeable to the nature of the object repreſented.

Termini are ſometimes employed, inſtead of Perſians or Caryatides, to ſupport the entablatures of monuments, chimney-pieces, and ſuch like compoſitions. Theſe figures owe their origin to the ſtones uſed by the ancients to mark the limits of particular poſſeſſions.

PEDESTALS.

MOST writers conſider the Pedeſtal as a neceſſary part of the order, without which it is not complete. It is indeed a matter of little importance whether it be conſidered in that light, or as a diſtinct compoſition: we ſhall therefore treat of a pedeſtal as a diſtinct body, having no more connection with the order than an attic, a baſement, or any other part with which it may on ſome occaſions be aſſociated.

A pedeſtal conſiſts of three principal parts; the baſe, the dye, and the cornice. The dye is always nearly of the ſame figure; being conſtantly either a cube or a parallelopipedon: but the baſe and cornice are varied and adorned with more or fewer mouldings, according to the ſimplicity or richneſs of the compoſition in which the pedeſtal is employed. Hence pedeſtals are, like columns, diſtinguiſhed by the names of *Tuſcan*, *Doric*, *Ionic*, *Corinthian*, and *Compoſite*.

With regard to the proportion that pedeſtals ought to bear to that of the columns they ſupport, it is by no means fixed. Both the ancients and moderns vary greatly on this head. Vignola's proportions are generally reckoned the beſt. He makes his pedeſtals in all the orders of the ſame height, viz. one third of the column; and as their breadth of courſe increaſes or diminiſhes in the ſame degree as the diameters of their reſpective columns do, the character of the order is always preſerved, which, according to any other method, is impoſſible.

As to the diviſions of the pedeſtals; if the whole height be divided into nine parts, one of them may be given to the height of the cornice, two to the baſe, and the ſix remaining to the dye. The breadth of the dye is always made equal to that of the plinth of the column. The projection of the cornice may be made equal to its height; and the baſe being divided into three parts, two of them will be for the height of the plinth, and one for the mouldings, whoſe projection muſt be leſs than that of the cornice.

INTERCOLUMNIATIONS.

COLUMNS are either engaged, or inſulated; and, when inſulated, are either very near the wall, or at a conſiderable diſtance from it. Engaged columns, or ſuch as are near the walls of a building, are not limited in their intercolumniations, as theſe depend on the breadths of the arches, windows, niches, or other decorations placed between the columns. But columns that are entirely detached, and perform alone the office of ſupporting the entablature, as in periſtyles, porches and galleries, muſt be near each other, for the ſake both of real and apparent ſolidity.

The intercolumniations among the ancients were various. Thoſe uſed in the Ionic and Corinthian orders were the pycnoſtyle, of which the interval was equal to one diameter and a half of the column; the ſyſtyle, whoſe interval was equal to two diameters; the euſtyle, to two and a quarter; the diaſtyle to three, and the aræoſtyle to four. In the Doric order, they uſed other intercolumniations, regulating them by the triglyphs, one of which was always placed directly over the middle of each column; ſo that they were either ſyſtyle, monotriglyph, of one diameter and a half; diaſtyle, of two diameters; and the Tuſcan intervals were very wide, ſome of them being above ſeven diameters, which was very practicable, as the architraves were of wood.

Sometimes, on account of the windows, doors, niches, and other decorations, which correſpond with the intercolumniations of the periſtyle, or gallery, it is not impoſſible to make the intervals ſo narrow as euſtyle, or even as diaſtyle: wherefore the moderns, authoriſed by ſome few examples of the ancients, where grouped columns are employed, have invented a manner of diſpoſing them, called by Perrault aræoſtyle, which admits of a larger interval, without any detriment to the apparent ſolidity of the building. This kind of diſpoſition is compoſed of two ſyſtyle intercolumniations; the column that ſeparates them being approached towards one of thoſe at the extremities, ſufficient room only being left between them for the projection of the capitals; ſo that the great ſpace is three diameters and a half wide, and the little one half a diameter.

In periſtyles, galleries, or porticos, all the intercolumniations muſt be equal; but in a loggia, or porch, the middle interval may be broader than the others, by a triglyph or modillion, or three or four dentils; unleſs the columns at the angles be coupled, or grouped with pilaſters; in which caſe, all the intervals ſhould be of the ſame dimenſions.

When buildings are very ſmall, as is frequently the caſe in temples and other inventions uſed for ornamenting gardens, the intercolumniations may be broader, in proportion to the diameter of the columns, than uſual; becauſe, when they are nearer each other than three feet, there is hardly room for a bulky perſon to paſs between them.

ARCHES.

ARCHES are not ſo magnificent as colonnades; but they are more ſolid and leſs expenſive. They are proper for triumphal entrances, gates of cities, of palaces, of gardens, and of parks, and in general for all openings that require an extraordinary breadth.

There are various manners of adorning arches. Sometimes their piers are ruſticated; ſometimes they are adorned with pilaſters, termini, or caryatides; and ſometimes they are made ſufficiently broad to admit niches or windows. The circular part of the arch is either ſurrounded with ruſtic key-ſtones, or with an archivolt enriched with mouldings; which in the middle, is ſometimes interrupted by a conſole, a maſk, ſerving at the ſame time as a key to the arch, and as a ſupport to the architrave of the order. The archivolt is ſometimes ſupported by an impoſt, at the head of the pier; and at others by columns placed on each ſide of it, with a regular entablature, or architrave and cornice. There are likewiſe inſtances of arcades without piers, the arches being turned on ſingle columns, as in the temple of Faunus at Rome, &c. This practice, however, ought to be ſeldom imitated, as it is neither ſolid nor handſome.

When arches are large, the key-ſtone ſhould never be omitted, but cut in the form of a conſole, and carried cloſe under the ſoffit of the architrave, which on account of its extraordinary length, requires a ſupport in the middle. The impoſts of arches ſhould never be omitted; at leaſt, if they be, a platform ought to ſupply their place. If columns are employed without pedeſtals in arcades, they ſhould always be raiſed on a plinth. In all arches, the circular part ought not to ſpring immediately from the impoſt, but take its riſe at ſuch a diſtance above it as is neceſſary in order to have the whole curve ſeen at the proper point of view.

The void or aperture of arches ſhould never be higher nor much lower, than double their breadth; the breadth of the pier ſhould ſeldom exceed two thirds, nor be leſs than one third, of the breadth of the arch; and the angular pier ought to be broader than the others, by one half, one third, or one fourth; the impoſt ſhould not be more than one ſeventh, nor leſs than one ninth of the aperture; and the archivolt muſt not be more than one eighth, leſs than one tenth of it. The breadth of the conſole muſt, at the bottom, be equal to that of the archivolt; and its ſides muſt be drawn from the centre of the arch; the length of it muſt not be leſs than one and a half of its ſmalleſt breadth, nor more than double. The thickneſs of the pier depends on the breadth of the portico; for it muſt be ſtrong enough to reſiſt the preſſure of its vault. But with regard to the beauty of the building, it ſhould not be leſs than one quarter of the breadth of the arch, nor more than one third.

The firſt Five Plates of this Syſtem give a general Idea of the Effect of Arches, agreeably to the beſt proportions. Several others, beſide the ſemicircular, are frequently employed; a ſegment of almoſt every portion under a ſemicircle, and alſo Eliptical Arches having three centers of variety of proportions, may be ſeen in many inſtances in the preſent new buildings, in and about this Metropolis.

ORDERS ABOVE ORDERS.

When, in a building, two or more Orders are employed, one above another, the laws of ſolidity require the ſtrongeſt ſhould be placed lowermoſt. Hence the Tuſcan muſt ſupport the Doric, the Doric the Ionic, the Ionic the Compoſite or Corinthian, and the Compoſite the Corinthian.

This rule, however, is not always ſtrictly adhered to. Moſt authors place the Compoſite above the Corinthian. There are likewiſe examples where the ſame order is repeated, as in the theatre of Statilus Taurus, and the Coliſeum; and others, where an intermediate order is omitted, and the Ionic placed on the Tuſcan, or the Corinthian on the Doric. But none of theſe practices ought to be imitated.

In placing columns above one another, the axis of all the columns ought to correſpond, or be in the ſame perpendicular line, at leaſt in front.

With regard to the proportions of columns placed above each other, Scamozzi's rule, That the lower diameter of the ſuperior column ſhould conſtantly be equal to the upper diameter of the inferior one, is univerſally eſteemed the beſt, and gives all the columns the appearance of one long tapering tree, cut into ſeveral pieces.

In Britain there are few examples of more than two ſtories of columns in the ſame aſpect; and though in Italy, and other parts of Europe, we frequently meet with three, and ſometimes more, yet it is a practice by no means to be imitated; for there is no poſſibility of avoiding many ſtriking inconſiſtencies, or of preſerving the character of each Order in its intercolumnial decorations.

BASEMENTS.

Instead of employing ſeveral Orders, one above the other, in a compoſition, the ground floor is ſometimes made in the form of a baſement, on which the order that decorates the principal ſtory is placed. The proportion of theſe baſements is not fixed, but depends on the nature of the rooms on the ground-floor. In the palace of the Porti in Vicenza, the height of the baſement is equal to that of the order. In ſome buildings, its height exceeds two thirds of that of the order; and, in others, only half the height of the order. It is not, however, adviſeable to make the baſement higher than the order it ſupports: neither ſhould it be lower than one half of the order.

PEDIMENTS.

Pediments, among the Romans, were uſed only as coverings to their ſacred buildings, till Cæſar obtained leave to cover his houſe with a pointed roof, after the manner of temples. In the remains of antiquity we meet with two kinds of pediments, the triangular and the circular. The former of theſe are promiſcuouſly applied to cover ſmall or large bodies: but the latter, being of a heavier figure, are never uſed but as coverings to doors, niches, windows, or gates.

As a pediment repreſents the roof, it ſhould never be employed but as a finiſhing to the whole compoſition.

The ancients, introduced but few pediments into their buildings, uſually contenting themſelves with a ſingle one to adorn the middle or principal part. But ſome of the moderns, and particularly the Italians, have been ſo immoderately fond of them, that they have introduced them profuſely.

The girder being a neceſſary part in the conſtruction of a roof, it is an impropriety to intermit the horizontal entablature of a pediment, by which it is repreſented, to make room for a niche, an arch, or a window.

In regular architecture, no other form of pediments can be admitted, beſides the triangular and circular. Both of them are beautiful, and when a conſiderable number of pediments are introduced, as when a range of windows are adorned with them, theſe two figures may be uſed alternately, as in the niches of the Pantheon, and in thoſe of the temple of Diana at Niſmes.

The proportion of pediments depends upon their ſize; for the ſame proportions will not do in all caſes.

When the baſe of the pediment is ſhort, its height muſt be increaſed; and when the pediment is long, the height muſt be diminiſhed. The beſt proportion for the height is from one ſixth to one fourth of the baſe, according to the extent of the pediment, and the character of the body it covers. The materials of the roof muſt alſo be attended to.

The tympan is always on a line with the front of the frize; and when large, admits of various ornaments.

BALLUSTRADES.

Ballustrades are ſometimes of real uſe in buildings; and at other times they are only ornamental. Such as are intended for uſe, as when they are employed in ſtair-caſes, before windows, or to incloſe terraſſes, &c. muſt always be nearly of the ſame height; never exceeding three feet and a half, nor much leſs than three. But thoſe that are principally deſigned for ornament, as when they finiſh a building, ſhould be proportioned to the architecture they accompany.

GATES, DOORS, AND PIERS.

There are two kinds of entrances, viz. Doors and Gates. The former ſerve only for the paſſage of perſons on foot; but the latter likewiſe admit horſemen and carriages. Doors are uſed as entrances to churches and other public buildings, to common dwelling-houſes and apartments: and gates ſerve for inlets to cities, fortreſſes, parks, gardens, palaces, &c. The apertures of gates being always wide, they are generally made in the form of an arch, that figure being the ſtrongeſt.

The general proportion for the apertures, both of the gates and doors, whether arched or ſquare, is, that the height be about double the breadth.

The moſt common, and indeed almoſt the only ornaments for gates are the piers by which they are ſupported, and which were originally no more than bare poſts into which the hinges of the gate were driven. Though this, however, is the only proper uſe of piers, it muſt be concealed as much as poſſible, and they muſt ſeem as if placed there only for ornament. As they are to be fixed to the wall before the houſe, ſo they muſt alſo be proportioned to it; and as they are to be ſeen in the ſame view with the front of the houſe, their correſpondence with it is equally neceſſary. They are to be placed on a plinth, and ſomething muſt be allowed by way of ornament and finiſhing at the top. All the luxuriance of fancy may be employed in the decoration of piers: but it will be proper to obſerve this general rule, that the pier being an inferior building, it muſt never be richer than the front of the houſe. If, for inſtance, the front of the houſe is ornamented with columns of the Doric order, the Ionic muſt not be uſed in the piers; and it will be found better to omit columns altogether, than to make uſe of the Tuſcan order for piers in any caſe. If the Ionic or Corinthian orders are employed in the front of the houſe, the Doric or Ionic may be uſed with propriety in the piers. One piece of ornament is almoſt univerſal in piers, namely, a niche with its ſeat, made as if for the conveniency of weary travellers. On this account, it will be proper to raiſe the columns on pedeſtals, becauſe the continued moulding from their cap will be a good ornament under the niche. The baſe of the columns ought always to be the Attic.

Inſide-doors, however ſmall the building may be, ſhould never be narrower than two feet nine inches; nor ſhould they ever, in private houſes, exceed three feet ſix inches in breadth, which is more than ſufficient to admit the bulkieſt perſon. Their height ſhould at leaſt be ſix feet three or four inches; otherwiſe a tall perſon cannot paſs without ſtooping. In churches, palaces, &c. where there is a conſtant ingreſs and egreſs of people, the apertures muſt be larger. The ſmalleſt breadth that can be given to a gate is 8½ or 9 feet, which is but juſt ſufficient for the paſſage of a coach.

WINDOWS.

THE firſt conſideration with regard to windows, is their ſize which varies according to the climate, the deſtination of the building, &c. In Britain, the windows of the ſmalleſt private houſes are commonly from 3 to 3½ feet broad; and being generally twice their breadth in height, or ſomewhat more, in the principal apartments, they generally riſe to within a foot or two of the cielings of the rooms, which are frequently no higher than 10 feet, and at moſt 12 or 13. But, in more conſiderable houſes, the apartments are from 15 to 20 feet high, and ſometimes more; and in theſe the windows are from 4 to 5, and 5½ feet broad, and high in proportion.

Theſe dimenſions are ſufficient for dwelling-houſes of any ſize in this country; when they are larger, they admit too much of the cold air in winter. But churches, and other buildings of that kind, may have larger windows, proportioned to the ſize of the ſtructures.

The proportions of the apertures of windows, depend upon their ſituation. Their breadth in all the ſtories muſt be the ſame; but the different heights of the apartments make it neceſſary to vary the height of the windows likewiſe. In the principal floor, it may be from $2\frac{1}{8}$ of the breadth to $2\frac{1}{3}$, according as the rooms have more or leſs elevation. In the ground ſtory, where the apartments are lower, the apertures of the windows ſeldom exceed a double ſquare; and, when they are in a ruſtic baſement, they are frequently made much lower. The height of the windows of the ſecond floor may be from 1½ of their breadth to $\frac{4}{5}$; and Attics and Mezzanines may be either a perfect ſquare, or ſomewhat lower.

The windows of the principal floor are generally moſt enriched. The ſimpleſt method of adorning them is, with an architrave ſurrounding the aperture, and ſometimes crowned with a frize and cornice level, or with a pediment.

DESIGN AND EXECUTION.

Design is divided into three heads, viz. the Plan or Ichnography; the Elevation, or Orthography; and the Section or Internal Scenography. To theſe belong extenſive, artful, and fertile *Invention:* true Taſte for beautiful forms and harmonious proportion: alſo ſound geometrical and philoſophical Judgment.

INVENTION.

Invention is indiſputably neceſſary to the purpoſe of deſign, whether for public or private uſe; the arrangement of rooms or apartments for oratory, ſtate, public buſineſs, routs, viſitors, retiring, eating, reading, ſtudy, dreſſing, living, ſleeping, and other purpoſes, together with their appendages and inferior offices of all denominations required to be annexed thereto, whether of a public or private nature, connection; convenience and good arrangement, are the great eſſentials.

TASTE.

Taſte for conſtructing and introducing of forms that pleaſe and facinate the beholder, with regard to the Plan, Elevation, Section, Convenience and beautiful Proportions.

As to the Plan: the arrangement, proportion, and decoration of rooms for the purpoſes they are intended ſeparately; and connected, reſpectively.

As to the Elevation, Character ſuitable to the purpoſe the building is intended for; Correctneſs in the ſtyle of Architecture made choice of; Harmony in the whole maſs of building; and beautiful proportional forms of the conſtituent parts of which it is compoſed; if to advance, or recede, to be well connected; in which much optical knowledge muſt be obſerved.

JUDGMENT.

Judgment, geometrical and philoſophical; the geometrical conſiſts in conſtructing the building upon true principles, that the architect may form his deſign, ſo as it may be put into execution with firmneſs and durable materials, and that the artiſt conſtructs with ſuch that are attainable. The Philoſophical conſiſts in the knowledge of the quality of materials of all kinds, and to judge what are moſt proper for the intended purpoſe, and of foundations natural and artificial; alſo earths, waters, metals, timber, &c.

The Executive part of Architecture may be divided under two heads; the Foundation and Structure.

A foundation is the bottom on which the ſtructure is to be raiſed, and may be natural or artificial.

A natural foundation is ſuch as require no artificial aſſiſtance, as ſtone, gravel, hard clay, ſand or earth, that hath been undiſturbed, called maiden; and ſuch as is ſufficient to receive and bear the intended ſtructure; to attain the knowledge of which, it is not only neceſſary to ſee the ſurface, if the building be maſſy; but to be acquainted with the ſtrata to a conſiderable depth; for which purpoſe the digging of a well is recommended, and the boreing with a worm borer in ſeveral parts of the foundation, to be ſatisfied the whole is of the ſame or a ſimilar texture; this is an eſſential point, and in which the philoſophical and experimental judgment of the architect muſt be carefully exerciſed.

An Artificial foundation is ſuch as when the earth cannot be ſunk ſufficiently low to come at a permanent natural one, without an increaſed or enormous expence; it then becomes neceſſary to invent an artificial one: if the bottom ſhould be looſe earth, rubbiſh, bog, or quagmire, the driving of Piles becomes requiſite; they ſhould be ſhod with iron, and drove to a depth till they reſiſt the engine or inſtrument with which they are driven, or are ſufficiently firm, and in quantity and proportion as the bottom may require, and the ſtructure weighty. The tops muſt be cut off perfectly level and morticed, and a grating of timber framed thereon; the cavities filled with brick or ſome hard material, and the whole planked (green timber is preferable). If the foundation ſhould be leſs uncertain, and the building not too weighty, tranſverſe pieces of timber, called ſleepers, laid at convenient diſtances, extending longer than the firſt courſes of brick or ſtone are wide; and planks laid thereon, may anſwer the purpoſe; and at all events buildings of magnitude, or great weight, ſhould be ſecured by turning reverſe arches under all the openings; and if the voids are large, the material ſhould be ſtone, if not, brick will do, as thoſe arches, if a ſegment of a circle require a longer radius; therefore ſtone is better bond, and which, if not ſo ſecured, fiſſures and ſettlements in the upper arches, and other parts of the building, are frequently the conſequence. See Plate VIII.

STRUCTURE.

THE Structure is any kind of building, erected upon the foundation, and is generally compoſed of timber, brick, or ſtone, or thoſe materials united. The various branches that compoſe the ſame, I ſhall divide under their different heads, all which it is the province of the Architect to underſtand perfectly, as to the quality and quantity of materials, the preferable way of diſpoſing and uniting them, and the value of the various articles and labour requiſite thereto.

The carpenters or timber work comprehends all the framing of the ſtructure, ſuch as the preparing to make a ſecure artificial foundation; the bond timbers, which ſhould always be halved and dovetailed at all the angles of the building, and the croſs walls thereof and the joinings ſcarfed; the lintels laying over all the voids, or doors, windows, &c. Wood, bricks, worked in the walls, where it is found neceſſary to fix wood dreſſings in the finiſhing, as grounds, architraves, &c. The naked floors, which are of three different ſorts, as expreſſed in Plate VIII.

Obſerve, to lay the ends of all girders, or principal timbers, on piers or poſts of partitions, and avoid placing them over openings, or any timbers, near chimney flues; and when flues do interfere, to frame trimming joiſts, as to the front of a chimney, or to the well hole of a ſtair-caſe.

The carcaſe-framing in timber buildings, partitions, ceilings, floors, raiſing plates, roofs, &c. &c. ſome ſpecimens of each, with their deſcriptive technical terms, are in the ſame plate, together with the proper pitches for the ſeveral coverings of buildings now in uſe.

The various finiſhings of wood-work within and about the ſtructure, is called the joiner's work, all which is uſually done in this country, with deal imported from Norway, Sweden, and Ruſſia; the quality and ſeaſoning of which are the principal eſſentials, and are employed in floors, doors, columns, architraves, chimney-pieces, moldings, dados, wainſcotings, linings, partitions, porticos, &c. as the ſkill of the Architect ſhall direct. Sometimes the floors, doors, ſaſhes, &c. are executed in wainſcot; and ſometimes the doors and ſaſhes are of mahogany; and when ſo, thoſe materials ſhould each be of the very beſt quality. The floors, doors, and other finiſhings, are of various qualities, both as to materials and labour, and are performed in a variety of ways, the expence governing the mode, and ſhould be appropriated with that judgment in the various buildings and apartments as they ſeverally deſerve, particularly obſerving, that white deal never be uſed without doors; it is a cheaper article, and is moſt proper for bedchamber floors and pannelling, being leſs liable to ſhrink than yellow; the yellow is conſiderably harder, and ſaturated with turpentine, therefore more fit to endure uſe and weather.

The brickwork is the next within our conſideration; moſt writers on that ſubject have preſcribed certain rules for depths under ground, and alſo thickneſſes; which rules no longer exiſt, as it is uſual to ſink till you meet with a firm foundation, and even in ſome inſtances, office buildings and ſmall houſes are erected on the ſurface of the ground; and when they are ſunk for offices under ground, if the bottom is firm, ſix or eight courſes of brick work is ſunk below the floor thereof: a ſection of each wall, agreeably to the Act of Parliament, is given in Plate VIII. which will ſerve to ſhow the preſent practice without further explanation, obſerving to make voids over voids, and ſolids over ſolids, to make all chimney flues with eaſy ſweeps, and free from ſudden checks; and that the brickwork be worked proper bond, perfectly level, and a cloſe joint with mortar made of quick lime, and drift ſand well incorporated; and to work reverſe arches, under openings, as doors and windows, &c. with arches over the ſame, notwithſtanding the lintells, as beforementioned, as that practice was much uſed by the ancients, which may be ſeen in many of their ruins where the timber is totally decayed. Alſo particular attention muſt be had to ſufficient drains and ſewers, to convey away the waſte water, ſoil, &c. and that ſtink traps be placed therein to prevent nauſeous ſmells. When maſonry is to be uſed with brickwork, the beſt way, if poſſible, is to leave the brickwork in ſuch a manner that the ſtone may be inſerted afterwards; but when that cannot be done, bond-ſtones muſt be introduced in the wall with the brickwork, and the whole worked with leiſure, the joints very cloſe, and the mortar tough; as the number of joints in proportion to the ſtone will ſettle ſomething, which deſtroy the union of the ſtone and brick; particularly in aſhler fronts, the bond and fabrick having been frequently ruined by not paying a proper atttention to the management thereof. The quality of ſtone ſhould particularly engage the attention of the architect, as it frequently happens that it is impregnated with ſalts, or are from too near the earthly bed of the quarry, or a ſoft ſtrata; in either caſe, very little time will make it ſcale and mutilate, which is a mortifying circumſtance after ſuch extra expence and labour. The ſtone work of Somerſet place is an example of excellent maſonry, particularly facing the Strand. Of coverings to houſes, ſlate is by much the moſt preferable, which is executed a variety of ways, and the qualities of ſlate are ſeveral. The Weſtmoreland is conſidered the ſtrongeſt and beſt. A patent for ſlating in a ſingular manner has lately expired, and is much practiced by Mr. Wyatt, and for ſome reaſons may be preferred, as it will admit the pitch of the roof to be conſiderably leſs than any other material, except lead or copper, and is a very reaſonable covering conſidering it does not require the roof to be boarded; but when it is uſed, care muſt be taken to admit ſufficient circulation of air into the roof, or it will be liable to decay.

In London it becomes neceſſary to have lead or copper gutters, with a parapet wall or ſtone blocking, and the water conveyed down by pipes; but in the country, dripping eves, in elevated ſituations, are to be preferred, as the autumnal ſeaſon ſo frequently ſtop the gutters and pipes, together with ſnow, &c. that capital houſes frequently ſuffer very much by the overflowing, unleſs they are ſingularly conſtructed, that the water may eſcape before it is poſſible to find its way within the building, as deſcribed in Plate VIII.

The external walls, with inſide, ſhould be battened for the plaiſtering, unleſs the walls are very thick, or the bricks hard and not abſorbent; care ſhould be taken that the ſand uſed for the purpoſe is not ſalt, drift ſand is the beſt and ſhould be uſed ſoon after it is made, or the lime will otherwiſe deſtroy the hair; floated plaiſtering is always to be preferred, although attended with rather more expence. Plaiſter ceilings made ornamental, and ſome rooms ſtuccoed and pannelled, the cornices enriched, and other ornaments introduced as medallions, tablets, &c. when done with judgment, and in a good ſtyle, and exquiſite workmanſhip, are very proper finiſhings for bettermoſt rooms. External plaiſtering very ſeldom ſtand the weather, as it is rare any compoſition hitherto invented anſwer the purpoſe; one great reaſon is, that when attempted, ſufficient care is not taken to prevent the wet getting into the brickwork at the back of the plaiſter coat; it is evident, that plaiſtering of good ſtone lime and clean drift ſand, in proper proportions and carefully worked, will ſtand, if the walls are battened and lathed, which certainly will endure as long as the timber and lath, on which it is worked, which many inſtances in very old towns and cities in England teſtify. Many attempts have been made to introduce materials to anſwer the purpoſe of lead or copper for gutters, but none have yet had the deſired effect; caſt lead is moſt preferable, and that not too thin; nor ſhould the joints be ever ſoldered, as in either caſe the effect of weather will crack that material, and cauſe drips, which is afterward an everlaſting expence.

The glazing may be done a variety of ways; cottages and inferior tenements with common glaſs in lead; the better ſort with Newcaſtle crown in ſaſhes; and the beſt wainſcot, mahogany, or metal ſaſhes, glazed with London crown or plate glaſs; in elegant rooms the latter is to be preferred, as objects ſeen from within are rendered more perfect in their appearance, and that glaſs does not eaſily admit objects to be ſeen in the rooms from without.

The article of painting is very eſſential to the preſervation of timber and iron-work, and equally ſo with reſpect to ornament; ſtucco'd walls are rendered very light and elegant by painting; and the ſcene will admit of change whenever the rooms require freſh painting; colours diſpoſed of with harmonizing taſte in a houſe, are a very great ornament; even plainneſs, in other reſpects, is much ſet off and enlivened by painting; but without ſide all timber and iron-work require it for its preſervation; ſo much ſo, that it ſhould be made a conſideration in all building and repairing leaſes granted for long terms, that the tenant do paint every ſeven years, twice at leaſt, in oil, as the caſe may require, particularly in ſouth and ſouth-weſt aſpects; external dreſſings, as architraves, frontiſpieces, and cornices of wood, have a very good effect if ſanded upon the laſt coat of paint, which not only gives the appearance of ſtone, but adds to its durability.

It very frequently happens, that the Architect is conſulted in the furniture of houſes; and, if a man of taſte, he is certainly moſt proper to give deſigns to furniſh the principal ſuite of apartments, as he will take care to harmonize all the parts, making together one general uniſon in the ſtyle with the whole; the contrary is ſometimes ſeen, as in a houſe in Portman Square, where you are conveyed through a ſuite of rooms, in the Grecian, French, Etruſcan, and Indian taſte; which mixture of ſcenes have an odd effect on the viſitor, not unlike enchantment, at leaſt I judge from experience.

Bridge Building is an art of great latitude, particularly where they extend over large and rapid rivers; and are in general built with timber, ſtone, or brick; of timber bridges none is found by experience ſo capable of being kept in repair as the moſt ſimple conſtruction; viz. that of a ſcaffold, ſuch as Putney Bridge, becauſe any timber contained therein can be eaſily removed, when decayed, and others ſupplied; for inſtance, if framed on a geometrical conſtruction, as Kew Bridge, Walton Bridge, and the like; the neceſſary mortices and tenons, being expoſed to the weather, ſoon decay, and cannot eaſily be replaced; it ſometimes happens that it is neceſſary the bridge ſhould be conſtructed of timber, as draw-bridges, and the like; one of which, of a forty feet opening, has been lately built from a deſign of my own at Newhaven, in Suſſex. There is a bridge of a very extraordinary nature at Schaffhauſen, in Switzerland, forming two arches of an almoſt incredible ſpan. Stone Bridges, of conſequence, have lately made great advances in England; no leſs than eight having been built acroſs the river Thames within a very few years; and many other very capital ones over other rapid rivers; and, from the experience in that art, the Engliſh are arrived at great perfection; not only of wood and ſtone bridges, we boaſt of one lately built of caſt-iron; at Colebrooke Dale, in Shropſhire; but, for the more extraordinary conſtruction of ſtone bridges, France, by the advantage of immenſe ſtone, have gone greater lengths in geometrical ſchemes than we are able to do with our materials; the Pont Nuelly contains five arches of 120 French feet each, and is perfectly level from end to end; and ſome other bridges, of ſingle arches, of an enormous ſpan; the abutments being properly ſecured, the ſingularity of the arch, and the long radius of the ſtone, are the principles of the conſtruction.

Within the laſt thirty years Architecture has been making gradual advances to excellence; and, with a degree of triumph, is poſſeſſing herſelf of Great Britain for her throne, and there to erect her ſtandard; and, if induſtry and perſeverance have a claim, the capital is certainly deſerving of ſo noble and honourable a gueſt.

The Seminaries therein, for the improvement of deſign, are truly worthy of applauſe, and to which moſt of our living artiſts owe much of their ſkill; particularly the Society of Arts, Manufactures, and Commerce, whoſe firſt exhibition was in 1760; the Incorporated Society of Artiſts of Great Britain, by Royal Charter, inſtituted 26 January, 1765; the Royal Academy, at Somerſet Place, under the immediate patronage of the King, where honorary premiums for deſign in Architecture are given; candidates ſent to Rome to compleat their ſtudies, free of expence; a courſe of lectures, elucidated by drawings of that ingenious artiſt, Thomas Sandby, Eſq; the profeſſor; and an annual public exhibition of the works of various artiſts; (by which means, it is preſumed, the expences are ſupported, as there is no known fund for the purpoſe;) together with the valuable publications of Palladio, Inigo Jones; the Ruins of Palmyra and Balbec, by Wood; the Ruins of Athens, by Stewart; Spalatro, the Diocleſian Palace, by Robert Adams; the Ionian Antiquities, collected by Parrs, for the Deletanti Society; the Ruins of Pœſtum; and many foreign publications imported; all which, artiſts of the preſent day ſeize with avidity for their improvement; which certainly is a means of eſtabliſhing in them true principles, and correct taſte; together with the ſuperior advantages of the experimental knowledge of the art by public buildings, new ſquares, ſtreets, bridges, &c. carrying on in and about the metropolis, with ſo much judgment and alacrity; all which cannot fail to render England the firſt ſchool of Architectural Study in the known world.

We have only to lament, that the materials of this country are inferior to thoſe where the art has been formerly carried to ſo great a degree of excellence; or, I doubt not, but the artiſts and workmen of this capital, are equal in taſte and abilities to the ancients. The tide and folly of reſtleſs faſhion are ſometimes rather too apt to warp them from their better judgment; which may be eaſily accounted for, as their employers whims frequently require to be gratified; but, when abſurd, ſhould be got the better of, if poſſible, as all improprieties are placed to the account of the artiſt, whoſe reputation muſt ſuffer in the judgment of the public.

The Six firſt Plates to elucidate the foregoing Syſtem, are ſelected from various works. The two latter I have deſigned, and ſhall engrave; they are meant to illuſtrate the Principles of Executive Deſigns, Hiſtorical Circumſtances, and Periods of the different Stages of Architecture in this Country, which, I truſt, will exhibit great Novelty, and will be found both uſeful and entertaining.

CHURCH-STREET, PADDINGTON. *JOHN PLAW.*

Military Architecture, or Fortification. See the latter Syſtem.

Naval Architecture. See the Art of Ship Building.

ARCHITHALASSUS, a ſynonyme of that curious ſhell called the Admiral-ſhell.

ARCHITRAVE, in architecture, that part of a column which lies immediately upon the capital, being the loweſt member of the entablature. Over a chimney, this member is called the mantle-piece; and over doors or windows, the hyperthyron.

ARCHITRICLINUS, in antiquity, the maſter or director of a feaſt, charged with the order and œconomy of it, the covering and uncovering of the tables, the command of the ſervants, and the like.

ARCHIVAULT, in architecture, implies the inner center of an arch, adorned with mouldings running over the faces of the arch-ſtones, and bearing upon the impoſts. It has only a ſingle face in the Tuſcan order, two faces crowned in the Doric and Ionic, and the ſame mouldings as the architrave in the Corinthian and Compoſite.

ARCHIVE, or Archives, a chamber or apartment wherein the records, charters, and other papers and evidences, of a ſtate, houſe, or community, are preſerved, to be conſulted occaſionally. Thus we ſay, the archives of a college, of a monaſtery, &c. The archives of antient Rome were in the temple of Saturn; the archives of the court of Chancery in England are in the Roll's-office.

ARCHMARSHAL, in the Germanic polity, denotes the grand marſhal of the empire, a dignity belonging to the elector of Saxony.

ARCHON, a term applied by ſome authors to divers officers, both civil and religious, under the Eaſtern or Greek empire. Thus biſhops are ſometimes called *archontes*; and the ſame may be ſaid of the lords of the emperor's court. We alſo read of the *archon of the antimenſia, archon of archons, grand archon, archon of churches, archon of the goſpel, archon of the walls, &c.*

ARCHPRIEST, Archpresbyter, in church government, ſignifies a prieſt or preſbyter eſtabliſhed in ſome dioceſe, with a pre-eminence over the reſt.

There are archpreſbyters ſtill ſubſiſting in the Greek church, who are veſted with moſt of the functions and privileges of chorepiſcopi or rural deans.

ARCHTREASURER, is a name given to the great treaſurer of the German empire.

This office was created with the eighth electorate, in favour of the elector Palatine, who had loſt his former electorate, which was given to the duke of Bavaria, by the emperor Ferdinand II. who took it away from Frederic V. elector Palatine, after the battle of Prague, where he was defeated in maintaining his election to the crown of Bohemia.

The dignity of archtreaſurer was conteſted between the elector of Brunſwick, who claimed it in virtue of his deſcent from the elector of Frederic and the elector Palatine.

ARCHILUTE, Arcileuto, in muſic, is a large lute, having its baſs ſtrings lengthened after the manner of the theorbo, and each row doubled, either with a little octave or an uniſon. It is uſed by the Italians for playing a thorough baſs.

ARCTIC, in aſtronomy, is an epithet given to the north pole.

It is called the *arctic pole*, on account of the conſtellation of the little bear, in Greek called αρκτος; the laſt ſtar in the tail of which nearly points out the north pole.

Arctic *Circle* is a leſſer circle of the ſphere, parallel to the equator, and 23° 30′ diſtant from the north pole; from whence its name. This, and its oppoſite, the antarctic, are called the two polar circles; and may be conceived to be deſcribed by the motion of the poles of the ecliptic, round the poles of the equator.

ARCTIUM, Burdock, in botany, is a genus of the polygamia æqualis order, belonging to the ſyngeneſia claſs of plants; and in the natural method ranking under the 49th order, Compoſitæ Capitatæ.

The calyx is globular; with ſcales having hooks reflected at the tops.

There are three ſpecies, viz. the lappa or common burdock, the tomentoſum, and the perſonata.

The tender ſtems of the common kind, deprived of the bark, may be boiled and eat like aſparagus. When raw, they are good with oil and vinegar.

The ſeeds, which have a bitteriſh ſubacrid taſte, are recommended as very efficacious diuretics, given either in the form of emulſion, or in powder to the quantity of a dram.

The roots, which taſte ſweetiſh, with a ſlight auſterity and bitteriſhneſs, are eſteemed aperient, diuretic, and ſudorific; and ſaid to act without irritation, ſo as to be ſafely ventured upon in acute diſorders.

ARCTOPHYLAX, (from αρκτος, *bear*, and Φυλαττω, *I guard*,) in aſtronomy, a conſtellation, called *Bootes*.

ARCTOPUS, in botany, is a genus of the polygamia diœcia claſs; and in the natural method ranking under the 45th order, Umbellatæ. The umbella of the male is compound; the involucrum conſiſts of five leaves; the corolla has five petals; the ſtamina are five; and two piſtilli: the umbella of the hermaphrodite is ſimple; the involucrum is divided into four parts, is ſpinous, large, and contains many male flowers in the diſk. There is but one ſpecies of arctopus, viz. the echinatus, a native of Ethiopia.

ARCTOTIS, in botany, is a genus of the polygamia neceſſaria order, belonging to the ſyngeneſia claſs of plants; and in the natural method ranking under the 49th order, Compoſitæ-diſcoides. The receptacle is briſtly; the corona of the pappus is pentaphyllous; and the calyx is imbricated with ſcales looſe at the top.

It is commonly called anemoſpermos, from the reſemblance of its ſeeds to thoſe of the anemone.

There are 11 ſpecies; all of which are natives of Ethiopia, and the Cape of Good Hope.

ARCTURUS, in aſtronomy, is a fixed ſtar, of the firſt magnitude, in the conſtellation of Arctophylax, or Bootes.

This ſtar was known to the ancients, as in the following verſe of Virgil:

> *Arcturum, pluviaſque Hyades, geminoſque Triones.*
>
> Vide Job ix. 9. xxxviii 32.

ARCUATION, in gardening, ſignifies a method of raiſing trees by layers, which is done in the following manner: viz.

Strong mother-plants muſt be planted in a clear border, in a ſtraight line, about ſix feet aſunder. When theſe have ſhot five or ſix main branches from the root, and as many collateral branches, the former muſt be bent to the ground, and there faſtened. The ſmall branches muſt be covered three inches deep upon the joints, and have a large baſon of earth made round them to hold the water.

About the middle of September they may be opened, and, if they have taken root, may be immediately removed into the nurſery; but if they have not ſufficiently extended their roots, they muſt be ſuffered to remain till the ſpring, and then tranſplanted.

ARCUCCIO, Arcutio, in mechanics, is a machine made of a board, covered with pieces of hoops, like the tilt of a waggon; uſed in Italy to prevent children from being overlaid and ſmothered by nurſes or others.

Every nurſe in Florence is obliged to lay her child in an arcutio, under pain of excommunication.

ARDASSES, in commerce, is the coarſeſt of all the ſilks of Perſia; and as it were the refuſe of each kind. In this ſenſe, they ſay, the *legis*, the *houſets*, the *choufs*, and the *payas ardaſſes*, to ſignify the worſt of thoſe four ſorts of Perſian ſilks.

ARDASSINES, in commerce, called in France *ablaques*: a very fine ſort of Perſian ſilks, little inferior in fineneſs to the fourbaſtis, or rather cherbaſſis, and yet it is little uſed in the ſilk manufactures of Lyons and Tours, becauſe that kind of ſilk will not bear hot water in the winding.

ARDEA, in ornithology, is a genus of the order of grallæ. The general characters of this order are theſe: The bill is ſtraight, ſharp, long, and ſomewhat compreſſed, with a furrow that runs from the noſtrils towards the point; the noſtrils are linear; and the feet have four toes.

Under this genus Linnæus comprehends the grus or crane, the ciconia or ſtork, and the ardea or heron.

There are 26 ſpecies, the principal of which are thoſe following, viz.

1. The pavonia, or crowned crane, which has an erect briſtly creſt, with the temples and two wattles naked. The head is black; the creſt yellowiſh, tipped with black at the top; the wings white; the feathers of the tail black, and of an equal length.

It is a native of Africa, particularly the coaſt of Guinea, as far as Cape Verd; at this laſt place they are ſaid to be exceedingly tame, and will often come into the court-yards to feed with the poultry. Theſe birds are often kept in our menageries, and, with ſhelter of nights, live a good while. Their chief food is ſuppoſed to be worms, and ſuch other things as the heron tribe uſually feed on; alſo vegetables of all kinds. It often ſleeps on one leg; runs very faſt; and not only flies well, but continues on the wing for a long time together. The fleſh is very tough.

2. The virgo has a ſtraight greeniſh bill and crimſon irides.

The crown of the head is aſh-colour; the upper part of the neck behind, and all the under parts, to the breaſt, black; the back, rump, and tail, and all the under part from the breaſt, are of a bluiſh aſh-colour: behind each eye ſprings a tuft of long white feathers, which decline downwards, and hang in an elegant manner: the quills and tail are black at the ends; the legs black.

This ſpecies is found in many parts of Africa and Aſia, where they frequent marſhes and rivers, their food is fiſh, like moſt of the heron genus. It is frequently kept in manageries, being endowed with great gentleneſs of manners, added to its being an elegant bird.

3. The leucogeranos of Pallas, or Siberian crane of Pennant, is four feet and an half when ſtanding erect. The bill is of a red colour; the irides are white: the plumage is white as ſnow, except the 10 firſt greater quills, with the coverts of them, which are black; the legs are long and red. This ſpecies inhabits the marſhes and lakes in Siberia. They are ſhy birds, and always upon their guard againſt an enemy; having a centinel to warn them of an approach: on the leaſt alarm they cry aloud, not unlike the ſwan, and fly off directly.

The ſportſman finds, in courſe, much difficulty in approaching them within gunſhot; for as they ſtand near five feet high from the ground, they are enabled to eſpy him at a greater diſtance. Sometimes the ſportſman approaches them under cover of a ſtalking horſe, or other object; at other times a ſmall dog will divert their attention, as they will without fear attack the dog, while his maſter gets within reach.

In breeding time, they are more bold, and will defend their young even againſt men, ſo that it is dangerous to come near their haunts. The male and female guard the neſt by turns.

4. The grus, or common crane, has a naked papillous crown; the prime feathers of the wings black; the body aſh-coloured; the prime feathers of the tail ragged.

This ſpecies is far ſpread, being met with in great flocks throughout northern Europe and Aſia; in Sweden, Ruſſia throughout, and Siberia as far as the river Anadyr, migrating even to the arctic circle. In Kamtſchatka they are only ſeen on the ſouthern promontory; are migratory, returning northward to breed in the ſpring, and generally chooſing the ſame places which had been occupied by them the ſeaſon before. In the winter they inhabit the warmer regions, ſuch as Egypt, Aleppo, India, and alſo the Cape of Good Hope, changing place with the ſeaſon.

In their migrations they frequently fly ſo high as not to be viſible; their paſſing only being known by the noiſe they make, which is louder than any other bird.

In France they are ſeen in ſpring and autumn; but are accounted mere paſſengers.

This ſpecies ſeems to have been formerly a native of Britain; as we find by Willoughby, (page 52,) that there was a penalty of twenty pence for deſtroying an egg of this bird; and Mr. Ray ſays, that in his time they were found during the winter in large flocks in Lincolnſhire and Cambridgeſhire: but at preſent the inhabitants of thoſe counties are ſcarcely acquainted with them; ſo that theſe birds ſeem now to have forſaken our iſland.

5. The Americana, or hooping crane, is a native of America: the crown of the head and temples are naked and papillous; the forehead, nape of the neck, and prime wing feathers, black; but the body is white: the under part of the head, as far as the lower chap, is red; the beak is yellowiſh, and jagged at the point; the feet red, and the prime tail-feathers white.

This ſpecies, frequent the mouths of the Savnana, Aratamaha, and other rivers near St. Auguſtine: in ſpring going to the north to breed, like the common crane, and returning, like that bird, to the ſouth in autumn.

In the ſummer they are found in Hudſon's Bay, at which place they arrive in May, and retire in September; and are chiefly met with in unfrequented places, in the neighbourhood of lakes, where they breed. The neſt is made on the ground, compoſed of graſs and feathers. They lay two white eggs, like thoſe of the ſwan, and ſit 20 days; the young are at firſt yellow, changing to white by degrees. Their food is chiefly worms and inſects, which it ſearches for at the bottom of ponds.

The natives of Hudſon's Bay call this ſpecies Wapawuchechauk.

6. The argil, or hurgil, is a very large ſpecies; from tip to tip of the wings meaſuring 14 feet 10 inches; and from the tip of the bill to the claws ſeven feet and a half: the bill is 16 inches round at the baſe, of different colours, and nearly of triangular ſhape; the feathers of the back and wings are very ſtrong, and of an iron colour; thoſe of the breaſt long: over the belly a great deal of down, of a dirty white: the legs and half the thighs are naked: the naked parts full three feet in length.

This monſter, as Ives terms it, inhabits Bengal, and is alſo found at Calcutta; at the laſt place, called Hurgill, or Argill. It majeſtically ſtalks along. The common opinion of the natives is, that the ſouls of the Bramins poſſeſs theſe birds. On opening one of theſe, a terapin, or land tortoiſe, 10 inches long, was found in its craw.

In Sumatra there is a great variety of the ſtork kind; ſome of a prodigious ſize, and otherwiſe curious; as the Boorong Cambing, and Booringoolar.

The ſame ſpecies ſeems to have been remarked by Mr. Smeathman in Africa, while reſident there; an adult of one of which will often meaſure ſeven feet when ſtanding erect. He deſcribes the plumage much the ſame as in Mr. Ives's bird; adding, that the gape is monſtrouſly wide; the head is covered with white down, thinly diſperſed, appearing not unlike a greyheaded man: on the middle of the neck before, a long, conic membrane, like a bladder, ſprinkled very thinly with ſhort down, riſing or falling as the animal moves the beak, and always appearing inflated. Theſe birds aſſemble in companies.

A young bird of this ſpecies was brought up tame, and preſented to the chief of the Bananas, where Mr. Smeathman lived; and being accuſtomed to be fed in the great hall, ſoon became familiar; duly attending that place at dinner-time, the ſervants were obliged to watch it narrowly, and to defend the proviſions with ſwitches in their hands; but, notwithſtanding this, it would frequently ſnatch off ſomething; it was once known to have purloined a whole boiled fowl, which it ſwallowed in an inſtant.

Its courage is not equal to its voracity; for a child of eight or ten years old would ſoon put it to flight with a ſwitch; though at firſt it ſeems to ſtand upon its defence, by threatening with its enormous bill widely extended, and crying out with a loud hoarſe voice, like a bear or a tiger.

It is an enemy to ſmall quadrupeds, as well as birds and reptiles; and deſtroys fowls and chickens, though it dare not attack a hen with her young openly: it preys alſo on rats, young kittens, and the like; and has been known to ſwallow a cat whole.

This bird uſed to fly about the iſland, and rooſt very high among the ſilk cotton trees; when it ſaw the dinner carrying acroſs the yard, it would dart from its ſtation, and enter promiſcuouſly with the women who carried in the diſhes.

7. The ciconia, or white ſtork, has naked eye-balls, and black prime wing-feathers. The ſkin below the feathers, as alſo the beak, feet, and claws, are of a blood colour. It is a native of Europe, Aſia, and Africa.

It feeds upon amphibious animals, and is ſuch an enemy to ſerpents, that it is reckoned almoſt a crime to kill a ſtork.

Storks are birds of paſſage; they ſpend the ſummer in Europe, and diſappear all at once; they go off to Egypt, Ethiopia, &c. before winter, and do not return till about the middle of March.

8. The major, or common heron, has a black creſt depending from the back part of the head, an aſh-coloured body, a black line and belt on the neck and breaſt. It is a native of Europe. It is remarkably light in proportion to its bulk, ſcarce weighing three pounds and an half: the length is three feet two inches. The body very ſmall, and always lean; the ſkin ſcarce thicker than gold-beater's ſkin.

It commits great devaſtation in our ponds; but being unprovided with webs to ſwim, nature has furniſhed it with very long legs to wade after its prey. It generally builds in trees, though ſometimes in high cliffs over the ſea, commonly in company with others, like rooks. It makes its neſt of ſticks, which it lines with wool, and lays five or ſix large eggs, of a pale green colour. During incubation, the male paſſes much of his time perched by the female. They deſert their neſts during the winter, excepting in February, when they reſort to repair them.

It was formerly a bird of game in England for heron-hawking, and was ſo favourite a diverſion of our anceſtors, that laws were enacted for the preſervation of the ſpecies; and the perſon who deſtroyed their eggs was liable to a penalty of twenty ſhillings for each offence.

Not to know the hawk from the heron-ſhaw was an old proverb, taken originally from this diverſion; but, in courſe of time, ſerved to expreſs great ignorance in any ſcience. In after times this proverb was abſurdly corrupted to, He does not know a *hawk* from a *hand-ſaw*.

This bird was formerly much eſteemed as food, and made a favourite diſh at the tables of the great, and is valued at the ſame rate as a pheaſant. It is ſaid to be very long-lived: by Mr. Keyſler's account it may exceed ſixty years; and, by a recent inſtance of one that was taken in Holland, by a hawk belonging to the Stadtholder, its longevity is again confirmed, the bird having a ſilver plate faſtened to one leg, with an inſcription, importing it had been before ſtruck by the elector of Cologne's hawks in 1735.

9. The garzetta, or egret, is creſted behind; the body is white, the beak black, and the feet greeniſh. It is an elegant bird, and weighs about one pound; the length twenty-four inches, and to the end of the legs thirty-two. It is a native of the Eaſt.

But formerly it was very frequent in Britain, as appears by ſome of the old bills of fare: in the famous feaſt of archbiſhop Neville, where we find no leſs than a hundred aſterides, egrets or egrittes, as it is differently ſpelt.

Perhaps the eſteem they were in as a delicacy during thoſe days, occaſioned their extirpation in our iſlands; abroad they are ſtill common, eſpecially in the ſouthern parts of Europe, where they appear in flocks.

The ſcapulars and the creſt were formerly much eſteemed as ornaments for caps and head-pieces; ſo that aigrette and egret came to ſignify any ornament to a cap, though originally the word was derived from *aigre, a cauſe de l'aigreur de ſa voix*.

10. The herodias, or criſtata maxima, is creſted behind, has a duſky-coloured back, reddiſh thighs, and the breaſt ſpeckled with oblong black ſpots. It is four feet and a half when erect; the beak is about eight inches from the angle of the mouth to the end of it; and the creſt is made up of long, narrow, brown feathers, the longeſt being five inches in length, which it can erect and let fall at pleaſure.

It is a native of Virginia, and feeds not only upon fiſh and frogs, but on lizards, efts, &c.

11. The ſtellaris, or bittern, has a ſmooth head; it is variegated through the whole body with dark-coloured ſpots of different figures and ſizes.

It is a native of Europe, and inhabits chiefly the fen-countries; where it is found ſkulking among reeds and ſedges: its uſual poſture is with the head and neck erect, and the beak pointed directly upwards.

It will ſuffer perſons to come very near it without riſing; and has been known to ſtrike at boys and ſportſmen, when wounded, and unable to make its eſcape.

It flies principally about the duſk of the evening, and then riſes in a very ſingular manner, by a ſpiral aſcent, till it is quite out of ſight. It makes a ſtrange noiſe when it is among the reeds, and a different, and a very ſingular one, as it riſes on the wing in the night.

It builds its neſt with the leaves of water-plants, on ſome dry clump among the reeds, and lays five or ſix eggs of a cinerous green colour.

The food of the bittern is chiefly frogs; not that it rejects fiſh, for ſmall trouts have been met with in their ſtomachs.

In the reign of Henry VIII. it was held in ſo much eſteem at table, that it was valued at one ſhilling. Its fleſh has much the flavour of a hare, and nothing of the fiſhineſs of that of the heron.

12. The violacea, or creſted bittern, has a white creſt; the body is variegated with black and white, and bluiſh below. Theſe birds are ſeen in Carolina in the rainy ſeaſons: but in the Bahama iſlands, they breed in buſhes growing among the rocks in prodigious numbers, and are of great uſe to the inhabitants there; who, while theſe birds are young and unable to fly, employ themſelves in taking them for the delicacy of their food. They are, in ſome of theſe rocky iſlands, ſo numerous, that in a few hours two men will load one of their calapatches, or little boats, taking them perching from off the rocks and buſhes, they making no attempt to eſcape, though almoſt full grown.

They are called by the Bahamians crab-catchers, crabs being what they moſtly ſubſiſt on; yet they are well taſted, and free from any rank or fiſhy favour.

ARDENT, in rhetoric, implies ſomething partaking of the ſame heat or favour as fire; and frequently uſed in figurative language, to ſignify an extraordinary zeal. Hence,

Ardent *Fever*, a ſynonyme of a burning fever.

Ardent *Spirits*, which imply thoſe diſtilled from fermented vegetables, and are ſo volatile as to catch fire eaſily, and to burn with great vehemence.

ARDENTES, in hiſtory, an appellation given to thoſe afflicted with the Ignis Sacer, or Eryſipelas. They were thus called, as ſeeming to be ſcorched or burnt with the diſeaſe. Hence the abbey of St. Genevieve in Paris is called *Domus Ardentium*, indicating that great numbers were cured of that diſtemper at the ſhrine of this ſaint, in the reign of Lewis VI.

ARDERS, in huſbandry, denotes the fallowings or plowings of land.

ARDUINA, in botany, is the boaſted lycium, of the pentandria claſs and monogynia order. The characters are few, viz. The corolla has but a ſingle petal; the ſtigma is bifid. The fruit is a double celled, being with a ſingle ſeed.

AREA, in general, denotes any plain ſurface on which we can walk, &c. The word is Latin, importing more properly a threſhing-floor; and his derived from *arere*, "to be dry."

Area, in geometry, denotes the ſuperficial content of any figure. Thus, if a figure, e. g. be in form of a ſquare, its ſide 40 feet, its area will be 1600 ſquare feet; or it contains 1600 little ſquares, each a foot every way.

AREB, is a kind of imaginary money uſed in the dominions of the great mogul. Four arebs are equal to one crou, or 100 lacs; one lac to 100,000 roupees.

ARECA, the Fauſel-Nut, in botany, is a genus of the order of palmæ pennatifoliæ.

The male has no calyx, but three petals, and nine ſtamina; the female has no calyx; the corolla has three petals, and the calyx is imbricated. There are two ſpecies, viz.

1. The cathecu, a native of India. This has no branches, but its leaves are very beautiful: they form a round tuft at the top of the trunk, which is as ſtraight as an arrow. It grows to the height of 25 or 35 feet, and is a great ornament in gardens.

The fruit which it bears is about the ſize of a walnut, and when ripe is aſtringent, but not unpalatable, and the ſhell is yellowiſh.

Of this fruit there is a prodigious conſumption in the Eaſt Indies, there being ſcarce any perſon, from the richeſt to the pooreſt, who does not uſe it; and the trade it produces is incredible.

The chief uſe that is made of areca is to chew it with the leaves of betel, mixing with it lime made of ſea-ſhells.

In order to chew it, they cut the areca into four quarters, and take one quarter of it, which they wrap up in a leaf of betel, over which they lay a little of the lime; afterwards they tie it, by twiſting it round.

This bit prepared for maſtication is called *pinang*; which is a Malayan word uſed all over the Eaſt Indies. The pinang provokes ſpitting very much, whether it be made with dried or freſh areca; the ſpittle is red, which colour the areca gives it. This maſtication cools the mouth, and faſtens the teeth and gums.

The Europeans who live at Batavia, or Malaca, and in the Sunda and Molucca iſlands, uſe pinang as much as the Indians do; and by waſhing their teeth they preſerve them white.

When eaten by itſelf, it impoveriſhes the blood, and cauſes the jaundice; but is not attended with theſe inconveniences when mixed in the uſual way with betel.

The beſt areca of the Indies comes from the iſland of Ceylon. The Dutch Eaſt-India company ſend great quantities of it in their ſhips to the kingdom of Bengal. The ſame company ſend ſome of it from time to time to Surat and Amadabat, for the uſe of the dyers in the dominions of the grand mogul.

2. The oleracea, or true cabbage-palm, is the moſt beautiful, and perhaps the talleſt, of all trees. The trunk is perfectly ſtraight, and marked with rings at the veſtigiæ of the footſtalks of the leaves. Near the ground it is about ſeven feet in circumference; but tapers as it aſcends, and attains the height of 170 or 200 feet. The bark is of an aſh colour till within 25 or 30 feet of the extremity of the tree; when it alters at once to a deep ſea-green, which continues to the top.

About five feet from the beginning of the green part upwards, the trunk is ſurrounded with its numerous branches in a circular manner; all the lowermoſt ſpreading horizontally with great regularity; and the extremities of many of the higher branches bend wavingly downwards, like ſo many plumes of feathers.

The branches are ſomewhat round underneath, and ſlightly grooved on the upper ſide; and are likewiſe decorated with a very great number of green pennated leaves: ſome of theſe are near three feet long, and an inch and an half broad, growing narrower towards their points, as well as gradually decreaſing in length towards the extremities of the branches.

As there are many thouſand leaves upon one tree; every branch bearing many ſcores upon it, and every leaf being ſet at a ſmall and equal diſtance from each other, the beauty of ſuch a regular lofty group of waving foliage, ſuſceptible of motion by the moſt gentle gale of wind, is not to be deſcribed.

The leaves produce from their texture a ſort of thread, which is uſed in making cordage of every kind, as well as fiſhing-nets, and is eſteemed ſtronger than thoſe uſually made from any other material.

Upon removing the large leaves, or branches, which ſurround the top of the trunk a little way above the beginning of the green bark, what is called the cabbage, is diſcovered lying in many thin, ſnow-white, brittle flakes, in taſte reſembling an almond, but ſweeter.

This ſubſtance, which cannot be procured without deſtroying the tree, is boiled, and eaten with mutton by the inhabitants of the Weſt Indies, after the ſame manner as turnips and cabbage are uſed with us; thongh it muſt appear the height of extravagant luxury, to fell ſo ſtately a tree, which would be an ornament to the moſt magnificent palace in Europe, to gratify the taſte of any epicure, eſpecially as there is but a very ſmall part of it eatable. That part called the cabbage-flower, grows from the part where the aſh-coloured trunk joins the green part already deſcribed.

Its firſt appearance is a green huſky ſpatha, growing to above 20 inches long, and about four broad; the inſide being full of ſmall white ſtringy filaments, full of alternate protuberant knobs, the ſmalleſt of theſe reſembling a fringe of coarſe white thread knatted: theſe are very numerous, and take their riſe from larger footſtalks; and thoſe footſtalks likewiſe are united to different parts of the large parent ſtalk of all.

As this huſky ſpatha is opened while thus young, the farinaceous yellow ſeed in embrio, reſembling fine ſaw-duſt, is very plentifully diſperſed among theſe ſtringy filaments, which anſwer the uſe of apices in other more regular flowers: theſe filaments being cleared of duſt, are pickled, and eſteemed the beſt pickles either in the Weſt Indies or in Europe.

But if the ſpatha is not cut down and opened whilſt young; when it grows ripe it will burſt; then the incloſed part, which whilſt young and tender is fit for pickling, will by that time have acquired an additional hardneſs, become ſoon after ligneous, grow buſhy, conſiſting of very many ſmall leaves, and in time produce a great number of ſmall oval thin-ſhelled nuts, about the bigneſs of unhuſked coffee-berries: theſe, being planted, produce young cabbage-trees.

The ſockets or grooves, formed by the broad part of the footſtalks of the branches, are uſed by the negroes as cradles for their children.

On the inner ſide of the very young footſtalks are tender pellicles, which when dried make writing paper.

The trunks ſerve as gutterings; the pith makes a ſort of ſago; and the nuts yield oil by decoction.

In the pith alſo, after the trees are felled, there breeds a kind of worms, or grubs, which are eaten and eſteemed a great delicacy by the French of Martinico, St. Domingo, and the adjacent iſlands.

Theſe worms, according to father Labat, are about two inches long, and of the thickneſs of one's finger; the head is black, and attached to the body without any diſtinction of neck. Their preparation for the table is as follows: they are ſtrung on wooden ſkewers before a fire; and as ſoon as heated, are rubbed over with raſpings of cruſt, ſalt, pepper, and nutmeg: this powder abſorbs all the fat, which during the cookery would otherwiſe eſcape; when properly roaſted, they are ſerved up with orange or citron ſauce.

Thoſe worms, when expoſed for ſome time to the ſun, yield an oil which is of great efficacy in the piles.

This oil ſhould never be heated before its application to the part affected; as repeated experiments have evinced that its ſpirit is totally diſſipated by the fire.

ARENA, in Roman antiquity, was a place where the gladiators fought; ſo called from its being always ſtrewed with ſand, to conceal from the view of the people the blood ſplit in the combat. Nero is ſaid to have ſtrewed the arena with gold duſt.

ARENARIA, or ſandwort, in botany, is a genus of the decandria trigynia claſs; and in the natural method ranking under the 22d order, caryophyllæ.

The calyx has five open leaves; the petals are five, and entire; the capſule is unilocular, and contains many ſeeds.

There are 17 ſpecies, and only ſeven of which are natives of Britain, viz.

The peploides, or ſea-ſandwort; the trinervis, or plantain-leaved ſandwort; the ſerpylli-folia, or leaſt ſandwort; the ſaxatilis, or mountain-ſandwort; the laricifolia, or larchleaved ſandwort; and the rubra, or purple-flowered ſandwort.

ARENARII, in antiquity, were gladiators who combated with beaſts in the arena, or amphitheatre. The arenarii were ſlaves of the loweſt rank; ſo that, though manumitted, they were not capable of being Roman citizens. They were the ſame with what were otherwiſe called beſtiarii.

ARENARIUM, in eccleſiaſtical hiſtory, denotes a cemetery or burying-ground. The arenaria were properly a kind of pits, or holes, under ground, in which the ancient Chriſtians not only buried their dead, but held their religious aſſemblies in times of perſecution.

ARENATION, in medical preſcription, implies the method of treating patients, by cauſing them to put their feet into warm ſand, as a dry bath, for the removal of obſtructions in the inteſtines and abdominal veſſels.

AREOLA, among anatomiſts, denotes the coloured circle ſurrounding the nipple of the breaſt.

AREOPAGUS, or rock of Mars, in hiſtory, implies a ſovereignty tribunal at Athens, famous for the juſtice and impartiality of its decrees, to which the gods themſelves are ſaid to have ſubmitted their differences.

Plutarch attributes the eſtabliſhment of the Areopagus to Solon. But authentic hiſtory records that it was originally inſtituted by Cecrops, in the year of the world 2553, the year in which Aaron died. But the beſt authorities allow, that it had been neglected, and attribute to him the honour of its reſtoration.

The city of Athens, before this famous court was eſtabliſhed, was governed by tribunals of a circumſcribed juriſdiction, which were multiplied by the moſt trifling accidents, which took no fixed political or civil form.

As each of thoſe tribunals could only act in proportion to the power delegated to it, it was impoſſible that ſo many different and unequal impreſſions ſhould give to the great machine of the ſtate, that uniform and regular movement which, by an impulſe always the ſame, would keep each part in the ſituation it ſhould maintain with relation to the whole.

To effect this univerſal and harmonious power, it was neceſſary to unite the different channels of public authority, which, by being too much diſtributed, loſt their force. This authority Solon collected, and placed it all in the court of Areopagus, which conſequently became the main ſpring of the government.

The judges of this court now took cognizance of crimes of every kind; and the ſame tribunal which inflicted capital puniſhment on murder, poiſoning, burning of houſes, theft, &c. ſtruck at the roots of thoſe crimes, by arraigning idleneſs, luxury, and debauchery.

Equally attentive to ſtimulate the indolence of the young, and the languor of the old, theſe ſage judges rouſed in the one laudable ambition to ſerve the ſtate, and reſtored to the others their former activity.

Satisfied that extremes produce the ſame effects, they thought the public had as much to fear from the exceſs of wealth as from the gripe of poverty.

Hence they exacted a minute account of the effects of every individual. And from this great ſeverity to idle citizens, who inſtead of being uſeful members in a ſtate, are its banes and its diſhonour, health was conſtantly retained in the legiſlature.

The ſtate was not ſatisfied with having eſtabliſhed good laws, but were extremely careful to ſee that they were obſerved. With this view, they had divided the city into quarters, and the country into cantons. Thus every thing paſſed under their eyes; nothing eſcaped them; they were acquainted with the private conduct of every citizen. Thoſe who had been guilty of any irregularity were cited before the magiſtrates, and were reprehended, or puniſhed in proportion to their miſdemeanour.

The Areopagites obliged the rich to relieve the poor. They repreſſed the intemperance of the youth by a ſevere diſcipline. Corruption in magiſtrates was ſuppreſſed by the puniſhments denounced againſt it; and the old men, at the ſight of the employments of the young, felt themſelves animated with a decree of juvenile vigour and activity.

The aſſiduous and painful exerciſe of their office made the Areopagites feel all the inconvenience of the ſituation of their tribunal, which was on the ſummit of a hill, and which was aſcended with difficulty; they therefore determined to remove it to a part of the city called the royal portico. It was a ſquare, expoſed to all the inclemencies of the weather.

When the judges, who aſſembled there in profound ſilence, had taken their places, they were incloſed by a thread, or cord, drawn around them.

They held their aſſemblies in the night, that their attention to public affairs might not be diverted by external objects; and, adds Lucian, that they might only be influenced by the arguments, and not by the preſence and action of the ſpeakers. This circumſtance explains a paſſage in Athenææs, who tells us, that none knew the numbers or faces of the Areopagites.

The cuſtom of adminiſtring juſtice in the open air was not peculiar to them. It was followed by all the other tribunals when they tried for murder; for two reaſons: 1ſt, That the judges, the ſworn protectors of innocence, might not be hurt by being under cover with criminals, whoſe hands were polluted with blood. 2dly, That the accuſer and the accuſed might not be under the ſame roof.

When all the members of the ſenate were convened, a herald enjoined ſilence, and ordered the people to retire. As ſoon as they had departed, the aſſembly proceeded to buſineſs; and as they deemed the leaſt preference a flagrant injuſtice, the cauſes which they were to determine were drawn by a kind of lottery; and the ſame chance which brought them up, diſtributed them to different numbers of judges, ſmall or great, according to the importance of the ſeveral cauſes.

In early times, the parties themſelves ſtated their cauſe in a ſimple manner. The eloquence of advocates was thought a dangerous talent, fit only to varniſh crimes. But afterwards the Areopagus, on this point, relaxed from their ſeverity: at firſt the accuſed, and ſoon after the accuſers, were permitted to engage thoſe to make the attack and the defence, whoſe profeſſion it was to exert the art of ſpeaking, for others, with accuracy and elegance.

Sextus Empiricus ſeems not to have ſufficiently diſtinguiſhed times, where he ſays, that the court of Areopagus did not ſuffer thoſe who are to be tried at their bar to avail themſelves of the abilities of others. What undoubtedly led him into that miſtake, was an inviolable cuſtom of that tribunal, which prohibited, in pleadings, all that warm and pictureſque oratory which ſeduces the judgment and inflames the paſſions. When the ſuffrages were collected, each perſon gave his in ſilence. They voted with a ſmall flint, which they held betwixt the thumb and the two next fingers, and which they put into one of the two urns that ſtood in a corner of the hall. One ſtood before the other. The firſt was called the *urn of death*; the ſecond, the *urn of compaſſion*. That of death was of braſs, and was termed *proper*; that of compaſſion was of wood, and was termed *improper*. The judges commonly brought their flint to the aſſembly, and put it into the urn; but that all the ſuffrages might be collected, the herald took the two urns, and preſented them, one after another, to every ſenator, commanding him, in the name of the republic, no longer to defer his acquittal or condemnation.

After the ſuffrages were collected, they were taken out of the two urns, and put into a third vaſe of braſs. They were then counted; and as the number of white or of black flints was higher or inferior, one of the judges drew with his nail a ſhorter or a longer line on a tablet with a waxen ſurface, on which the reſult of each cauſe was marked. The ſhort line expreſſed *acquittal*; the long, *condemnation*.

With regard to the emoluments of the judges, they were as moderate as thoſe of the advocates. The length of the proceſs did not enhance its expence; and when the deciſion of a cauſe was poſtponed till the next day, the committee were only paid an obolus on that day. Hence Mercury, in Lucian, is ſurpriſed that ſuch ſenſible old men as the ſenators of Areopagus were, ſhould ſell at ſo low a price the trouble of aſcending ſo high.

As to the number of the judges which compoſed the Areopagus, ſome authors, attentive only to a part of Solon's regulations, by which he enacted, that for the future, none but the nine archons ſhould be admitted members of the Areopagus, have imagined, that this tribunal was filled anew every year, and that it never conſiſted of more than nine magiſtrates. This opinion, and ſome others, are refuted by the circumſtantial account which Diogenes Laertius gives us of the condemnation of Socrates. This great man had wiſhed to ſubſtitute a rational hypotheſis for the fabulous and extravagant ſyſtem of religion, which prevailed in his time. His project, however laudable, appeared impious in the eye of ſuperſtition. Information was laid againſt him before the Areopagus, and he had as many accuſers as fellow-citizens. After the charges and the anſwers were heard, they proceeded to ſuffrages. The opinions were divided, but not equally, for the number of thoſe who condemned him exceeded by 281 the number of thoſe who declared him innocent. He made an ironical reply to this iniquitous ſentence, by telling his judges, that he took it for granted, they would admit him to a maintenance in the Prytanæum. On this ſarſcaſm, 80 of thoſe who had voted in his favour forſook him, went over to the oppoſite party, and condemned him to die. Here then we have 361 judges who condemn; to whom if we add thoſe who perſiſt in acquitting him, the number muſt be conſiderable.

Before this tribunal St. Paul was called to give an account of his doctrine, and converted Dionyſius one of their number.

The end of this court of judicature is as obſcure as its origin, which was derived from very remote antiquity. It exiſted, with the other magiſtracies, in the time of Pauſanias, i. e. in the 2d century. The term of its ſubſequent duration is not aſcertained; but a writer, who lived under the emperors Theodoſius the Elder and Younger, in the 5th century, mentions it as being then extinct.

ARETHUSA, in mythology, the daughter of Nereus and Coris, and the companion of Diana, who changed her into a fountain to deliver her from the purſuit of her lover Alpheus.

Arethusa, in botany, is a genus of the gynandria diandria claſs; and in the natural method ranking under the 7th order, Orchideæ.

The generic character is taken from the nectarium, which is tubular, ſituated at the bottom of the corolla, and the inferior labium fixed to the ſtylus. There are four ſpecies; all natives of America, except the capenſis, which is only found at the Cape of Good Hope.

ARETIA, in botany, is a genus of the pentandria monogynia claſs; and in the natural method ranking under the 21ſt order, Pretiæ. The corolla is divided into five parts; the tube of the corolla ovated; and the capſule globular, and conſiſts of but one cell. There is but one ſpecies, viz. the alpina.

ARETOLOGI, or Aretalogi, in antiquity, were a ſort of philoſophical jeſters, chiefly of the Cynic or Stoic tribe, who, having no ſchool or diſciples of their own, attended the tables of great men, and entertained them in their banquets with diſputations on virtue, vice, and other popular topics.

ARETOLOGY, in philoſophy, implies the whole doctrine of morality, which defines virtue and the mode of acquiring it.

ARGAL, the ſame as tartar.

ARGEA, or Argei, in Roman antiquity, were thirty human figures, made of ruſhes, thrown annually by the prieſts, or veſtals into the Tiber, on the day of the ides of May. The original inſtitution of this cuſtom was, that the barbarous nation who firſt inhabited theſe parts caſt all the Greeks they could meet with into the Tiber: for Argians was a common name for all Grecians: but Hercules perſuaded them to quit ſo inhuman a practice, and to purge themſelves of the crime by commemorating this ſolemnity.

ARGEMONE, or Prickly Poppy, in botany, is a genus of the monogynia order, belonging to the polyandria claſs; in the natural method the 27th order, Rhæadeæ.

The corolla conſiſts of ſix petals; the calyx triphyllous; and the capſule ſemivalved.

There are three ſpecies, all natives of the Weſt Indies.

ARGENT, is the common French heraldic word for ſilver, of which metal all white fields or charges are ſuppoſed to conſiſt.

Argent of itſelf is uſed in heraldry to ſignify purity, innocence, beauty, and gentleneſs; and, according to G. Leigh, if it is compounded with

Gul.	it ſignifies	boldneſs;
Azu.		courteſy;
Ver.		virtue;
Pur.		favour;
Sab.		religion.

ARGENTARIA *Creta*, or ſilver chalk, in natural hiſtory, is a pure white earth, found in Pruſſia, much eſteemed for cleaning plate.

ARGENTARIUS, in Roman antiquity, was a ſynonymous term for a money changer or banker. The argentarii were monied people, who made a profit either by the changing, or lending of money at intereſt. Theſe had their *tabernæ*, or offices, in the *forum Romanum*, built there as early as the reign of L. Tarquinius Priſcus.

The argentarii and fœneratores were much hated on account of their covetouſneſs and extortion.

ARGENTATI Milites, in antiquity. Livy, lib. vi. ſpeaks of *argentati milites*, as diſtinguiſhed from *aurati*. Aquinas ſuppoſes theſe to have been ſimilar to the argyraſpides and chryſaſpides; but the deſcriptions do not quadrate. Livy only repreſents the argentati as cloathed in white linen coats.

ARGENTIL, in botany, is a ſynonyme of the aphanes, parſley piert, or parſley breakſtone.

ARGENTINA, in ichthyology, is a genus of fiſhes belonging to the order of abdominales. The generic characters of which are, the teeth are in the tongue as well as the jaws; the branchioſtege membrane has eight radii or rays; the anus is near the tail; and the belly-fins conſiſt of many rays.

There are two ſpecies, viz.

1. The ſphyræan has 15 rays in the fin at the anus; the air-bladder of this ſpecies is conical on both ſides, and ſhines like ſilver.

2. The carolina has likewiſe 15 rays in the fin near the anus; the tail is forked, and the lateral lines are ſtraight. It inhabits the freſh waters of Carolina.

ARGENTINUS, in mythology, was a deity worſhipped by the ancients, as the god of ſilver coin; as Æſculanus, whom they made his father, was the god of braſs money, which was in uſe before ſilver.

ARGENTUM, in natural hiſtory, is ſynonymous with Silver.

Argentum *Album*, in old records, imply ſilver coin or pieces of bullion that anciently paſſed for money. By Doomſday tenure, ſome rents to the king were paid in *argento albo*, common ſilver pieces of money: other rents in *libris urſis et penſatis*, in metal of full weight and purity: in the next age, that rent which was paid in money, was called *blanch fearm*, and afterwards *white rent*; and what was paid in proviſions, was termed *black mail*.

Argentum *Dei*, God's penny, in Law anciently ſignified earneſt-money, or money given to bind a bargain; in ſome places called *erles*, or *arles*, and by the civilians and canoniſts, *arrhæ*.

Argnetum *Muſivum*, in the fine arts, is a maſs conſiſting of ſilver-like flakes, uſed for the colouring of plaſter-figures, and for other purpoſes, as pigment.

It conſiſts of an amalgam of equal parts of tin, biſmuth, and mercury. It is to be mixed with white of eggs, or ſpirit varniſh, and then applied to the intended work, which is afterwards to be burniſhed.

Argentum *Vivum*, mercury or quickſilver, is the ſame as Mercury.

ARGIL, in ornithology, denotes a ſpecies of ardea, or heron.

ARGILLA, clay, in natural hiſtory, is ſynonymous with Clay.

ARGIVI, or Argeii, in geography, denotes the people of Argeia or Argolis.

ARGO, in mythology, was a ſhip celebrated by the poets: being that in which the Argonauts, of whom Jaſon was the chief, made their expedition in queſt of the golden fleece.

Jaſon having happily accompliſhed his enterpriſe, conſecrated the ſhip to Neptune, in the Iſthmus of Corinth; from whence it was tranſlated into heaven, and made a conſtellation.

Argo *Navis, the Ship Argo*, in aſtronomy, denotes a conſtellation in the ſouthern hemiſphere, whoſe ſtars, in Ptolemy's catalogue, are 45; in Tycho's, 11; in the Britannic catalogue, 64.

ARGONAUTA, in entomology, is the name of a genus of ſhell-fiſh belonging to the order of vermes teſtacea. The ſhell conſiſts of one ſpiral involuted valve.

There are two ſpecies, viz.

1. The argo, with a ſubdented carina, which is found in the Mediterranean Sea and Indian ocean.

The ſhell ſeems no thicker than a piece of paper; and the fiſh that inhabits it is a ſepia.

It has been imagined that men firſt learned the method of ſailing in veſſels from what they ſaw practiſed by this creature.

When it is to ſail, it extends two of its arms on high; and between theſe ſupports a membrane, which it throws out on this occaſion: this ſerves for its ſail; and the two other arms it hangs out of the ſhell, to ſerve occaſionally either as oars or as a ſteerage; but this laſt office is generally ſerved by the tail. When the ſea is calm, it is common to ſee numbers of theſe creatures diverting themſelves with ſailing about in this manner; but as ſoon as a ſtorm riſes, or any thing gives them diſturbance, they draw in their legs, and take in as much water as makes them ſomewhat heavier than the ſea-water in which they ſwim, and then they they ſink to the bottom.

The manner of their voiding this abundant water, when they would riſe again, is by a number of holes, of which their legs are full.

2. The cymbium, with a blunt plaited carina. This ſpecies is very ſmall, and is found in the Mediterranean Sea, and the Bay of Biſcay.

ARGONAUTIC, implies ſomething belonging to the Argonauts.

The argonautic expedition is one of the greateſt epochas or periods of hiſtory which Sir Iſaac Newton endeavours to ſettle, and from thence to rectify the ancient chronology. This he ſhows to have been about thirty years earlier than the taking of Troy, and 43 years later than the death of Solomon.

ARGONAUTICA, in literary hiſtory, denotes poems on the ſubject and expeditions of the argonauts.

We have the *Argonautics* of Orpheus in epic verſe, publiſhed by H. Stephens; the *Argonauticon* of Valerius Flaccus, in eight books of Latin heroics, in imitation of Apollonius, with reſpect to which Burman obſerves that the imitator has often ſurpaſſed the original; the *Argonautics* of Apollonius Rhodius, an heroic poem, conſiſting of four books, *opus*, as Quintilian calls it, *non contemnendum*.

ARGONAUTS, in antiquity, a company of illuſtrious Greeks, 51 in number who embarked along with Jaſon, in the ſhip Argo, from Colchis, with a deſign to obtain the golden fleece.

Argonauts *of St Nicholas*, was a military order inſtituted by Charles III. king of Naples, in the year 1382, for the advancement of navigation.

They wore a collar of ſhells, incloſed in a ſilver creſcent, whence hung a ſhip with this device, *Non credo tempori*, "I do not truſt time."

Hence theſe Argonaut knights came to be called *knights of the ſhell.* They received the order of St. Baſil, archbiſhop of Naples; and held their aſſemblies in the church of St. Nicholas, their patron.

ARGOPHYLLUM, White-leaf, in botany, a genus of the monogynia order, belonging to the pentandria claſs of plants. The capſule is trilocular; the nectarium is pyramidal, pentagonous, and the length of the corolla.

There is but one ſpecies, the netidum or gloſſy, a native of New Caledonia.

ARGUMENT, in rhetoric and logic, denotes an inference drawn from the premiſes; the truth of which is held indiſputable, or at leaſt highly probable.

Argument, in matters of literature, denotes the abridgment or heads of a book, hiſtory, comedy, chapter, &c.

ARGUMENTATION, is the act of inventing or framing arguments, of making inductions, and drawing concluſions.

Argumentation, according to Cicero, is the delivering or unfolding of an argument.

The matter of argumentation, is propoſitions; the form, their due diſpoſition, with regard to one another, ſo as a concluſion may be drawn from them.

Argus *Shell*, is a ſpecies of porcelain-ſhell, beautifully variegated with ſpots, reſembling in ſome meaſure thoſe in a peacock's tail.

ARGUTIÆ, in rhetoric, are witty and acute ſayings, which commonly ſignify ſomething further than what at firſt ſight they ſeem to import.

Argutiæ *ab Alluſione*, are thoſe in which alluſion is made to ſome hiſtory, fable, ſentence, proverb, or the like.

Argutiæ *a Comparatis*, when two things are compared together, which yet at firſt ſight appear very different from each other, but ſo as to make a kind of ſimile or diſſimile.

Argutiæ *a Repugnantibus*, is when two things meet in a ſubject, which yet regularly cannot be therein; or when two things are oppoſed to each other, yet the epithet of the one is attributed to the other.

ARGYRASPIDES, or Argyroaspides, in antiquity, were perſons armed with ſilver bucklers, or bucklers ſilvered.

Theſe, according to Quintus Curtius, made the ſecond corps of Alexander's army; the firſt was the phalanx.

According to Juſtin's account, lib. xii. cap. 7. Alexander having penetrated into India, and extended his empire as far as the ocean; for a monument of his glory, ordered the armour of his ſoldiers, and the houſings of his horſes, to be adorned with ſilver.

And hence commanded them to be called *argyraſpides,* from the Greek *αργυρος*, *ſilver*, and *ασπις*, *buckler*.

ARGYRIPÆ, is the ſame as argos hippium.

ARIADNÆA, in Grecian antiquity, were two feſtivals at Naxos, in honour of two women named Ariadne. One of them was the daughter of king Minos, they had, in the ſolemnity, dedicated to her, a ſhew of ſorrow and mourning; and, in memory of her being left by Theſeus near the time of child-birth, it was uſual for a young man to lie down and counterfeit all the agonies of a woman in labour.

This feſtival is ſaid to be firſt inſtituted by Theſeus, to atone for his ingratitude to that princeſs.

The other Ariadne was thought to be of a gay and ſprightly temper; and therefore her feſtival was obſerved with muſic and other expreſſions of mirth and joy.

ARIANS, in church hiſtory, denote the followers of Arius, a preſbyter of the church of Alexandria, about the year 315; who maintained, that the Son of God was totally and eſſentially diſtinct from the Father; and that he was the firſt and nobleſt of thoſe beings whom God had created; and was the inſtrument by whoſe ſubordinate operation he formed the univerſe; therefore inferior to the Father both in nature and dignity; and that the Holy Ghoſt was not God, but created by the power of the Son.

ARICINA, in mythology, was a ſurname of Diana; under which appellation ſhe was honoured in the foreſt Aricine, ſo called from Aricia a princeſs of the blood-royal of Athens.

Hippolytus, to whom this princeſs was married, is ſaid to have erected a temple to Diana in this foreſt.

ARIDAS, a kind of taffety, manufactured in the Eaſt Indies from a ſhining thread which is produced from certain herbs, whence they are ſtyled *aridas of herbs.*

ARIDED, in aſtronomy, is a fixed ſtar of the ſecond magnitude in the ſwan's tail.

ARIDULLAM, in natural hiſtory, is a kind of zarnich found in the Eaſt Indies.

ARIDURA, in the materia medica, implies a declenſion in the animal functions; hence all conſumptive, hectic or decaying of the corporeal ſyſtem are defined as Aridmaical complaints.

ARIES, in zoology, is ſynonymous with Ovis.

Aries, the battering ram, the ſame as the Battering *Ram.*

Aries, in aſtronomy, is a conſtellation of fixed ſtars, drawn on the globe, in the figure of a ram. It is the firſt of the twelve ſigns of the zodiac, from which a twelfth part of the ecliptic takes its denomination.

ARIETATION, in natural hiſtory, is a ſynonymous term with Earthquake.

ARILLUS, is a technical term, invented by Linnæus, and defined to be the proper exterior coat or covering of the ſeed, which falls off ſpontaneouſly.

All ſeeds are furniſhed with an arillus; for in many, a dry covering, or ſcarf-ſkin, ſupplies its place. In Jeſſamy; hound's tongue, *cynogloſſum*; cucumber; fraxinella, *dictamnus*; ſtaff-tree, *celaſtrus*; ſpindle-tree, *euonymus*; African ſpiræa, *dioſma*; and the coffee-tree, *coffea*; it is very conſpicuous.

The different ſkins or coverings of the ſeeds of plants are adapted for receiving the nutritive juices, and tranſmitting them within.

ARIMANIUS, in mythology, was the evil good of the ancient Perſians.

The Perſian Magi held two principles: a good dæmon, or god, and an evil one: the firſt was deemed the author of all good, and the other of all evil: the former they ſuppoſed to be repreſented by light, and the latter by darkneſs, as their trueſt ſymbols.

ARISI, a ſynonymous term for the rice of India.

ARISTA, in botanical language, implies the long needle like beard, generally called the awn of grain: barley and bire have very long and conſpicuous characters of this deſcription.

ARISTÆUS, in mythology, is ſynonymous with Equirinus, or Aquarius.

ARISTIDA, in botany, is a genus of the triandria dygnia claſs, or 4th natural order, gramina. The generic characters of which are; the calyx has a double valve, the corolla one valve, and ariſted with 3 awns at the point.

There are three ſpecies, viz. 1. The Aſcenſionis, a native of Aſcenſion Iſland. 2. The Americana, a native of Jamaica; and 3. The Plumoſa, a native of South America.

ARISTOCRACY, in national polity, implies a form of government, where the ſupreme authority is lodged in the nobility. This of all forms is the moſt liable to error, as faction and undue influence frequently overturn the juſt rights of juriſprudence. The republic of Venice is in many reſpects a form of government under this deſcription, but in others partakes of oligarchy. The beſt government in the power of human wiſdom to form, is that of two or three eſtates in the repreſentation of the people, headed by a limitted monarchy; where emulation ſeldom fails to reward thoſe whoſe deſerts merit the attention of the king and country they ſerve.

ARISTOTELIA, in antiquity, denote annual feaſts celebrated in honour of Ariſtotle, by the citizens of Stagira, out of gratitude for his having obtained a charter to rebuild their city from Alexander; which had been deſtroyed by Philip his father.

ARISTOTLEAN, or Aristotelian, implies ſomething that relates to Ariſtotle's philoſophy.

ARISTOTUS, in ichthyology, is a ſynonymous term for the ſhad.

Arithmetic is juſtly ſtiled the baſis of Mathematical Learning; for all the other branches are in ſome meaſure beholden to it, although it ſtands ſolely independent, and fixed upon its own principles.

It is therefore eſſentially neceſſary for every perſon, who deſires to attain a competent knowledge of the mathematics, to go regularly through the ſeveral rules of arithmetic, and to make himſelf fully acquainted with the properties of numbers.

In this Syſtem, I have arranged the ſeveral parts in the moſt natural order; having gone through Addition, Subtraction, Multiplication, and Diviſion of whole numbers, *and Reduction alſo, before I have entered upon Addition, Subtraction, &c. of* broken numbers, *or thoſe of different denominations; as it would be abſurd to expect any one to add up numbers, conſiſting of various denominations, (eſpecially where the ſums are large) without a previous knowledge how to reduce a Number of one denomination to that of another.*

I have alſo introduced Fractions and Decimals before the Rule of Three and other parts of Arithmetic, by which means the ſtudent is enabled to purſue the quickeſt and beſt methods of computation; and thereby much time is ſaved, which otherwiſe would be employed in purſuing ſuch inelegant and tedious forms of operation, as are in no caſe accommodated to the diſpatch of buſineſs.

In the Rule of Three I have given a better method of ſtating and judging of the nature of the queſtions, than has been hitherto in uſe.

I have likewiſe introduced ſeveral new methods of contracting Arithmetical Operations, and have advanced additional Caſes in ſome Rules, which I believe have never before appeared. Such are to be found under the Articles Multiplication, Rule of Three, Fellowship, Interest, Alligation, &c. *and in particular I have given the inveſtigation of a* GENERAL METHOD OF EXTRACTING THE ROOTS OF ALL POWERS BY PROPORTION, *together with another new and expeditious way of* extracting the Cube Root.

I have every where, either introduced more expeditious methods of operation, than have hitherto been given, or followed the beſt improvements of the moſt valuable authors, namely, Mr. Malcolm, Dr. Hutton, Mr. Emmerſon, Mr. Bonnycaſtle, &c.

Nothing in this Syſtem is inſerted upon the bare credit of others, having carefully gone through every computation; I have alſo extended the ſubject to its utmoſt limits, ſo that there is nothing belonging to it, but what is here amply treated of.

Excise Office, Broad Street. *R. MOODY.*

A NEW SYSTEM OF ARITHMETIC.

ARITHMETIC, from the Greek Αριθμετικὴ, is the art of numbering, or the art of computing by numbers.

When a number is made up, or compoſed of intire units, or individuals, it is called a *whole* number. That which is not ſo compoſed, but contains part of an unit, is named a *fractional* number. When an unit contains ten, an hundred, a thouſand, ten thouſand, &c. of ſuch parts, they are termed *decimal* parts, and the Arithmetic of Numbers in which they occur, is called *decimal Arithmetic*. When twelve of the parts make an unit, they are ſtiled *duodecimal* parts; and the Arithmetic thereof is named *duodecimal Arithmetic*.

If ſixty of the parts go to an unit, they are called *ſexageſimal* parts, and the proper management thereof in computations is termed *ſexageſimal Arithmetic*.

In general, every other kind of Arithmetic is named *common* or *vulgar Arithmetic*, except ſpecious or univerſal Arithmetic, for which ſee ALGEBRA.

That Arithmetic was practiſed very early in the world is beyond doubt, for the idea of number is conveyed from every thing about us; but when, where, or by whom it was firſt taught, there are no certain records. The Moſaic account of the Antedeluvian world affords a ſtrong preſumption, that the art of numbering had arrived to a tolerable degree of perfection before the flood. For their dividing the year into months and days, ſo little differing from the preſent diviſion of time, together with their ſtrict chronology of events, ſuch as the beginning, progreſs, and end of the Flood. The births, and ages of the patriarchs, &c. all argue their knowledge of numbers.

Wherefore, I cannot ſubſcribe with thoſe who think the art had its riſe among the Phœnicians, who are reputed to have been the firſt merchants after the Flood; though I doubt not but they cultivated and improved it; and it is probable, that by them it was carried into Egypt, and that it paſſed from thence into Greece.

In order to render Arithmetical computations uſeful to ſociety, the firſt thing would be to eſtabliſh ſome common method of notation, on which computations might be founded. It would then be natural to enquire into the relations and properties of numbers, and to invent methods of operation.

The Greeks, Hebrews, and other Eaſtern nations in their notation, uſed the letters of the alphabet; but their methods were confined and very incommodious, which rendered their computations exceeding difficult and laborious, as is obſervable from the ſpecimens in ſome of the fragments of Pappus, and the Commentaries of Utocius on Archimedes Treatiſe of the Circle.

The method of notation now in uſe with us, is ſaid to have been received from the Arabians, who learnt it of the Indians. The time of its invention is unknown; but that neither the ancient Greeks nor Romans were acquainted with it, is almoſt certain. For Maximus Planudes, who wrote about the beginning of the 14th century, is the firſt Greek writer who has treated of Arithmetic according to the preſent mode of numbering, which was at leaſt three hundred years after it was known in Europe. For Doctor Wallis has clearly evinced that a monk, named Gerbertus, (afterwards Pope Sylveſter II.) who did not die till A. D. 1003, was well acquainted with our notation, having learned it in Spain, from whence he carried it into France many years before his death.

It is reported that it came into Spain by means of the Moors; and it is almoſt certain, that it was in uſe in England as early as the middle of the 12th century. There is a book extant of Joannes de Sacra Boſco, which was written in England about the middle of the 13th century, according to the preſent notation; and conſiderable improvements had been here made in this kind of computations before then.

The oldeſt treatiſe on the theory of Arithmetic is comprized in the 7th, 8th, and 9th books of Euclid's Elements. It relates chiefly to the doctrine of Proportion, and Prime, and Compoſite Numbers. The next is that of Nichomacus, the Pythagorean; his treatiſe conſiſts chiefly of the diviſion of numbers into certain kinds and claſſes, as Plain, Solid, Triangular, Quadrangular, and other ſpecies of figurate numbers: alſo numbers odd and even, &c. Some are of opinion that Nichomacus lived before Euclid.

Boethus, who wrote a Latin Treatiſe of Arithmetic in the time of Theodorick, the Goth, is the next remarkable author on this ſubject; he, however, it is ſuppoſed took moſt of his works from Nichomacus. Afterwards Pſellus, and Jodochus Willichius, wrote in Greek, but none of theſe were acquainted with the Arabian notation. The firſt author of any conſequence who uſed the modern way of computing, was Jordanus of Namur. He flouriſhed about A. D. 1200: and his Arithmetic was afterwards publiſhed and demonſtrated by Joannes Faber Stapulenſis in the 15th century; who alſo himſelf publiſhed a treatiſe containing moſt of the propoſitions of Euclid and Boethus, with many other curious and uſeful theorems. The ſame author alſo wrote a book under the title of Algoriſmus Demonſtratus, illuſtrating the new art of computation by Arabic Figures, the manuſcript of which, as Doctor Wallis informs us, is in the Savillian Library at Oxford.

In A. D. 1499, an Italian, named Lucas de Burgo, publiſhed a valuable Treatiſe of Arithmetic, both as to Theory and Practice. Alſo in the courſe of the following century, Nicholas Tartaglia, an Italian; Clavius and Ramus, both Frenchmen; Stifelius and Heniſchius, Germans; Buckley, Diggs, and Record, &c. Engliſhmen; employed themſelves in improving the art.

Theſe have been followed by Wingate, Tacquet, Moor, Parſon, Baker, Kerſey, Wells, Kocker, Fiſher, and a variety of other authors too tedious to mention; indeed, authors on this ſubject are become almoſt innumerable.

Having given a ſhort hiſtorical account of Arithmetic, I ſhall proceed to ſhew its operations.

ARTICLE I.

NOTATION.

DEFINITION.

I. Notation is the art of expreſſing properly and methodically any propoſed number in figures or characters.

II. Number is the name of that idea or notion, under which, things, being conſidered, are ſaid to be *one* or *many*.

III. Every number is expreſſible by the due ordering of the following figures; viz. 1, which, of itſelf, ſignifies One, or an Unit; 2, which denotes two; 3, three; 4, four; 5, five; 6, ſix; 7, ſeven; 8, eight; 9, nine; 0, nothing.

IV. A whole number is compoſed of entire units.

V. A fractional number is either only ſome part or parts of an unit, or is compoſed both of entire units, and of ſome part or parts of an unit. In the former caſe, it is named a proper fraction; in the latter, it is called a mixed number.

VI. A whole number is alſo of two ſorts, ſimple and compound.

A ſimple whole number conſiſts either of entire units, tens, hundreds, thouſands, &c. not exceeding nine.

A compound whole number conſiſts not of either units, tens, hundreds, thouſands, &c. alone, but of ſome two or more of theſe combined.

For inſtance, ten, twenty, (or two tens) fifty, (or five tens) one hundred, three hundred, five thouſand, &c. are ſimple whole numbers. And twelve, (or ten and two) twenty-four, (or twenty and four) an hundred and forty-five, three thouſand two hundred and ſixty, &c. are compound whole numbers.

VII. As all units (under ten) are expreſſed by the nine digits, 1, 2, 3, 4, 5, 6, 7, 8, 9, ſo all ſimple whole numbers of tens, hundreds, thouſands, &c. are expreſſed by the ſame figures with cyphers annexed; tens having one cypher annexed; hundreds, two; thouſands, three, &c.

Thus 10, ſignifies ten; 20, twenty; 30, thirty; 40, forty; 300, three hundred; 5000, five thouſand, &c.

COR. Hence, a cypher, though of itſelf, or when alone, ſignifies nothing, yet, when placed to the right of any figure, it increaſes its value tenfold.

VIII. As compound whole numbers conſiſt of different ſimple whole numbers combined together, ſo ſuch numbers are expreſſed by the combining or joining together the ſeveral figures denoting them. Thus twenty-five conſiſts of 20 and 5; the cypher in the former denoting that there are no units, and ſignifies 20 without any addition; but, putting the five in the cypher's place, we have 25, which is the true expreſſion for twenty-five.

Again: three hundred and ſixty-four, conſiſts of 300, 60, and 4; but joining theſe together, 60 and 4 make 64, and joining this to 300, the whole is 364.

Furthermore, eight thouſand, four hundred and ſeventy-five, conſiſts of 8000; 400, 70, and 5; and 70 and 5 make 75; alſo 75 and 400, make 475; and 475 and 8000, make 8475, the propoſed number; and ſo for others.

COR. I. Hence the firſt place towards the right hand of any whole number, conſiſts of units; the ſecond, of tens; the third, of hundreds; the fourth, of thouſands; &c. the value of any figure being increaſed or decreaſed in value, according as its ſtation is removed one place more to the left or right hand.

COR. II. Hence, by this management, any number, however great, is eaſily and readily expreſſed.

Here follows a table, denoting the values of any number, to the hundred thouſand of millions.

Hundreds of Thouſands of Millions.	Tens of Thouſands of Millions.	Thouſands of Millions.	Hundreds of Millions.	Tens of Millions.	Millions.	Hundreds of Thouſands.	Tens of Thouſands.	Thouſands.	Hundreds.	Tens.	Units.
4	5	6,	9	8	7,	5	6	2,	3	4	1

In this table, the firſt figure to the right, taken ſingly, denotes 1; if two are taken, they make 41; three, make three hundred and forty-one; four, two thouſand, three hundred and forty-one; five, ſixty-two thouſand, three hundred and forty-one; ſix, five hundred and ſixty-two thouſand, three hundred and forty-one; ſeven, ſeven millions, five hundred and ſixty-two thouſand, three hundred and forty-one; eight, eighty-ſeven millions, five hundred, &c. &c. as before; nine, nine hundred and eighty-ſeven millions, five hundred, &c. &c. ten, ſix thouſand, nine hundred and eighty-ſeven millions, &c. &c. eleven, fifty-ſix thouſand, nine hundred and eighty-ſeven millions, &c. &c. twelve, four hundred and fifty-ſix thouſand, nine hundred and eighty-ſeven million, &c. &c. And after this manner any other numbers, let the figures be what they may, are to be read.

Thus, 678075302, ſignifies ſix hundred and ſeventy-eight millions, ſeventy-five thouſand, three hundred and two; alſo, 20367540213, ſignifies twenty thouſand, three hundred and ſixty-ſeven millions, five hundred and forty thouſand, two hundred and thirteen.

N. B. It will be uſeful, in reading large numbers, to point them off at every three figures, as every three are run off together in the reading. Thus, in the laſt example, the firſt three are taken together, the next three are read in like manner, only the word thouſands is added; the next three are diſtinguiſhed by the word millions following in the reading. If there were three more, they would ſtill be read the ſame way, only the word thouſands would again follow; after the next three, millions of millions, (by ſome termed billions) after the next three, thouſands again; after the next, millions of millions of millions, (or trillions) and ſo on; the word thouſand, and the repetition of millions of millions of millions of millions, &c. or quadrillions, quintillions, &c. according to the value, following each other alternately in the reading.

The following is a Synopſis of the Roman Notation, by Letters of the Alphabet.

1	is denoted by	I	50=L
2	by	II	100=C
3		III	500=D or IƆ
4	IIII or	IV	1000=M or CIƆ
5		V	2000=MM
6		VI	5000=IƆƆ or $\overline{\text{V}}$
7		VII	6000=$\overline{\text{VI}}$
8		VIII	10000=$\overline{\text{X}}$ or CCIƆƆ
9		IX	50000=IƆƆƆ
10		X	60000=$\overline{\text{LX}}$
11		XI	
12		XII	100000=$\overline{\text{C}}$ or CCCIƆƆƆ
13		XIII	500000=IƆƆƆƆ
14		XIV	1000000=$\overline{\text{M}}$ or CCCCIƆƆƆƆ
15		XV	2000000=$\overline{\text{MM}}$
16		XVI	5000000=IƆƆƆƆƆ or $\overline{\text{IƆƆ}}$
17		XVII	10000000=$\overline{\text{CCIƆƆ}}$
18		XVIII	
19		XIX	50000000=$\overline{\text{IƆƆƆ}}$
20		XX	&c. &c.

Remarks on this Notation.

1ſt. As often as any character is repeated, ſo many times its value is repeated.

2d. A character of inferior value, with reſpect to another character, does, when placed before the ſame, diminiſh its value by the value of ſuch inferior character; but, if placed after it, the value thereof is ſo much increaſed.

3d. Every Ɔ affixed to this character IƆ (500) increaſes its value ten-fold.

4th. Every time a C and Ɔ are placed at each end of this character, CIƆ (1000) its value is increaſed ten-fold.

5th. A Line over any character increaſes its value a thouſand-fold.

By a ſlight compare of the two Notations, it is obvious how much ſuperior the preſent mode of numbering is to the old Roman method; both as being more ſimple and eaſy, and infinitely better accommodated to Arithmetical Operations.

The Characters or Signs made Uſe of in this Syſtem.

1ſt. This character (+) placed between two numbers, denotes that they are to be added together.

2d. This ſign (—) put between two numbers, ſhews that the latter is to be ſubtracted from the former.

3d. When this mark (×) is put between two numbers, it ſignifies that they are to be multiplied together.

4th. This character (÷) being between two numbers, denotes that the former muſt be divided by the latter.

Note alſo, if two numbers be placed one above another, with a line between them, it ſignifies that the upper number is to be divided by the under one.

5th. A figure of 2 put over any number, denotes the ſquare thereof, a figure of 3, the cube thereof, a figure of 4, the biquadrate thereof, &c. Thus, 4^2, 4^3, 4^4, denote the ſquare, cube, and biquadrate of 4, reſpectively.

6th. This ſign (√) prefixed to any number, ſignifies that the ſquare root thereof is to be extracted; and if a 3, 4, 5, &c. be put over this character, it ſhews that the cube, biquadrate, ſur-ſolid, &c. root, is to be extracted.

7th. When two points (:) are placed between two numbers, and four points (∷) between the next two, it indicates that theſe numbers are proportional. Thus, 2 : 4 ∷ 6 : 12, muſt be read thus: As 2 is to 4 ſo is 6 to 12.

8th. A line or vinculum (————) drawn over the top of numbers, ſhews that they are to be taken as one compound quantity.

ARTICLE II.

ADDITION OF WHOLE NUMBERS.

DEFINITION.

Addition is the method of collecting certain given numbers into one, which ſhall be equivalent to the whole.

AXIOM. The whole is equal to all its parts taken together. Hence this

RULE. Place all the numbers one under another, in ſuch order that the units place of each may exhibit one diſtinct row, the tens place of each another diſtinct row, the hundreds place another, the thouſands another, &c. drawing a line underneath the whole. Then begin at the unit's place, and reckon up all the figures in that row, writing down the overplus, above entire tens, under the line, and bearing in mind ſo many to be carried and added to the next row, as there are tens in the firſt. Then the row of tens, being accordingly added up, together with what was carried, the overplus which remains above entire tens, muſt be put down below the line, under the ten's place; and one for each ten muſt be carried to the next row, and the proceſs continued in this manner through each column; obſerving to write under the laſt row, the whole ſum.

N. B. When there is no exceſs above the tens, write a cypher under the column.

EXAMPLES.

3278	78426	40325
4152	54315	1072
673	67820	128
4028	47853	54320
7068	69542	7809
3254	57869	3456
782	34578	876
4630	78456	327
2043	47807	48728
Sum 29908	Sum 536666	Sum 157041

Here, in the firſt example, having placed the ſeveral ſums, one below another, and drawn a line under them, as directed above, I begin with the unit's column, ſaying 3 and 2 are 5, and 4 make 9, and 8, 17; and 8, 25; and 3, 28; and 2, 30, and 8, 38. I ſet down the overplus 8, and carry 3 for the three tens to the next column, which, on caſting up, I find amounts to 50; wherefore, as there is no overplus above the tens, I ſet down 0, and carry 5 to the next row, which I add up in like manner, and find it amounts to 29; I therefore ſet down 9, and carry 2 to the laſt row, the amount of which I find to be 29; I place down 29 accordingly, and ſo the whole ſum is 29908. Obſerve the ſame method in the other examples.

N. B. Addition is proved by beginning at the top and caſting each row downwards.

ARTICLE III.

SUBTRACTION OF WHOLE NUMBERS.

DEFINITION.

Subtraction is the taking of one number from another, in order to find their difference.

RULE. Place the greater number uppermoſt, ſo that units may be under units, tens under tens, &c. and draw a line under them. Then begin at the unit's place, and take the lower figure from the upper, placing down the difference underneath them; and do ſo with the reſt of the figures. But if the lower figure in any inſtance is greater than the upper, 10 muſt be added to the upper figure, and, ſubtraction being made, 1 muſt be carried to the next lower figure, and the ſum muſt be ſubtracted from the figure which is above the ſame, placing down the remainder, and proceeding agreeably to theſe directions with each row.

EXAMPLES.

From	4286	From	478023	From	678092
Take	3242	Take	67842	Take	589764
Remainder	1044	Remaind.	410181	Remaind.	88328

Here, in the firſt example, the numbers being properly placed, and a line drawn as directed, I proceed thus: Take 2 from 6 and there reſts 4, which I put down: then I ſay, take 4 from 8, and there reſts 4; take 2 from 2 and there reſts 0: and take 3 from 4 and there remains 1; each of which remainders I write down under its proper figure, and the whole is 1044.

In the ſecond example, I ſay 2 from 3 and there reſts 1; 4 from 2 I cannot take, but borrowing 10 to put to it, it becomes 12, from which taking 4, the remainder is 8; then I carry 1 to 8, and ſo it becomes 9; and as 9 cannot be ſubtracted from 0, I again borrow 10, and the remainder is 1; then I carry 1 to 7, and ſo ſubtracting, the remainder is 0. Alſo, 6 from 7, and there reſts 1, and nothing from 4 leaves 4; therefore the whole remainder is 410181: and ſo for any other.

N. B. Subtraction is proved by adding the remainder and the under line, or number ſubtracted, together; for, if their ſum be equal to the upper line, the work is right; otherwiſe not.

ARTICLE IV.

MULTIPLICATION OF WHOLE NUMBERS.

DEFINITION.

Multiplication is a compendious method of performing a manifold addition of the ſame number. But before any thing can be done, the following table muſt be perfectly got by heart.

MULTIPLICATION TABLE.

Explanation of the TABLE.

To find the Product of two figures, look for one of the figures in the top row, and for the other in the ſide row; then, in the angle of meeting is their Product.

Thus the Product of 5 and 8 is 40, and of 6 and 9 is 54.

1	2	3	4	5	6	7	8	9	10	11	12
2	4	6	8	10	12	14	16	18	20	22	24
3	6	9	12	15	18	21	24	27	30	33	36
4	8	12	16	20	24	28	32	36	40	44	48
5	10	15	20	25	30	35	40	45	50	55	60
6	12	18	24	30	36	42	48	54	60	66	72
7	14	21	28	35	42	49	56	63	70	77	84
8	16	24	32	40	48	56	64	72	80	88	96
9	18	27	36	45	54	63	72	81	90	99	108
10	20	30	40	50	60	70	80	90	100	110	120
11	22	33	44	55	66	77	88	99	110	121	132
12	24	36	48	60	72	84	96	108	120	132	144

General Rule for Multiplication.

Place the number (or number given to multiply by) under the multiplicand, (or the number to be multiplied) ſo that units may be under units, tens under tens, &c. and draw a line under them. Then begin with the unit's figure of the multiplier, (if it conſiſt of more than one) and by it multiply the unit's figure of the multiplicand. Set down the overplus above the tens, below the line, in the unit's place, and for each ten bear in mind 1 to be added to the next product. Then, by the ſame figure, multiply the next figure of the multiplicand, adding ſo many units as there were tens in the laſt product, and placing down the overplus as before. Proceed thus till each figure in the multiplicand has been multiplied by the firſt figure in the multiplier, writing down the product of the laſt entire. Then take the ſecond figure of the multiplier, and multiply thereby as with the firſt, placing the firſt figure of the product under the figure which you multiply with. Do ſo with each figure in the multiplier, ſo will the ſum of thoſe products be the Product required.

EXAMPLE I.

```
Multiply   468352
     By         6
          -------
Product   2810112
```

EXAMPLE II.

```
Multiply   6084358
     By         11
          --------
Product   66927938
```

EXAMPLE III.

```
Multiply     84308765
     By           243
          -----------
            252926295
           337235060
          168617530
          -----------
          20487029895
```

Here, in the firſt example, I multiply the firſt figure of the multiplicand by 6, ſaying 6 times 2 are 12; I ſet down the 2, and carry 1; then I proceed to the next figure, and ſay 6 times 5 are 30, and 1 that I carry, make 31; I ſet down 1, and carry 3, ſaying 6 times 3 are 18, and 3 make 21. I put down 1, and carry 2; proceeding to the next figure, whoſe product by 6 is 48, and 2 which are carried make 50; ſo I write down 0, and carry 5; then the product of the next figure is 36, and 5 which are carried, make 41; therefore, I place down 1 and carry 4; the laſt product is 24, and 4 which are carried make it 28, which I write down, and ſo the whole Product is 2810112.

In like manner the ſecond example is performed.

In the third example, I firſt multiply by 3, the unit's figure of the multiplier, ſetting down the whole Product 252926295, as above; then I multiply by 4, placing the firſt figure of the product directly under it, in the ten's place, and the reſt of the figures in the proper order as they follow each other. Laſtly, I multiply by 2, and place the firſt figure of the product under it in the third place, and the reſt in regular order as they come. Then the ſum of the products, caſt up in the order they ſtand, is 20487029895, which is the Product required.

Note. The ſecond example might have been done according to the manner of the third, by making two products, 1 being the multiplier each time.

EXAMPLE IV.

```
Multiply       42786307
     By          218403
          -------------
              128358921
          1711452280
           342290456
          42786307
         85572614
          -------------
Product  9344657807721
```

EXAMPLE V.

```
Multiply          68901478
     By            4567318
          ----------------
                 551211824
                68901478
              206704434
             482310346
            413408868
           344507390
          275605912
          ----------------
Product   314694960696004
```

COR. I. When either the multiplicand, multiplier, or both, have cyphers on the right hand, then multiply the ſignificant figures according to the former rule; and annex to the product as many cyphers as there are in the multiplicand and multiplier.

EXAMPLE. Let 8430876500 be multiplied by 243000.

Here, 84308765 multiplied by 243, the Product is 20487029895; to which annexing five cyphers (the number in both the multiplicand and multiplier) it becomes 2048702989500000, which is the Product required.

COR. II. Hence, if the multiplier be 10, 100, 1000, 10000, &c. the product is had by annexing as many cyphers to the multiplicand as there are in the multiplier. Thus the product of 246875 by 10 is 2468750; by 100, it is 24687500; by 1000, it is 246875000, &c.

COR. III. When the multiplier is a compoſite number, that is a number which conſiſts of complete factors, or in other words, is the product of ſome two or more numbers, then the multiplicand being multiplied by one of the factors, and that product by the other, and ſo on for each factor, the laſt product will be the product anſwering the whole; and by this method the trouble of adding two or more lines may frequently be ſaved.

EXAMPLE. Let 785364 be multiplied by 48.

Here the number 48 conſiſts of the factors 6 and 8. Whereſore I multiply 785364 by 8, and the product is 6282912, which multiplied by 6, gives 37697472, the anſwer ſought, and ſo the addition of two lines is ſaved.

N. B. It would have been the ſame if the firſt product had been made by 6, and the next by 8; for it is an indifferent thing in whatever order the factors are taken.

Alſo, in any numbers the multiplicand may be made the multiplier, and the multiplier the multiplicand, at pleaſure, according as it ſhall appear to be the moſt advantageous in the operation.

COR. IV. When the multiplier is any number above 10 and under 20, ſet the product made by the unit figure a place further to the right hand, and add thereto the multiplicand, or the multiplicand may be added by taking a figure at a time, as you proceed on in the operation after you have multiplied the firſt figure in the multiplicand.

EXAMP. Let 46302 be multiplied by 17. The operation is as below.

```
  Firſt Method.                Second Method.
46302                            46302
524114 Product by 7.                17
------                          ------
987134 Product.                 987134 Product.
```

Explanation of the Second Method.

Firſt, I multiply the unit's figure of the multiplicand by 7, and ſet down the overplus which is 4, and carry 1; then I multiply the next figure, or cypher, and take in the unit's figure of the multiplicand together with what was carried, and the whole is 3. Then I multiply the next figure which is 3, taking in the figure in the ten's place of the multiplicand; which in this inſtance, being only a cypher, does not augment the product. In like manner, I proceed to the next figure; the product thereby is 42, which, with 2 which was to be carried, and the figure in the hundreds place of the multiplicand, namely, 3 makes 47. I ſet down 7 and carry

4,

4, and thus proceed to the end, taking in a figure of the multiplicand each time. This, when it becomes familiar, is exceeding eaſy, and will ſave the writing of many needleſs figures.

N. B. In the ſame way when the multiplier is above 110, and leſs than 120, the product will be had by taking in the firſt figure of the multiplicand when you come to the ten's place, and the firſt and ſecond when you come to the hundred's place; afterwards the 2d and 3d, the 3d and 4th, and ſo on till the multiplication is compleated.

Cor. V. When the multiplier conſiſts of two figures and the unit's place is 1, multiply by the figure in the ten's place, and at each multiplication take in a figure of the multiplicand. The firſt figure ſo taken in muſt be that in the ten's place, the next that in the hundred's, &c. leaving out the unit's figure, but annexing the ſame to the product on the right, ſo that it may therein obtain the place of units.

Example. Multiply 634 by 21.

Here, in multiplying by 2, I take in 3 the firſt time, which makes the product 11, I ſet down 1 and carry 1, and the next time I take in the 6, which makes the product 13; I ſet down 3, and carry 1, and ſo the next product is 13, which I ſet down; and, by annexing the unit's figure to the number it becomes 13314, the product ſought.

634
21
13314

Cor. VI. When the multiplier is 100, 1000, 10000, &c. wanting any number conſiſting of two figures, of which either the firſt or ſecond figure is an unit, then multiply the multiplicand by the number ſo wanting; having previouſly annexed thereto, 2, 3, 4, &c. cyphers, as the caſe ſhall be, and the remainder will be the anſwer.

Thus let 54327 be multiplied by 988. Here the multiplier is 1000, wanting 12; therefore I multiply 54327, by 12, and the product is 6519324; which, ſubtracted from 54327000, leaves 53675076, the anſwer required.

Cor. VII. When in the multiplier, ſome two or more adjacent figures are equal to ſome multiple of another figure therein, the operation may be abbreviated by multiplying firſt by that other figure, and then that product by the figure which denotes the multiple, and adding the products together, having placed them ſo that the firſt figure of each row, or product, may ſtand under the firſt figure of thoſe in the multiplier, whoſe product, by the multiplicand, ſuch row denotes.

Example I.

Multiply 408765
By 3612
4905180
14715540
Product 1476459180

Example II.

Multiply 4675231
By 324981
42077079
378693711
1514774844
1519362245611

Explanation.

In the firſt example, I begin with multiplying by 12, and then I multiply that product by 3; becauſe, three times 12 are equal to the next two figures 36. I place the products down as above, and their ſum is the whole product required.

In the ſecond example, the firſt row of figures obtained, is the product by 9; the ſecond is taken equal to 9 times the firſt row; becauſe, 9 times 9, are equal to the firſt two figures (81), and the third row is taken equal to 4 times the ſecond row; becauſe, 4 times 81, are equal to the three laſt figures (324).

Their ſum, according to the due order in which they are placed, is 1519362245611, the product required.

In both theſe examples, the operations are performed with half the trouble and half the figures, which are required by the common method.

Schol. It will frequently happen that great advantages may be derived from the joint application of theſe ſeveral methods.

Thus. If the multiplier is 12816; the product for the firſt two figures, viz. 16, may be had in one line by Cor. IV. and the product for the laſt three will be had by multiplying that product by 8; becauſe 8 times 16, are equal to 128. And the product, by the whole, will be equal to the ſum of theſe two when placed in due order. This mode of contraction is not treated of by any author that I have read; nor, indeed, do I know of any perſon that has ever hit upon it, but myſelf.

Its uſe is very great, for it will ſeldom happen in the courſe of buſineſs but ſome advantage from it will accrue, either by rendering the operations ſhorter or more eaſy, or both; wherefore, I am happy in having the opportunity of communicating in the New Royal Encyclopædia, ſo uſeful an improvement in Arithmetical Calculations. A variety of foms of proceeding in different caſes might have been enumerated, but our limits confine me to paſs on to other matters; I am, however, perſuaded that what has been ſhewn, will prove a ſufficient leſſon to an ingenious mind.

ARTICLE V.

DIVISION OF WHOLE NUMBERS.

Definition.

As multiplication teacheth how to find the amount of any number when repeated a given number of times, ſo Diviſion, by having both the number and amount given, teacheth to diſcover how often ſuch number had been repeated in order to give that amount; or, by having, inſtead of the number, the number of times it was repeated, given; the number itſelf, (though, before unknown) is by this art found out.

Briefly, it is the art of finding ſuch a part of the dividend as the diviſor expreſſes; or, of diſcovering how often one number is contained in another.

General Rule. Set down the number to be divided (called the dividend) and the number by which the diviſion is to be made (named the diviſor) on the left hand thereof, but ſeparated from it by a crooked line. Alſo make another crooked line on the right hand, beyond which the figures ariſing by the diviſion (named the quotient) are to be placed.

Then take a part of the dividend, including as many figures to the left hand, as there are figures in the diviſor; or, one more, if the number expreſſed by them, when ſo taken, is leſs than the diviſor; and find how often the diviſor is contained in, or can be taken out of ſuch part of the dividend, (which generally may be diſcovered on a compare of the firſt, or two firſt figures of each) and place the figure which denotes the number of times in the quotient; obſerving to multiply the diviſor thereby, to ſubtract the product from the part of the dividend aforeſaid, and to note down the remainder.

Then annex to the remainder the next following figure in the dividend, and find how often the diviſor is contained in this number, (uſually called the dividual) placing the figure, which expreſſes the number of times in the quotient, and multiplying and ſubtracting as before.

Annex the next figure of the dividend to the remainder, and proceed again as above, continuing to do ſo, till all the figures of the dividend are in this manner brought into the operation.

N. B. When after a figure of the dividend has been annexed to a remainder, the number is leſs than the diviſor, a cypher muſt be placed in the quotient, and another figure of the dividend muſt be annexed; and the ſame muſt be repeated again, if the dividual is ſtill leſs than the diviſor.

Note alſo, That if after ſubtraction is made, the remainder is greater than the diviſor, the quotient figure has been taken too little, and muſt be ſo increaſed as to cauſe the remainder to be leſs than the diviſor.

Example I.

Divide 42674 by 26.
Divr. Divid. Quot.
26) 4264 (164
26
166
156
104
104
. . .

Example II.

Divide 378965 by 481.
Divr. Divid. Quot.
481) 378965 (787
3367
4226
3848
3785
3367
418 Remains.

Here in the firſt example, having placed the dividend and diviſor, as directed, I take the firſt two figures of the dividend, namely, 46, and enquire how often 26 is contained therein, and find it to be but once; I therefore place 1 in the quotient, and ſubtract 26 from 42, and the remainder is 16; to which I annex the next figure of the dividend, namely, 6; and ſo the dividual is 166. I now enquire how often 26 is contained in 166, and find it is contained ſix times; I place 6 in the quotient, and multiply the diviſor by 6, ſubtracting the product from 166; the remainder is 10, to which I annex the other figure of the dividend, namely, 4, and the dividual is conſeqnently 104. Again, I enquire how often the diviſor is contained in 104, and I find it is contained four times therein. I place 4 in the quotient, and multiply the diviſor thereby; the product is 104, therefore there is no remainder, and the whole quotient is 164.

The ſecond example is wrought in like manner, only in it there is a remainder after the diviſion is finiſhed of 418, which ſhews that the quotient is 787, and 418 parts out of 481 of another unit, viz. if 1 be divided into 481 parts, then the exact quotient is 787, and 418 of ſuch parts. Such parts are called fractions, and are expreſſed by placing the remainder over the diviſor, with a line between them, thus $\frac{418}{481}$. The upper number is named the numerator of the fraction, becauſe it expreſſes the number of the parts; and the lower number is called the denominator, becauſe, by it is underſtood of what denomination ſuch parts are. The whole quotient, therefore, will ſtand thus 787 $\frac{418}{481}$. But of fractions, and their operations, I ſhall treat hereafter.

Schol. When the diviſor is very large, and it appears that the quotient will conſiſt of a great many figures, it is adviſeable to multiply the diviſor by all the nine digits ſeverally, and place the products in a table, before one begins the operation, for by that means the quotient figure, as well as the product of it, and the diviſor, will always be had by inſpection, and ſo the buſineſs will conſiſt merely in ſubtracting.

Example. Divide 487654327861 by 246874.

Table.

246874	1
493748	2

```

Cor. I. When the diviſor does not exceed 12, it is unneceſſary to ſet down all the ſeveral products and ſubtract as has been taught, becauſe the proceſs at each figure may very well be comprehended in the mind without that trouble, and ſo as nothing in ſuch caſe is requiſite but to put down the quotient figures, it will make the work appear more conciſe and methodical to write them down under the dividend as they ariſe, a line of ſeparation having firſt been drawn.

Example I.

Divide 478654 by 6.

```
Diviſor.  Dividend.
     6 ) 478654
         ------
Quotient  79775 4/6
```

Example II.

Divide 68743254 by 11.

```
Diviſor.  Dividend.
    11 ) 68743254
         --------
Quotient  6249386 8/11
```

Here, in the firſt example, I aſk how oft 6 in 47, the anſwer is 7 times, for 7 times 6 is 42, and conſequently there remains 5, which is expreſſive of ſo many tens, and which carried to the next figure (8) of the dividend, they make 58; then I ſay, how oft 6 in 58? the anſwer is 9 times, and 4 remains, which carried to the next figure, they make 46; the ſixes in 46 are 7, and 4 remains; then the ſixes in 45 are 7, and 3 remains; and the ſixes in 34 are 5, and 4 remains, which I place over the 6 in manner of a fraction, and ſo the quotient is 79775$\frac{4}{6}$.

The other example is done after the ſame manner.

Cor. II. If the diviſor have cyphers towards the right hand, cut off ſo many of the right hand places of the dividend as there are ſuch cyphers in the diviſor; then, rejecting the cyphers in the diviſor, proceed to work as before; and, when the operation is finiſhed, annex the figures cut off to the remainder.

Thus, let the dividend be 46784, and the diviſor 300. I cut off two figures; viz. 84, from the dividend, and divide the reſt 467 by 3; the quotient is 155, and 2 remains; to which remainder I annex 85, the figures cut off, and it becomes 285, and ſo the quotient is 155$\frac{285}{300}$. The ſame muſt be obſerved for any other ſuch diviſor.

Cor. III. When the diviſor is 10, 100, 1000, 10000, &c. cut off ſo many figures to the right hand as the diviſor contains cyphers; then thoſe to the left will be the quotient, and the right hand figures will be the remainder.

Thus, let the dividend be 687543287, and the diviſor 1000; then three figures being cut off, the quotient is 687543, and the remainder 287; or the full quotient is 687543$\frac{287}{1000}$.

Cor. IV. When the diviſor is a compoſite number, that is, a number which is the product of two or more ſmall numbers, then divide by one of ſuch ſmall numbers, and that quotient by another, and ſo on till a diviſion has been made by each of them, and the laſt quotient will be the anſwer.

N. B. If there are remainders in the operation, multiply the laſt remainder by the laſt diviſor but one, taking in the remainder belonging to ſuch diviſor, (if any) then multiply that ſum by the laſt diviſor but two, and take in the remainder belonging to it, proceeding thus till you have multiplied by the firſt diviſor, and taken in the firſt remainder, (if any) and the reſult will be the remainder, anſwerable to the whole diviſor.

Example. Divide 47876 by 48.

Here firſt divide by 8, and the quotient is 5984, with a remainder of 4; then I divide this quotient by 6, and the next quotient is 997, with a remainder of 2. I multiply this laſt remainder by 8, taking in the firſt remainder, and the reſult is 20. So the true anſwer is 997$\frac{20}{48}$.

Schol. The beſt way of proving Diviſion is to multiply the quotient by the diviſor, taking in the remainder; and if the reſult be the ſame with the dividend, the work is right, otherwiſe not.

Alſo, the beſt way of proving Multiplication is by Diviſion; for if the product, when divided by the multiplier, give the multiplicand, the operation is true, otherwiſe it is not ſo.

The old method of proving Multiplication and Diviſion, by caſting out the nines, is not worth attending to, for it will often happen that the operation according to it will appear to be right, when the ſame is notwithſtanding wrong.

ARTICLE VI.

REDUCTION OF MONEY, WEIGHTS, MEASURES, &c.

Definition.

Reduction, properly ſpeaking, is not a Rule in Arithmetic, but is rather the application of Multiplication and Diviſion, in reducing money, weights, meaſures, &c. of any denomination to another. It includes three caſes.

Case I. If numbers of a greater denomination are to be reduced to their equivalents of a leſs, multiply continually by the number of the next inferior denomination which is equivalent to one of the greater, till you arrive at the required denomination, adding to each product, by the way, thoſe of the ſame denomination with itſelf, if ſuch there be, and the laſt product will be the anſwer. This is called Reduction Deſcending.

Case II. If numbers of a leſs denomination are to be reduced to their equivalents of a greater, divide continually by ſuch number as makes one of the next greater denomination, till you arrive at the required denomination, and the laſt quotient, with the ſeveral remainders, (if any) will be the anſwer. This is named Reduction Aſcending.

Case III. When a number of any propoſed denomination cannot be reduced to that required by Multiplication or Diviſion alone, both Rules are to be uſed promiſcuouſly; ſo that by one it may be reduced to ſuch a denomination as may by the other be reduced to the required denomination.

Note. When in Reduction Aſcending you have remainders, each will be of the ſame denomination with its reſpective dividend.

N. B. In this buſineſs, as well as in many of the following articles, it will be requiſite to have recourſe to Tables of Coin, Weights, Meaſures, &c. Such Tables will be given under their proper heads, namely, Coin, Weights, Meaſures, &c. and therefore it will be ſuperfluous to enumerate them here.

Example I.

Of Money. Descending.

In 32l. 14s. 6$\frac{1}{4}$d. how many farthings?

Operation.

```
        32   14   6¼
        20
       ---
       654 (adding 14)
        12
      ----
      7854 (adding 6)
         4
     -----
Anſw. 31419 (adding 3)
```

Example II.

Of Money. Ascending.

In 31419 farthings, how many pounds?

Operation.

```
 4 ) 31419
     -----
12 ) 7854 + ¼
     ---------
2|0 ) 65|4 + 6d.
      ---------
       32 + 14s.
     -------------
     32l. 14s. 6¼d.
```

Example III.

In 4674 crowns, how many guineas?

Operation.

```
  4674 crowns
     5 ſhillings in 1 crown
 -----
3)23370 ſhillings in all.
  -----
 7)7790
   ----
   1112 remainder 6.
Anſ. 1112 guineas and 18 ſhill.
```

Example IV.

In 1112 guineas and 18 ſhillings, how many crowns?

Operation.

```
Guineas. ſhillings.
  1112   18
    21
  ----
  1120 (taking in 8)
 2225  (taking in 1)
 -----
5)23370 number of ſhillings.
Anſ. 4674 crowns.
```

Example V.

In 3 cwt. 2 qrs. 14 lb. 10 oz. avoirdupoiſe, how many ounces?

Operation.

```
Cwt. qrs. lb. oz.
  3   2   14  10
  4
 --
 14
  28
 ---
 116
  29
 ---
 406
  16
 ----
 2436
 407
 ----
 6506 Anſwer.
```

Example VI.

In 420 gallons of beer, how many pints?

Operation.

```
 Gallons.
   420
     4
  ----
  1680 quarts.
     2
  ----
Anſw. 3360 pints.
```

EXAMPLE VII.

In 24 weeks how many minutes ?

24 weeks.
7
168 days.
24
672
336
4032 hours.
60
Anſw. 241920 minutes.

EXAMPLE VIII.

In 420 ells Engliſh, how many ells Flemiſh ?

420 ells Engliſh.
5
3) 2100 quarters.
Anſw. 700 ells Flemiſh.

EXAMPLE IX.

If 3 barley-corns make an inch, how many barley-corns will reach round the globe of the earth, ſuppoſing the circumference to be 360 degrees, and each degree to contain 70 Engliſh miles?

360 degrees.
70
25200 miles.
1760
1512000
428400
44352000 yards.
3
133056000 feet.
12
1596672000 inches.
3
Anſ. 4790016000 barley-corns.

ARTICLE VII.

ADDITION OF NUMBERS OF DIFFERENT DENOMINATIONS.

RULE. Place all numbers of the ſame denomination, directly under each other, obſerving to place the columns in ſuch order that the higheſt denomination may ſtand firſt towards the left hand, and the next inferior denomination next towards the right hand; and ſo on, that the loweſt denomination may obtain the farthermoſt place to the right hand, and draw a line under them. Then begin at the leaſt denomination; and add up all the figures in that row as in addition of whole numbers, and find by reduction how many of the next ſuperior denomination the ſum contains; carry the ſame to the next row, but writing down the overplus (if any) under the leaſt denomination, or the row which has been added.

Then add up the next row together with what was carried; finding, as before, how many of the next ſuperior denomination are contained in the ſum, in order to be carried to the next row, and writing down the overplus. Proceed in this manner till you come at the higheſt denomination, which muſt be added up and wrote down in all reſpects as in addition of whole numbers.

EXAMPLE I.

l.	s.	d.
241	14	6
123	10	4½
47	13	10¼
63	18	11
114	9	7½
57	16	0½
649	3	3¼

EXAMPLE II.

Troy Weight.

lb.	oz.	dwt.	grs.
47	11	15	14
14	9	13	15
71	10	10	10
67	10	15	17
81	9	10	18
12	10	4	0
297	2	10	2

EXAMPLE III.

Land Meaſure.

Acr.	Roods	Perch.
3	3	37
72	1	4
21	2	16
76	1	0
9	0	3
183	0	20

EXAMPLE IV.

Dry Meaſure.

Buſh.	Pecks	Gal.	Pts.
7	3	1	7
19	1	0	6
8	2	1	2
6	1	1	4
2	3	0	5
46	0	0	0

EXAMPLE V.

Cloth Meaſure.

Eng. Ells	Qr.	Nails
70	4	3
61	3	2
16	2	1
10	1	0
3	0	2
162	2	0

Here, in the firſt example, I begin and caſt up the column of farthings, and the ſum is 7, or 1 penny and 3 farthings; I ſet down ¾, and carry 1 to the row of pence; the amount of which I find to be 39, or 3 ſhillings and 3 pence. I ſet down the 3 pence, and carry 3 to the row of ſhillings, which I add up and find it amounts to 83, or 4 pounds 3 ſhillings. I put down 3 ſhillings, and carry 4 to the pounds, which I add up as in common addition. The whole ſum is 649l. 3s. 3¼d.

The reſt of the examples are equally eaſy, due regard being had to the different denominations, and how many of an inferior kind make one of the next ſuperior.

N. B. In order to facilitate the addition of money, ſome writers give what they call a Pence Table, in manner following.

PENCE TABLE.

d.		s.	d.	d.		s.	d.
20	is	1	8	130	is	10	10
30	—	2	6	140	—	11	8
40	—	3	4	150	—	12	6
50	—	4	2	160	—	13	4
60	—	5	0	170	—	14	2
70	—	5	10	180	—	15	0
80	—	6	8	190	—	15	10
90	—	7	6	200	—	16	8
100	—	8	4	210	—	17	6
110	—	9	2	220	—	18	4
120	—	10	0	230	—	19	2
				240	£	1	0 0

ARTICLE VIII.

SUBTRACTION OF MIXT NUMBERS, OR NUMBERS OF DIFFERENT DENOMINATIONS.

RULE. Place the leſs number under the greater, and in ſuch order as directed in addition; drawing a line under them. Then, beginning at the leaſt denomination, take the under numbers from the upper, and ſet down their reſpective remainders under them. But in caſe the under number of any denomination is greater than the upper, borrow one of the next ſuperior denomination, viz. add as many to the upper number as make 1, in the next higher denomination, and ſubtract as before, carrying 1 to the under line of the next ſuperior denomination, for that which was borrowed.

Note, the higheſt denomination muſt be ſubtracted as integers.

EXAMPLE I.

Money.

	l.	s.	d.
From	27	10	6½
Take	18	12	7¼
Rem.	8	17	11¼

EXAMPLE II.

Avoirdupoiſe Weight.

	Tons	cwt.	qr.	lb.	oz.	dr.
From	27	12	1	15	13	14
Take	18	16	2	13	15	15
Rem.	8	15	3	1	13	15

As our intention is to be brief, where much explanation is not required, I ſhall not enumerate further examples. Thoſe who underſtand one properly, will do any other with the ſame eaſe; and a due attention to the rule, together with what has been taught before, is amply ſufficient for the underſtanding of theſe examples.

ARTICLE IX.

TO MULTIPLY MIXT NUMBERS, OR NUMBER OF DIFFERENT DENOMINATIONS.

RULE. Place the multiplier under the number of the leaſt denomination, and having multiplied it, reduce the product to the next inferior denomination, ſetting down the overplus, and carrying the quotient to be added in the multiplying of the next row; proceed thus through each denomination.

N. B. When the multiplier is a compoſite number, multiply by the factors, as in multiplication of whole numbers.

Note alſo, if the number is above 12, and not compoſite, find the product for the neareſt compoſite number; then find the product for the exceſs, or defect, of the given number, and ſubtract it from, or add it to, the former product, (according as the caſe ſhall require) and the difference or ſum will be the anſwer ſought.

EXAMPLE I.

What is the value of 9 cwt. of ſugar, at

l. s. d.
4 17 11¾ per cwt.
9
£. 44 1 9¾ Anſwer.

EXAMPLE II.

What is the value of 12lb. of tea, at

s. d.
7 8½ per lb.
12
£. 4 12 6

EXAMPLE III.

What comes 100lb. of raiſins to, at 7½ per lb.

10
6 3
10
£. 3 2 6 Anſwer.

EXAMPLE IV.

What is the value of 37 dozen of knives, at

l. s. d.
2 5 7¾ per doz.
6
£. 13 13 10½
6
Val. of 36 doz. 82 3 3
Val. of 1 doz. 2 5 7¾
Anſwer £. 84 8 10¾

SCHOL. There are methods of obtaining the product in theſe caſes, let the multiplier be what it may, or however great; but in general, the trouble will be conſiderable, and the anſwer will be far more readily had by the RULE OF PRACTICE.

ARTICLE

ARTICLE X.
TO DIVIDE NUMBERS OF DIFFERENT DENOMINATIONS.

Rule. Divide each denomination beginning with the higheſt, as in diviſion of whole numbers; only obſerving, that when there is a remainder in any denomination, ſuch remainder muſt be reduced to the next inferior denomination, and added to the number of that denomination before the diviſion thereof takes place.

N. B. When the diviſor is a compoſite number, divide by the factors one after another, and the laſt quotient will be the anſwer.

Example I.

If 7lb. of ſugar coſt 5s. $1\frac{1}{2}$d. what is that per lb?

7) 5 $1\frac{1}{2}$
0 $8\frac{1}{2}$ Anſwer.

Example II.

Divide 44l. 1s. $9\frac{1}{4}$d. into 9 equal parts.

l. s. d.
9) 44 1 $9\frac{1}{4}$
£. 4 17 $11\frac{1}{4}$ = the value of each part.

Example III.

If 6l. 16s. 8d. be divided equally among 80 perſons, what is each man's ſhare?

l. s. d.
10) 6 16 8
8) 0 13 8
£. 0 1 $8\frac{1}{2}$ Anſwer.

Example IV.

Divide 27l. 3s. $4\frac{1}{2}$d. by 81.

l. s. d.
9) 27 3 $4\frac{1}{2}$
9) 3 0 $4\frac{1}{2}$
£. 0 6 $8\frac{1}{2}$ Anſwer.

Alike eaſy is the diviſion of Weights, Meaſures, &c.

ARTICLE XI.
VULGAR FRACTIONS.
Definitions.

1ſt. Fractions are expreſſions for any aſſignable parts of an integer or unit, and are repreſented by two terms, or numbers, placed one above another with a line between them; the upper term is called the Numerator, and the lower the Denominator, as was alſo noticed in Art. V. Likewiſe, the Denominator ſhews into how many parts the integer is divided, and the Numerator declares how many of ſuch parts are intended by the Fraction.

2d. A Proper Fraction is that where the Numerator is *leſs* than the Denominator, as $\frac{1}{4}$.

3d. An Improper Fraction is that wherein the Denominator is *leſs* than, or *equal* to, the Numerator; as $\frac{4}{3}$, or $\frac{3}{3}$.

4th. A Single Fraction is that which conſiſts but of *one* Numerator, and *one* Denominator.

5th. A Compound Fraction, or Fraction of a Fraction, is that whoſe parts are vulgar fractions connected with the word of, as $\frac{1}{2}$ of $\frac{2}{3}$, of $\frac{3}{4}$.

6th. A Mixt Number, is a Whole Number, with a Fraction annexed, as $15\frac{2}{3}$.

7th. The Reciprocal of a Fraction, is when the Numerator is changed into the Denominator, and the Denominator is made the Numerator. Thus $\frac{3}{2}$ is the reciprocal of $\frac{2}{3}$.

Hence, the reciprocal of a Proper Fraction, is an Improper Fraction, and *vice verſa*.

Lemma I. If the Numerator and Denominator of any Fraction be each multiplied, or divided by the ſame given number, the fraction, thus multiplied, or divided, retains its former value; thus, if the Numerator and Denominator of the fraction $\frac{1}{2}$, be multiplied by 2, it becomes $\frac{2}{4}$, which is equivalent to the former.

For, if any thing be divided into 2 parts, and one of them be taken, it is the ſame thing as if it were divided into 4 parts and two of them were taken; the value in each caſe being one half; and the ſame in diviſion, for if the Numerator and Denominator of the fraction $\frac{2}{4}$ be divided by 2, the fraction becomes $\frac{1}{2}$, which is equal to the former.

Lemma II. In any fraction, if the Numerator be augmented, or the Denominator, diminiſhed, its value in either caſe is encreaſed; but if the Numerator be made leſs, or the Denomitor, more, then its value is diminiſhed. Thus, ſuppoſe the fraction to be $\frac{3}{5}$, if the Numerator be augmented to 4, it is evident its value is augmented alſo; for, it is clear, that 4 parts out of 5, muſt be greater than 3 parts out of 5; or, if the Denominator be made 4, it is evident that the value is thereby increaſed; for 3 parts out of 4, are more than 3 parts out of 5; ſeeing, that when any number or quantity is divided only into 4 parts, each part muſt contain more than if the ſame were divided into 5 parts. By a ſimilarity of reaſoning, if the numerator is taken at 2, or the denominator at 6, its value is diminiſhed.

Heuce, alſo, if the Numerator of a fraction be multiplied by any given whole number, or the Denominator thereof divided thereby, the value of the fraction will be multiplied ſo many times as the given number expreſſes. Thus, if the Numerator of the fraction $\frac{1}{1}$, be multiplied by 3, it becomes $\frac{3}{1}$; or 3, which is equal to three times the former; or, if the Denominator of the fraction $\frac{3}{3}$, which, by the preceding Lemma, is equivalent to $\frac{1}{1}$, by divided by 3, it becomes $\frac{3}{1}$, as before; and ſo, in either caſe, its value is multiplied.

Alſo, by the like reaſoning, if the Numerator of any fraction be divided, or its Denominator multiplied by any given number, the value thereof will be diminiſhed ſo many times; or, which is the ſame thing, the value of the fraction will be thereby divided by ſuch number.

Note alſo, the Numerator of any fraction is expreſſive of a dividend, whereof the Denominator is the diviſor.

REDUCTION OF VULGAR FRACTIONS.

Prob. I. To reduce a whole number to the form of a fraction.

Rule. Place an unit (or 1) under it for a denominator.

Examp. Reduce 6, to the form of a fraction.

Here I place 1 under it, and it becomes $\frac{6}{1}$, the form required.

Schol. If it is required, that it ſhould have any aſſigned number for its Denominator, then multiply the Numerator and Denominator, of the form found as above, by ſuch number, and it will be the fraction required; for, by the preceding Lemma, it retains its ſame value. Thus, in the preceding Example, if it were required that its Denominator ſhould be 5, the fraction would be $\frac{30}{5}$.

Problem II. To reduce a fraction to its leaſt terms.

Rule. Divide the Terms of the given fraction by any number, which will divide them without a remainder, and the quotients (by the Lemma) will be the Terms of a new fraction, equivalent to the former; alſo thoſe terms, if they will divide by any number, muſt be divided, and ſo on, till a fraction is had; the terms of which cannot be divided by any given number, except unity, or 1, and then the fraction will be in its loweſt terms.

Examp. Let $\frac{10}{12}$ be propoſed. Here, by dividing both the terms by 2, we have $\frac{5}{6}$, which cannot be reduced lower, and ſo the fraction is in its leaſt terms.

Again, let $\frac{42}{72}$ be propoſed; then, by dividing by 2, we have $\frac{21}{36}$, and this being divided by 3, gives $\frac{7}{12}$, which is the fraction in its loweſt terms.

Cor. I. If the terms of any fraction conſiſt of numbers multiplied into one another, and expreſſed by the ſign of multiplication ($\times$) between them; then, if one number only in each term be divided by any given number, its value will remain the ſame, and it will be reduced into lower terms.

In like manner, if one number only in each term be multiplied, its value will be the ſame. And univerſally, if the ſame quantity of numbers in each term, thus connected, be multiplied, or divided, by any given number, the products, or quotients, will exhibit a fraction equivalent to the former.

Thus: let the fraction $\frac{3\times5\times4}{6\times10\times2}$ be propoſed. It is equivalent to $\frac{1\times5\times4}{2\times10\times2}=\frac{1\times1\times4}{2\times2\times2}=\frac{1\times1\times2}{1\times2\times2}=\frac{1\times1\times1}{1\times1\times2}=\frac{1}{2}$ in its leaſt terms.

Cor. II. It the terms of a fraction conſiſt of numbers connected by the ſigns of addition, (+) or of ſubtraction, (—) or both, then the numbers muſt either be reduced into one by means of addition and ſubtraction, in order to be reduced lower, or elſe every number in each term muſt be alike divided.

Example.

Let $\frac{4+6-2}{10+8-4}$ be propoſed. This is equal to $\frac{8}{14}=\frac{4}{7}$, the fraction in its leaſt terms; or the ſame is $=\frac{2+3-1}{5+4-2}=\frac{4}{7}$, as before.

Schol. In reducing fractions to their leaſt terms by the foregoing method, there will ſometimes be a great difficulty in finding ſuch a number as will divide both its terms; and then the method in the following Problem, of finding the greateſt common meaſure, is to be practiſed.

Problem III. To find the greateſt common meaſure of two or more numbers.

Rule. If there be two numbers only, divide the greater by the leſs, and the diviſor by the remainder, continuing to repeat the ſame till nothing remains; then will the laſt diviſor be the greateſt common meaſure required.

If there are three or more numbers, find the greateſt common meaſure for two of them; and then find the common meaſure of that common meaſure, and one of the other numbers; and ſo on through all the numbers; ſo will the greateſt common meaſure, laſt found, be the anſwer.

N. B. If 1 proves to be the common meaſure, the given numbers are prime to each other.

Example.

What is the greateſt common meaſure of $\frac{412}{516}$, or of 412 and 516?

Operation.

412) 516 (1
412
104) 412 (3
312
100) 104 (1
100
4) 100 (25
100
...

Here the diviſor, 4, is the greateſt common meaſure, and the fraction brought into its leaſt terms is $\frac{103}{129}$.

Problem IV. To find the leaſt number which can be divided by two or more given numbers without a remainder.

Rule. If the required number is only to be divided by two numbers, divide either number by the greateſt common meaſure, and multiply the quotient by the other number, and the product will be the anſwer.

If it is to be divided by three or more numbers, find the leaſt number which can be divided by two of them, and then find the leaſt number which will divide by that and another of the numbers, and ſo on through all the numbers; ſo will the number laſt found be the required anſwer.

Example.

What is the leaſt number which can be divided by 15 and 25?

Here the greateſt common meaſure is 5, and $25 \div 5 = 5$, and $15 \times 5 = 75$, the number ſought; or $15 \div 5 = 3$; and $25 \times 3 = 75$, as before.

Prob. V. To reduce a mixed number to an improper fraction.

Rule. Multiply the whole number by the denominator of the fraction, and to the product add the numerator; ſo will the ſum be the numerator of the required fraction; the denominator is the denominator of the given fraction.

Example. Reduce $5\frac{3}{4}$ to an improper fraction.

Here $5 \times 4 = 20$; and $\frac{20+3}{4} = \frac{23}{4}$, the fraction required.

N. B. This caſe properly belongs to addition of fractions, for it is the ſame thing as reducing the whole number to a fraction, whoſe denominator is 4 (as by Schol. of Prob. I.) and then adding the two fractions together, as directed in Article XI.

Problem VI. To reduce an improper fraction to its equivalent whole or mixed number:

Rule. Divide the numerator by the denominator, and the quotient will be the whole or mixed number required.

Example. Reduce $\frac{23}{4}$ to its equivalent whole or mixed number.

Here $23 \div 4 = 5\frac{3}{4}$, the anſwer.

Schol. As the numerator of any fraction is expreſſive of a dividend, and its denominator is the diviſor of ſuch dividend, the reaſon of the above proceſs is ſelf-evident.

Problem VII. To reduce a compound fraction to a ſingle fraction equivalent thereto.

Rule. Multiply together all the numerators of the given fractions: do the ſame with the denominators; then will the product of the former be the numerator, and of the latter the denominator of the fraction required.

Example. Let $\frac{2}{3}$ of $\frac{3}{4}$ be reduced to ſingle fraction.

Here $\frac{2\times3}{3\times4} =$ (in its leaſt terms) $\frac{1}{2}$, the fraction required.

Note. If any part of the compound fraction be a whole or mixed number, it muſt be reduced to a fraction by one of the former Problems, before this Rule is applied.

Schol. The reaſon of this rule is manifeſt; thus, in the above inſtance, the fraction $\frac{3}{4}$ is $3 \div 4$; and $\frac{2}{3}$ of $\frac{3}{4} = \frac{2}{3}$ of $3 \div 4$: but $\frac{2}{3}$ of 3 is 3 times greater than $\frac{2}{3}$ of 1 (or $\frac{2}{3}$) and, therefore, by the ſecond of the preceding Lemmas, $\frac{2\times3}{3} = \frac{2}{3}$ of 3; alſo $\frac{2\times3}{3} \div 4 = \frac{2}{3}$ of $\frac{3}{4}$, $=$ by the ſaid Lemma $\frac{2\times3}{3\times4} = \frac{1}{2}$, as before.

The rule may be proved in like manner for three or more fractions thus compounded, by taking the firſt two, and then the third, and ſo on.

Problem VIII. To reduce any fraction to another equivalent one, which ſhall have any aſſigned number for its denominator.

Rule. Multiply the numerator of the fraction by the aſſigned number; divide the product by the denominator, and the quotient will be the numerator of the fraction required, under which write the aſſigned number.

Example. Reduce $\frac{2}{3}$ to an equivocal fraction, which ſhall have 12 for its denominator.

Here $\frac{2\times12}{3} = 8$, the required numerator, and therefore the fraction is $\frac{8}{12}$.

Schol. The truth of this rule is manifeſt; for it is evident, that the numerator and denominator, by ſuch proceſs, will become equally multiplied or divided; and therefore the fraction ſo produced is (by Lemma 1) equivalent to the given fraction. Thus, in the above inſtance, if both terms of the fraction be multiplied by 4, it will give the required fraction.

N. B. When the numerator of the required fraction does not come out in whole numbers, the caſe is impoſſible.

Problem IX. To reduce fractions of different denominators to equivalent fractions having a common denominator.

Rule. Multiply all the denominators together, and it will be a common denominator for each fraction; to which denominator find the numerator of each fraction by the preceding Problem.

Example. Reduce $\frac{3}{4}$ and $\frac{5}{6}$ to a common denominator.

Here $4 \times 6 = 24$, the common denominator, then $\frac{3\times24}{4} = 3\times6 = 18$, the numerator for the firſt fraction; and $\frac{5\times24}{6} = 5\times4 = 20$, the numerator for the ſecond fraction; and therefore the required fractions are $\frac{18}{24}$ and $\frac{20}{24}$.

Schol. It is to be obſerved, that the above method, though it finds a common denominator, yet it does not find the leaſt common denominator, except when the denominators of the given fractions are prime to each other.

The leaſt common denominator is always the leaſt number, which will divide by each of the given denominators without a remainder, and is found by Problem IV; and the numerators anſwerable thereto will be found, as above, by Problem VIII.

In the laſt example, the leaſt number which can be divided by 4 and 6 is 12, and the numerators from thence for each fraction, are 9 and 10 reſpectively; and therefore the fractions, with the leaſt common denominator, are $\frac{9}{12}$ and $\frac{10}{12}$.

Problem X. To find the value of a fraction in the known parts of the integer.

Rule. Multiply the numerator by ſuch a number of units of the next leſs denomination as is equal to an unit (or 1) of that name or denomination which the fraction is of, dividing the product by the denominator, and the quotient ſhews the value ſought in ſuch inferior denomination.

If there be a remainder after the diviſion, multiply it by the number, which in the next inferior denomination conſtitute an unit, in the laſt or preceding denomination, and divide by the denominator as before, and the quotient will be the value of the remainder in ſuch inferior denomination. Proceed in this manner (if there are remainders after the diviſion) to the loweſt denomination, and the ſeveral quotients connected in due order will be the value of the whole given fraction.

Example I. What is the value of $\frac{3}{8}$ of a pound ſterling?

Here $\frac{3\times20s}{8} = 7s.$ with a remainder of 4; and $\frac{4\times12d}{8} = 6d.$ Wherefore the required value is 7s. 6d.

Example II. What is the value of $\frac{5}{6}$ of a cwt. avoirdupoiſe?

Here $\frac{5\times4\,qrs.}{6} = 3\,qrs.$ with a remainder of 2; and $\frac{2\times28\,lb.}{6} = 9lb.$ with a remainder of 2; and $\frac{2\times16\,oz.}{6} = 5\,oz.$ and a remainder of 2. and $\frac{2\times16\,drs.}{6} = 5\,drs.$ with a remainder of 2, (or $\frac{2}{6}$, or $\frac{1}{3}$.) And therefore the whole value is 3*qrs.* 9*lb.* 5*oz.* $5\frac{1}{3}$*drs.*

Example III. What is the value of $\frac{5}{8}$ of an acre?

Here $\frac{5\times4r.}{8} = \frac{5}{2} = 2r.$ with a remainder of 1. and $\frac{1\times40p.}{2} = 20p.$ And therefore the anſwer is 2 roods and 20 perches.

Problem XI. To reduce a fraction of one denomination to that of another.

Rule. If it be from a leſs denomination to a greater, multiply the denominator by all the numbers in each denomination, (from that given to that required) which make an unit in the next ſuperior denomination; but, if it be from a greater denomination to a leſs, multiply the numerator by all ſuch numbers of each denomination; and the product, in either caſe, will be the anſwer.

Example I. Let there be given $\frac{3}{5}$ of a penny, to find what fraction of a pound it is equivalent to.

Here $\frac{3}{5\times12\times20} = \frac{1}{5\times4\times20} = \frac{1}{400}$, the fraction ſought, in its leaſt terms.

Example II. Let there be given $\frac{3}{5}$ of a pound, to find what fraction of a penny is equivalent thereto.

Here $\frac{3\times20\times12}{5} = \frac{720}{5}$ of a penny, the anſwer $=$ 144 pence.

Example III. Reduce 12*s.* 6*d.* to the fraction of a farthing.

Here 12*s.* 6*d.* $=$ 150 pence $= \frac{150}{1}$ and $\frac{150\times4}{1} = \frac{600}{1}$, the fraction required.

Example IV. Reduce 7s. 6d. to the fraction of a pound.

Here 7s. 6d. $=$ 90 pence $= \frac{90}{1}$; and $\frac{90}{1\times12\times20} = \frac{9}{1\times12\times2} = \frac{3}{1\times4\times2} = \frac{3}{8}$, the fraction required.

Schol. Where broken numbers are given to be reduced to the fraction of any aſſigned integer, as in the two laſt examples, they muſt always be reduced to the loweſt denomination mentioned, and then turned into a fraction of that denomination (by writing 1 for its denominator, as taught in Problem I.) before the above Rule can be applied.

ADDITION AND SUBTRACTION OF VULGAR FRACTIONS.

Rule. Reduce compound fractions to ſingle ones, mixed numbers to improper fractions, fractions of different integers to thoſe of the ſame, and all of them to a common denominator.

This preparation being made, add together or ſubtract their numerators, as if they were whole numbers, and the ſum or difference will be the numerator fraction ſought; under which write the common denominator; then reduce the fraction to its leaſt terms, if it will admit of being brought lower.

Example I. Add together $\frac{1}{3}$ of a pound, $\frac{1}{2}$ of a ſhilling, and $\frac{1}{4}$ of a penny.

Here $\frac{1}{4}$ of a penny $= \frac{3}{4\times12\times20}$ of a pound $= \frac{1}{4\times4\times20} = \frac{1}{320}$; and $\frac{1}{2}$ of a ſhilling $= \frac{1}{2\times20} = \frac{1}{40}$ of a pound. So the given fractions are $\frac{1}{3}$, $\frac{1}{40}$, and $\frac{1}{320}$ of a pound. Which reduced to the leaſt common denominator become $\frac{320}{960}$, $\frac{24}{960}$, and $\frac{3}{960}$, reſpectively. Then $320+24+3=347$, the numerator ſought; and therefore the ſum of the given fractions is $\frac{347}{960}$ of a pound ſterling; which fraction is in its leaſt terms.

Example II. Subtract $\frac{1}{8}$ of a ſhilling from $\frac{1}{3}$ of $\frac{2}{5}$ of a pound.

Here $\frac{1}{8}$ of a ſhilling $= \frac{3}{8\times20} = \frac{3}{160}$ of a pound; and $\frac{1}{3}$ of $\frac{2}{5}$ $= \frac{1\times2}{3\times5} = \frac{2}{15}$ of a pound. Alſo $\frac{2}{15}$ and $\frac{3}{160}$ reduced to the leaſt common denominator, are $\frac{64}{480}$ and $\frac{9}{480}$ reſpectively. Their difference is $\frac{55}{480} = \frac{11}{96}$ of a pound, the anſwer.

MULTIPLICATION AND DIVISION OF FRACTIONS.

Rule. Reduce compound fractions to ſimple ones, and mixed numbers to improper fractions. Then, in multiplication, multiply the numerators together for a new numerator, and the denominators together for a new denominator. And, in diviſion, having, inſtead of the diviſor, ſubſtituted its reciprocal, proceed as in multiplication.

Example I. What is the product of $\frac{1}{2}$, $\frac{2}{3}$, and $\frac{2}{5}$, multiplied together?

Anſwer. $\frac{1\times2\times2}{2\times3\times5} = \frac{2}{3\times5} = \frac{2}{15}$.

Example II. What is the product of $\frac{2}{5}$ of $\frac{1}{4}$ of 7, muliplied by $\frac{3}{5}$ of 6?

Here $\frac{2}{5}$ of $\frac{1}{4}$ of $7 = \frac{2\times3\times7}{5\times4\times1}$; and $\frac{3}{5}$ of $6 = \frac{3\times6}{5\times1}$. This multiplied into the former, we have the anſwer $= \frac{3\times6\times2\times3\times7}{5\times5\times4} = \frac{3\times6\times3\times7}{5\times5\times2} = \frac{3\times3\times3\times7}{5\times5} = \frac{189}{25} = 7\frac{14}{25}$.

Example III. Let $\frac{4}{7}$ be divided by $\frac{2}{3}$.

Here the reciprocal of $\frac{2}{3}$ is $\frac{3}{2}$; and $\frac{4}{7}\times\frac{3}{2} = \frac{3\times4}{7\times2} = \frac{3\times2}{7} = \frac{6}{7}$, the anſwer.

Example IV. Divide $9\frac{1}{6}$ by $\frac{1}{2}$ of 7.

Here $9\frac{1}{6} = \frac{55}{6}$, and $\frac{1}{2}$ of $7 = \frac{7}{2}$; its reciprocal is $\frac{2}{7}$; and $\frac{55}{6}\times\frac{2}{7} = \frac{55\times2}{6\times7} = \frac{55}{3\times7} = \frac{55}{21} = 2\frac{13}{21}$, the anſwer.

Schol. The reaſon of the foregoing Rule will be underſtood from what follows.

Thus: let the firſt example be reſumed; then, to multiply the two firſt numbers together, $\frac{1}{2}$ and $\frac{2}{3}$, it is evident that $\frac{2}{3}$ is $=2\div3$, or the third part of 2; and therefore the product by 2 will be three times as great as that by $\frac{2}{3}$. Now, by Lemma II. the product by 2 is $\frac{1\times2}{2}$; but this, being three times as much as it ought, muſt be divided by 3; and, by the ſaid Lemma, a fraction is divided by any whole number, by multiplying the denominator; and therefore, $\frac{1\times2}{2\times3}$ is the product of $\frac{1}{2}$ by $\frac{2}{3}$; alſo, this product multiplied by $\frac{2}{5}$ is, for the ſame reaſon, $= \frac{1\times2}{2\times3}\times2$, and $\div5$; $= \frac{1\times2\times2}{2\times3\times5}$, which is agreeable to the Rule. Again, in diviſion, Example III. the diviſor, $\frac{2}{3}$, is = the third part of 2; and therefore, if $\frac{4}{7}$ be divided by 2, the diviſor, being = three times the proper diviſor, the quotient, of courſe, will be proportionably too little.

But $\frac{4}{7}\div2 = \frac{4}{7\times2}$; and this being multiplied by 3, gives $\frac{3\times4}{7\times2}$, as before, which proves the Rules true.

I have been the more copious on fractions, becauſe a due comprehenſion thereof is one main pillar in Arithmetic.

ARTICLE XII.

DECIMAL FRACTIONS.

Definitions.

1ſt. A decimal fraction is one which has an unit (or 1) for its denominator with cyphers annexed. Thus $\frac{1}{10}$, $\frac{2}{100}$, $\frac{3}{1000}$, &c. are decimal fractions.

d. A decimal fraction is expreſſed without the denominator, by writing only the numerator, and prefixing a point on the left hand of it; and the number of places in the numerator is always equal to the number of cyphers in the denominator. Thus .3 ſignifies $\frac{3}{10}$, .03 ſignifies $\frac{3}{100}$; $.37 = \frac{37}{100}$; $.004 = \frac{4}{1000}$; &c. conſequently, if the numerator has not ſo many places as the denominator has cyphers, the void places muſt be filled up with the cyphers towards the left hand.

3d. Cyphers on the right hand of a decimal do neither increaſe nor diminiſh its value. Thus, .3, .30, and .300, are equal to each other, becauſe $\frac{3}{10}$, $\frac{30}{100}$, $\frac{300}{1000}$, (which are their proper repreſentatives) are, as it is plain from vulgar fractions, equal to one another. But cyphers placed to the left hand, decreaſe the value of the fraction in a ten-fold ratio. Thus of the following; .3, .03, .003, &c. each one is in value but $\frac{1}{10}$ of the preceding one, as is evident from their repreſentatives in vulgar fractions; viz. $\frac{3}{10}$, $\frac{3}{100}$, $\frac{3}{1000}$, &c.

Schol. The reaſon of writing decimals thus is evident, for ſince they are equal to fractions, of like numerators with denominators, that are conſtantly 1 and cyphers annexed; and ſince the denominator of a fraction is a diviſor to the numerator, and to divide by 1, with cyphers annexed, is only to cut off ſo many figures as there are cyphers, the value of the fraction is fitly expreſſed by placing a point before the numerator. Thus: ſuppoſe the fraction $\frac{25}{100}$; now, ſince to divide by 100 is no more than to cut off two figures, therefore, when a point is put before .25, they will ſtand as figures cut off, or parts of 100.

Again: ſuppoſe the improper fraction $\frac{785}{100}$; it is plain they are $=7\frac{85}{100}$. But, according to the decimal notation, they muſt be expreſſed 7.85. And this notation, in many caſes, gives decimals a great advantage over vulgar fractions: for, as the ſeveral decimal parts are, as has been obſerved, in a ten-fold ratio, and the whole numbers alſo increaſe or decreaſe, in the ſame ratio, it follows that they may be promiſcuouſly brought into operation with each other, provided due care be uſed, and, at the concluſion, a proper number of figures be pointed off, anſwerable to the decimals that have been in uſe.

In what follows, I ſhall only lay down the Rules, with an example or two to each, leaving my reader to prove the truth of them by vulgar fractions.

REDUCTION OF DECIMALS.

Problem I. To reduce a Vulgar Fraction to a Decimal.

Rule. Annex as many cyphers to the numerator, as you would have decimal places, and divide by the denominator.

N. B. This is the ſame as finding the numerator of a fraction whoſe denominator is 1, with a given number of cyphers annexed. See Reduction of Vulgar Fractions. Prob. VIII.

Examp. I. Reduce $\frac{3}{8}$ to a decimal.

Here, If to 3 I annex 6 cyphers, as being deſirous, for the ſake of accuracy, of having ſo many decimals, then the quotient by 8 is .375000. But, as I find it comes without a remainder in three places of figures, I reject the three cyphers, as uſeleſs, for by definition 3, they are of no value.

Examp. II. Reduce $\frac{275}{3842}$ to a decimal. Anſwer .071577.

Schol. When it is requiſite that there ſhould be a great many places of decimals, and after a few figures are got, it is obſerved, that the remainder is either ſome multiple or aliquot part of the numerator of the given fraction; then multiply, or divide the figures already found (according as the caſe ſhall be) by the number, denoting ſuch multiple, &c. and the reſult will be the next following figures of the quotient.

Example. Let the fraction be $\frac{4}{17}$. Then, by proceeding as before, it will be found $=.235294\frac{2}{17}$, and the remainder 2, being $=\frac{1}{2}$ the numerator (4), I divide the ſaid quotient by 2, and the reſult is $117647\frac{1}{17}$; wherefore, I annex this to the former, and it becomes $.235294117647\frac{1}{17}$ true to 12 places of decimals. Again, I ſee that the remainder 1 is equal to $\frac{1}{4}$ of the numerator, and therefore by dividing the laſt quotient by 4, there will be 12 more places true, viz. $.058823529411\frac{13}{17}$, and this annexed to the former, gives $.235294117647058823529411\frac{13}{17}$. Alſo, I obſerve, that after the ſixteenth figure the decimal repeats the ſame figures again, and ſo it may be continued further at pleaſure, *ad infinitum.*

Problem II. To reduce the decimal of one denomination to the decimal of another.

Rule. This is performed in all reſpects as in common reduction, where one denomination is given to be reduced to another; obſerving, that there muſt be juſt as many places of decimals in the anſwer, as there are in the given decimal; and, therefore, when there are more places of figures in the anſwer than there are decimals in the given number, the exceſs to the left hand will be whole numbers; but if there are fewer places therein, the defect muſt be ſupplied by prefixing cyphers.

N. B. It will ſometimes be requiſite to annex cyphers to the given decimal, and then the number of decimal places muſt be taken accordingly.

Examp. I. Reduce .0235 of a pound ſterling, to the decimal of a penny. Here $.0235 \times 20 \times 12 = 52400$; and as the given number conſiſts of 4 places of decimals only, therefore, the anſwer is 5.2400, where 5 is a whole number, denoting ſo many pence, and the reſt .24 are decimal parts of a penny.

Examp. II. Reduce .2785 of a ſhilling to the decimal of a pound Here $.2785 \div 20$, (or which by definition 3 is the ſame $.278500 \div 20 =$) 13975; but the decimal places in the given number, with the cyphers annexed, are ſix, and therefore one cypher muſt be prefixed to this number; and ſo the anſwer is .013975 of a pound.

Corol. I. Hence the value of any decimal, in the ſeveral known parts of the integer, will be had by the ſame method; only obſerving, at each multiplication, to ſet off the whole numbers in each denomination, and continue the operation with the decimal parts only. Thus, if it is required to find the value of .3785 of a pound ſterling, in ſhillings, pence, &c.

Here $.3785 \times 20 = 7.5700$ (the 7. being ſhillings); then $.57 \times 12 = 6.84$, (the 6. being pence) and $.84 \times 4 = 3.36$, (the 3. being farthings) and ſo the value is 7s. $6\frac{1}{4}$d. and .36 decimal parts of a farthing.

Again, In 342.5 pence, how many pounds?

Here 342. pence = 1l. 8s. 6d. and .5 of a penny = $\frac{1}{2}$, and therefore the required value is 1l. 8s. $6\frac{1}{2}$d.

Corol. II. Any integer number of an inferior denomination, is brought to the decimal of a ſuperior denomination, by reducing it firſt to the vulgar fraction of ſuch ſuperior denomination, and then finding its equivalent decimal by **Problem I.** or, a ſufficient number of cyphers being annexed thereto for decimal places; it may often be more conveniently reduced to the decimal of ſuch ſuperior denomination, by dividing, as directed in this Problem; obſerving, to make as many decimal places in the anſwer, as there were cyphers annexed in the operation, by prefixing as many cyphers as are neceſſary.

Example. Reduce 9d. to the decimal of a pound. Here $9 \div 12$, or, which is the ſame, $9.00 \div 12 = .75$; and $.75 \div 20$; or, $.7500 \div 20, = .0375$, the decimal required.

Corol. III. Hence, if the given number conſiſts of integers in divers denominations, to be reduced to the decimal of ſome ſuperior denomination; reduce the loweſt denomination to the next ſuperior, and prefix thereto the given integers of that denomination. Alſo reduce that number to the decimal of the next ſuperior denomination, prefixing the integers, if any, as before, and ſo on to the end. The laſt reſult is the anſwer.

Example. Reduce 5s. $3\frac{1}{4}$d. to the decimal of a pound. Here 1 farthing, reduced to the decimal of a penny, is .25, to which I prefix 3, and it becomes 3.25; and this reduced to the decimal of a ſhilling is .2708333, &c. and prefixing 5, it is 5.2708333, which reduced to the decimal of a pound is .263541666, &c. the anſwer.

N. B. The ſeveral denominations of Weights, Meaſures, &c. are managed in like manner; due regard being had to the number of integers which in one denomination is equivalent to an unit in the next ſuperior denomination, as was ſhewn both in reduction of whole numbers and vulgar fractions.

Schol. The value of any decimal of a pound ſterling, may be had by inſpection, thus: Double the firſt figure (or that in the place of tenths) for ſhillings, and if the ſecond figure be 5, or more, reckon another ſhilling; then call the figures in the ſecond and third places, after the 5 is deducted, ſo many farthings, abating 1 when they are above 12, and 2, when above 37; and the reſult will be the anſwer.

Example. What is the value of .375 of a pound?

Here the double of 3 is 6, but the next figure being above 5, I make it 7, which are ſhillings. Then the reſidue (when 5 is taken from 7) is 25; which, being above 12, I reckon only 24, for farthings, which make 6d. and ſo the value required is 7s. 6d.

ADDITION AND SUBTRACTION OF DECIMALS.

Rule. Reduce the decimals to one and the ſame denomination, if they are not ſo already. Then place the numbers ſo, that the units (if any) may ſtand under units; and the tenth's place of the decimals, under the tenths, &c. and add or ſubtract them as in whole numbers, placing each figure directly under its proper column, ſo that it may obtain the ſame place in the rank of decimals, &c. as the figures in ſuch column obtain.

MULTIPLICATION AND DIVISION OF DECIMALS.

Rule. Multiply and divide them as in whole numbers; obſerving in Mulplication, that the product muſt contain as many places of Decimals, as there are in both the multiplicand and multiplier; and in Diviſion that the number of ſuch places, in the quotient, together with thoſe in the diviſor, muſt be equal to the number of decimal places in the dividend.

Hence, if the dividend be a whole number, or contain but few places of decimals, cyphers muſt be annexed thereto, till the number of decimal places therein exceed the number of ſuch places in the diviſor, by as many as there are decimal places required in the quotient.

Example I.		Example II.	
Mult.	4.276	Mult.	.57324

21304
14380
10652
37282
37282
5

Here, in the ſecond example, the product contains only 8 figures, though, according to the rule, there ſhould be 9 decimal places; wherefore I prefix a cypher to make up a deficiency, placing a point before it, to ſhew that the figures are decimals.

In the fourth example, the dividend being a whole number, and the diviſor having two decimal places, I annex two cyphers (as decimals) to the dividend; and then, according to the Rule, all the figures in the quotient are whole numbers; but if there had been a remainder after the diviſion, and it had been required to have a certain number of decimals in the quotient, then as many cyphers more muſt have been annexed as would have been equal to the required number of decimals.

In the laſt example it appears, that, without annexing cyphers there ſhould be five places of decimals in the quotient; and therefore I find it requiſite to prefix a cypher. There being a remainder of 5, more places of decimals may be had by annexing cyphers.

Thus, by annexing 6 cyphers, the quotient will be .04270000938. But, if the quotient is continued no farther than .04270, the cypher on the right hand may be rejected; for in that caſe, by Definition III. it does not augment the value.

Cor. I. If any decimal number is to be multiplied by 10, 100, 1000, &c. the product will be had by only removing the decimal point ſo many places towards the right hand, as there are cyphers annexed to the unit; and, on the contrary, if the diviſor of any decimal number is 10, 100, 1000, &c. the quotient will be had by removing the decimal point the like number of places towards the left hand. Thus; $.2754 \times 100 = 27.53$; and $387.54 \div 100 = 3.8754$.

Cor. II. When, in multiplication, there are many decimal parts in the multiplicand and multiplier, and but a few decimals are required in the product, the operation may be ſhortened, as follows:

Write the unit's place of the multiplier under that figure in the multiplicand, whoſe place you would retain in the product, diſpoſing the reſt of the figures in the contrary order to that which they are properly placed in; then begin always at that figure in the multiplicand which ſtands over the figure which you multiply with, and ſet down the products, ſo that their right hand figures may ſtand in a line under one another.

Note. The firſt figure in every line muſt be increaſed with what would ariſe (by carrying 1, from 5 to 15; 2 from 15 to 25; 3 from 25 to 35, &c.) from the product of the preceding figures which are left out of the operation.

Example I.	Example II.
Multiply 79.80625 by 7.854, and let four places of decimals be retained in the Product.	Multiply 535.5625 by .6375, and let three decimals be retained.
Operation.	Operation.
79.80625	535.5625
458.7	5736.0
5586438	321338
638450	16067
39903	3749
3192	268
Product 626.7983	Product 341.422

N. B. In the ſecond example, there being no unit's figure in the multiplier, therefore, to render the operation the more plain and eaſy to be comprehended, according to the Rule, I have put a cypher in the place of units.

Cor. III. By a ſimilar procedure, the operations in diviſion may be ſhortened. The method is thus: conſider, according to the foregoing Rule, how many decimal places there ought to be in the dividend, in order to give the deſired number of decimals in the quotient; alſo, conſider how many figures the quotient (with ſuch number of decimals) will contain, which is done by obſerving how many figures of the dividend will be uſed (according to the common method) to give the firſt quotient figure; then each of the remaining figures of the dividend will give a figure more. Take as many of the left hand figures of the diviſor into the operation, as there are to be figures in the quotient, and as many figures of the dividend as will give the firſt quotient figure; and at each diviſion leave out another figure on the right hand of the diviſor, always making the laſt remainder the dividend.

Example. Let 63092.878 be divided by 76.84375, and let there be three places of decimals in the quotient.

Operation.

Diviſor. Dividend.
76.84375)63092.87|8(821.054
6147500
161787
153688
8099
7684
415
384
31
31
..

Here, in this example, there being five places of decimals in the diviſor, there ought, (according to the common method) to be eight places of decimals in the dividend, in order to give three decimal figures in the quotient; and therefore, to the dividend there ſhould be five cyphers annexed. Alſo, it is evident, that to give the firſt quotient figure (by the whole diviſor) will take all the given figures of the dividend; and as the five cyphers will give five more figures, it is plain that there will be ſix figures in the quotient. Therefore I take only ſix figures of the diviſor, with as many of the dividend as will give the firſt quotient figure.

In each diviſion I leave out another figure of the diviſor, but augment its product by each quotient figure, as was taught in multiplication.

RULE OF PRACTICE.

Definition.

Practice is a compendious way of caſting up the value of any articles, whether by Weight or Meaſure, the price of the integer being given.

It is in general formed by taking ſuch aliquot parts of the given quantity, as the price is of a pound, ſhilling, &c.

The following are the moſt uſual methods.

1ſt. When the price is leſs than a penny, divide by the aliquot parts of a penny, and then by 12 and by 20, and you will have the value required.

2d. When the price is an aliquot part of a ſhilling, divide by ſuch aliquot part, and the quotient will be the anſwer in ſhillings; which, if above 20, muſt be reduced into pounds.

3d. When the price is pence and farthings, and not an aliquot part of a ſhilling, divide the given number by ſome aliquot part of a ſhilling; and then conſider what part of the ſaid aliquot part the reſt is, and divide the quotient thereby; and the laſt quotient, together with the former, will be the anſwer in ſhillings, which muſt be reduced into pounds as before; or the price may frequently be ſo divided, that each part will be ſome aliquot part of a ſhilling, and then a proper aliquot part of the given number muſt be taken for each, and their ſum collected as above.

4th. When the price is an even number of ſhillings, without pence and farthings, multiply the given number by the half thereof; doubling the firſt right hand figure of the product for ſhillings, and thoſe to the left are pounds.

5th. When the price is any odd number of ſhillings, except 5, either multiply thereby and divide by 20, or find the value of the greateſt even number, as above; to which add $\frac{1}{20}$ of the given number, for the odd ſhilling.

6th. When the price is an aliquot part of a pound, as 10s. 6s. 8d. 5s. 4s. &c. divide the given quantity by ſuch aliquot part, and the quotient will be the anſwer in pounds.

7th. When the price is ſhillings, pence, &c. it muſt be ſo divided, that one or more of the foregoing rules may be applied, as ſhall appear moſt convenient; and when it can be done, aliquot parts of parts may be taken.

8th. When the given number is a whole number, with parts annexed, find the value of the whole number by the preceding methods; to which add a part of the price anſwerable to the given parts.

9th. When the given quantity, whoſe value is ſought, is of ſeveral denominations; and the price is of an integer of the higheſt denomination, multiply the price by the number of the higheſt denomination, or find the value thereof by ſome of the foregoing methods; then take the ſame parts of the price for thoſe of the lower denominations, as they are of an unit of the higheſt denomination, and the ſum of all will be the anſwer.

10th. When the given quantity is of ſeveral denominations, and the price is that of an unit of ſome lower denomination, the higher denominations muſt be reduced to ſuch lower denomination; and then the laſt, or ſome preceding method, muſt be uſed.

TABLE OF ALIQUOT PARTS.

Parts of a Pound.

1qr. is ¼ | 11 3 val. of 1qr of cwt
£. 144 11 3 Anſwer.

OF TARE AND TRETT, &c.

Definitions.

1ſt. **Tare** is an allowance to the buyer of any commodity for the weight of the box, caſk, &c. containing the ſame.

2d. **Trett** is an allowance of 4lb. in every 104lb. on account of waſte, duſt, &c.

3d. **Cloff** is an allowance of 2lb. upon every 3cwt. to make the weight hold out when retailed.

4th. **Gross Weight** is the whole weight both of package and goods before any of the aforeſaid allowances are deducted.

5th. **Suttle Weight** is when part of the allowances are deducted from the groſs.

6th. **Neat Weight** is that which remains after all the allowances are deducted.

The Rules for making theſe allowances are reſolved into the five following caſes.

I. When Tare only is allowed, and the ſame is ſo much in the whole, Subtract it from the groſs, and the remainder will be the Neat Weight.

II. When the Caſe is as before, but the Tare is at ſo much per box, caſk, &c. multiply the number of boxes, caſks, &c. by the Tare of one of them, Subtract the product from the groſs, and the remainder will be the Neat Weight.

III. When the Caſe is as before, but the Tare is at ſo much per cent. Divide the groſs weight by the aliquot parts of a cwt. as in the Rule of Practice; ſubtract the quotient (or the ſum or difference of the quotients, as the caſe ſhall be) from the groſs, and the remainder will be the Neat Weight.

IV. When both Tare and Trett are allowed, Divide the Suttle Weight (or that weight which remains after the Tare is deducted) by 26; ſubtract the quotient from the ſubtle, and the remainder is the Neat.

V. When Tare, Trett, and Cloff are allowed, Deduct the Tare and Trett as above directed, and divide the Suttle by 168; then ſubtract the quotient from the Suttle, and the remainder will be the Neat Weight.

EXAMPLES.

I. Let the Groſs be 28 cwt. 2 qrs. 18 lb. and the Tare 1 cwt. 1 qr. 21 lb. 8 oz. required the Neat Weight?

Here, 1 cwt. 1 qr. 21 lb. 8 oz. ſubtracted from the Groſs, leaves 27 cwt. 0 qr. 24 lb. 8 oz. the Neat Weight required.

II. What is the Neat Weight of 7 hogſheads of tobacco, each weighing 5 cwt. 2 qrs. 21 lb. Groſs, and the Tare 98 lb. per hogſhead?

Here, 5 cwt. 2 qrs. 21 lb. multiplied by 7, gives 39 cwt. 3 qrs. 7 lb. the whole Groſs; and 98 lb. or 3 qrs. 14 lb. multiplied by 7, gives 6 cwt. 0 qr. 14 lb. the whole Tare, which ſubtracted from the Groſs, leaves 33 cwt. 2 qrs. 21 lb. the Neat Weight required.

III. Let the Groſs be 16 cwt. 2 qrs. 14 lb. and the Tare 16 lb. per cwt. what is the Neat Weight?

Here, 16 lb. is $\frac{1}{7}$ of a cwt. Wherefore, divide the Groſs by 7, and the quotient, 2 cwt. 1 qr. 14 lb. is the Tare, which ſubtracted from the Groſs, leaves 14 cwt. 1 qr. the Neat Weight.

IV. Suppoſe the Groſs Weight to be 154 cwt. 2 qrs. 8 lb. and the Tare 10 lb. per cwt. what is the Neat Weight, allowing alſo for Trett?

OPERATION.

Cwt. 2 qrs. is $\frac{1}{2}$ | 10 lb.

16 lb. is $\frac{1}{7}$ | 154 8 lb. is $\frac{1}{7}$ of 2 qrs. $\frac{1}{7}$ | 5 oz.

4 is $\frac{1}{4}$ of 16 $\frac{1}{4}$ | 22 qrs. 7$\frac{1}{2}$ nearly

5 2 Tare of 2 qrs. 8 lb. 5 7$\frac{1}{2}$

16 2 = tare of 154 cwt.

5 lb. 7$\frac{1}{2}$d tare 2 qrs. 8 lb.

16 2 5 7$\frac{1}{2}$ whole tare.

	Cwt.	qrs.	lb.	oz.	
Groſs	154	2	8	0	
Tare	16	2	5	7$\frac{1}{2}$	
26)	138	0	2	8$\frac{1}{2}$	Suttle
	5	1	6	9	nearly = Trett
Anſw.	132	2	23	15$\frac{1}{2}$	Neat Weight

V. What is the Neat Weight of two hogſheads of tobacco, each weighing 5 cwt. 3 qrs. 20 lb. Groſs, the Tare being 7 lb. per cwt. and the Trett and Cloff as uſual?

OPERATION.

	Cwt.	qrs.	lb.	
	15	3	20	
			2	
	31	3	12	groſs.
7 lb. is $\frac{1}{16}$	1	3	26$\frac{1}{4}$	tare.
26)	29	3	13$\frac{3}{4}$	
	1	0	16$\frac{1}{4}$	nearly, trett.
168)	28	2	25$\frac{1}{2}$	ſuttle.
	0	0	19	cloff.
Anſw.	28	2	6$\frac{1}{2}$	Neat Weight.

N. B. In ſome commodities 2 lb. in 100 lb. is allowed for Cloff, in which caſe, inſtead of dividing the Suttle by 168, it muſt be divided by 50 only, and the quotient will be the Cloff to be ſubtracted as before.

Note alſo, that in calculating oil, if the Neat Weight be reduced into half pounds, and divided by 15, the quotient will be the neat Gallons, becauſe 7$\frac{1}{2}$ lb. are allowed to the gallon.

SINGLE RULE OF THREE.

DEFINITIONS.

1ſt. This Rule takes its name from having always, in the queſtions to which it relates, three terms given to find a fourth, which ſhall have the ſame proportion to one of the given terms as ſubſiſts between the other two; it is therefore ſometimes called the Rule of Proportion; and, becauſe of its excellence and uſe, it is alſo named the Golden Rule.

2d. Before the operation is begun, the given terms muſt be arranged in one line, with two points between the 1ſt and 2d, and four points between the 3d and 4th. Thus, 2 : 4 : : 6; and the reading of them is after this manner; viz. as 2 is to 4, ſo is 6 to the fourth number or anſwer. When the fourth term is found (or given) it is frequently ſet after the third term, with two points between them.

3d. To arrange the terms properly, is called ſtating the queſtion; to perform which, obſerve that the term, whereon the demand of the queſtion reſts, is to be made the ſecond term; it is generally preceded by the interrogative of the queſtion; viz. the words, I demand? How much? How many? How long? What will? &c.

The firſt term is always of the ſame kind, or nature, as the ſecond; and the third is of the ſame kind, or nature, as the fourth term or anſwer.

4th. When the 4th term or anſwer bears ſuch proportion to the 3d as the 2d does to the 1ſt, the queſtion is called Direct; which is the caſe when there is the ſame affection between the 3d and 4th, as there is between the 1ſt and ſecond; viz. when the 2d term is either greater or leſs than the firſt; and it is neceſſary that the 4th be in like manner either greater or leſs than the 3d.

5th. When the 4th term bears ſuch proportion to the 3d as the 1ſt does to the 2d, the queſtion is ſaid to be Inverſe; the affection between the 3d and 4th being, under ſuch circumſtance, of a contrary nature to the affection between the 1ſt and 2d. This happens when the 2d term is either greater or leſs than the firſt; and it is neceſſary, that the fourth be in the former caſe leſs, and in the latter greater than the 3d.

Having by theſe inſtructions ſtated the queſtion, and diſcovered from its nature whether the ſame be direct or inverſe, then to perform the operation, obſerve the following rules.

I. Reduce the 1ſt and 2d terms to one and the ſame denomination, if they are not ſo already; and the 3d term to the loweſt denomination, if it be a number of ſeveral denominations.

II. If the queſtion be direct, multiply the 2d and 3d terms together, and divide the product by the firſt, and the quotient will be the anſwer in the ſame denomination with the 3d term, after its reduction, if any was made.

III. If the queſtion be inverſe, multiply the 1ſt and 3d terms together, and divide the product by the 2d, and the quotient will be the anſwer, as before.

N. B. Sometimes when the 3d term is of ſeveral denominations, it will be unneceſſary to reduce it to the loweſt, viz. when the 1ſt and 2d terms are ſuch, that the Multiplication and Diviſion may be eaſily performed without it.

Note alſo, when the given terms are fractions, the reciprocal of the firſt and ſecond term, according as the queſtion is Direct or Inverſe, may be taken in lieu of ſuch term, and then the anſwer will be had by multiplying all the terms together.

EXAMPLE I. If 5 oxen coſt 55 l. 10 s. what will 21 oxen coſt at that rate?

	oxen.		oxen.		l.	s.		
As	5	:	21	: :	55	10	(:	the Anſwer)
						20		
						1110	ſhillings.	
						21		
					5)	23310	product of 2d and 3d terms.	
					2|0)	466|2	anſwer in ſhillings.	
						£233	2s. anſwer in pounds.	

EXPLANATION. The demand of the queſtion in the above example, is the value of 21 oxen? therefore, by Definition 3d, 21 oxen muſt be the ſecond term; then as (by the ſaid Definition) the firſt term muſt be of the ſame kind or nature with the ſecond, it is plain that 5 oxen muſt be the firſt term; and the other number, namely 55 l. 10 s. which is of the ſame nature with the anſwer, muſt be the third term; wherefore I write them down in order as above, and the proper reading thereof in that order is, as 5 is to 21, ſo is 55 l. 10 s. (the price of 5) to the anſwer (or the price of 21.) Then, to determine whether the queſtion be Direct or Inverſe, I obſerve, that the ſecond term is greater than the firſt, and the anſwer muſt be greater than the third, in the ſame proportion; and therefore (by Definition 4th) the queſtion is Direct.

Then, according to Rule I. I reduce the third term into ſhillings; alſo I multiply the ſame by the ſecond term, and divide the product by the firſt, and the quotient is the anſwer in ſhillings, according to Rule III. which, being divided by 20, gives the anſwer in pounds.

SCHOLIUM I. In order to abbreviate the operations, it will be convenient to connect the two terms, which are to be multiplied together with the ſign of multiplication between them, and to write the diviſor under them in manner of a fraction, which will be a fractional expreſſion for the anſwer, to be reduced into its loweſt terms by Prob. II. of Fractions.

SCHOL. II. Sometimes alſo the operation may be ſhortened thus: obſerve how often that term which is the diviſor is contained in one of the other terms (noting the Remainder) and multiply the remaining term by the quotient, and take parts for the remainder, to be added to the product.

SCHOL. III. When the diviſor is a compoſite number, and one of the other terms is leſs than the diviſor, but no aliquot part thereof, obſerve what aliquot part of the diviſor comes neareſt to the ſaid leſs term; divide the remaining term by the number denoting the aliquot part, and it will give the value, anſwering to the number expreſſed by the ſaid aliquot part of the diviſor. Then take aliquot parts of this value for the exceſs or defect, and ſubtract or add the ſame, as the caſe ſhall be, and it will give the anſwer.

Contractions of this kind will often prove extremely uſeful, though they have not, I believe, been noticed by any other author. Thus the preceding Example may, by Scholium I. (after the reduction) be written, $\frac{1110\times 21}{5}$ = anſwer in ſhillings, and $\frac{1110\times 21}{5\times 20}$, or $\frac{1110\times 21}{100}$ = anſwer in pounds $= 11.10\times 21 =$ 233.1 l. or 233l. 2s.

Or, by following the ſecond Scholium, I obſerve that 5 is contained 4 times in 21, but that there is a remainder of 1. Therefore I multiply 55l. 10s. by 4, and it gives 222l. to which I add the fifth part of 55l. 10s. viz. 11l. 2s. (becauſe 1 is the fifth part of 5) and the ſum is 233l. 2s. as before.

Note. In following this method, when the remainder is large, it will be better to take the quote 1 more, and ſo deduct, inſtead of adding, a proportionable ſhare, anſwerable to the parts in exceſs.

Thus, in the foregoing example, if the ſecond term had been 24, then the neareſt quote, by the firſt term, would have been 5, but producing an exceſs of 1. Therefore, in that caſe, I ſhould have multiplied the 55l. 10s. by 5, and deducted a fifth part from the product, in order to obtain the anſwer.

Example II. Suppoſe a ſhip ſails 24 leagues in 12 hours, (or half a natural day) how many leagues will ſhe ſail in a week, at the ſame rate?

Hours. Week. Leag.

Here the ſtating will be thus: As 12 : 1 : : 24 (: the anſwer.) But as in 1 week there are 14 half days, therefore, when the firſt and ſecond terms are reduced to the ſame denomination, the proportion will be, As 1 : 14 : : 48 : Anſwer.

And $\frac{14\times 24}{1} = 336$ leagues, the diſtance ſought.

Example III. If 9 yards of cambric coſt 5l. 12s. what will 72 yards coſt at that rate?

Yds. yds.
As 9 : 72 : : 5l. 12s. (Anſwer.)

Therefore the anſwer $= \frac{5\text{l. }12\text{s.}\times 72}{9} = 5\text{l. }12\text{s.}\times 8 = 44\text{l. }16\text{s.}$

Example IV. If 8 men can finiſh a piece of work in 15 days, what number of men will be requiſite to perform the ſame in 24 days?

Days. Days. Men.
As 15 : 24 : : 8 : Anſwer.

Here the proportion is Inverſe, becauſe the ſecond term is greater than the firſt; and the anſwer muſt be leſs than the third; for it is not neceſſary to have ſo many men to do a piece of work, if 24 days be allowed, as would be employed, provided 15 days only were allowed.

Therefore, $\frac{8\times 15}{24} = \frac{15}{3} = 5$, the number of men required.

Example V. If 56 yards of ſhalloon, of 3-quarters wide, are neceſſary for the linings of 10 ſuits of cloaths, how many yards of ſhalloon, of 5-quarters wide, would it take to line them?

Qrs. Qrs. Yards.
As 3 : 5 : : 56 : (Anſwer.)

Here the queſtion is alſo Inverſe; and therefore, $\frac{3\times 56}{5} = 56 \times .6 = 33.6$ yards $= 33\frac{3}{5}$ yards = the Anſwer: or $\frac{3\times 56}{5} = 3 \times 11\frac{1}{5} = 33\frac{3}{5}$, as before.

Example VI. If $\frac{3}{16}$ of a ſhip coſt 274l. 12s. 6d. what will $\frac{5}{32}$ thereof be worth?

As $\frac{3}{16}$: $\frac{5}{32}$: : 274l. 12s. 6d. : Anſwer.

Therefore, $\frac{16}{3} \times \frac{5}{32} \times$ 274l. 12s. 6d. = Anſwer; viz. $\frac{16\times 5}{3\times 32}$ (or $\frac{5}{2\times 3} = \frac{5}{6}$) $\times$ 274l. 12s. 6d. $= \frac{274\text{l. }12\text{s. }6\text{d.}\times 5}{6}$ $= 45\text{l. }15\text{s. }5\text{d.}\times 5 = 228\text{l. }17\text{s. }1\text{d.}$ the Anſwer.

Or, the two fractions reduced to the leaſt common denominator are $\frac{6}{32}$ and $\frac{5}{32}$; and rejecting the denominators, as common to both multiplier and diviſor, the proportion will ſtand thus. As 6 : 5 : : 274l. 12s. 6d. : (Anſwer.) And 274l. 12s. 6d. $\times$ 5 = 1373l. 2s. 6d. which, divided by 6, gives 228l. 17s. 1d. the ſame as before.

Example VII. If 60 gallons of water, in 35 minutes time, be conveyed through a pipe into a ciſtern which holds 200 gallons, and if, by a cock in the ciſtern, there runs out 45 gallons in the ſame time, how long will the ciſtern be in filling, provided the cocks keep running at the above rates?

Here it is evident, that, at the end of 35 minutes, there will be 15 gallons in the ciſtern, and that it will keep filling at the ſame rate.

Gal. Gal. Min.
Hence, As 15 : 200 : : 35 : (Anſwer.)

Therefore, $\frac{200\times 35}{15} = \frac{200\times 7}{3} = \frac{1400}{3} = 466\frac{2}{3}$ minutes, or 7 hours, 46 minutes, and 40 ſeconds, the Anſwer.

Example VIII. If 54 oxen coſt 411l. 1s. 6d. what is the price of 20 oxen at that rate?

Oxen. Oxen.
As 54 : 20 : : 411l. 1s. 6d. : (the Anſwer.)

OPERATION.

$$\begin{array}{r|rrr} 3\,) & 411 & 1 & 6 \\ \hline 9\,) & 137 & 0 & 6 \\ & 15 & 4 & 6 \\ \hline £ & 152 & 5 & 0 \end{array} \text{ Anſwer.}$$

Here I divide the price by 3, and it gives the price of 18, becauſe 18 is the $\frac{1}{3}$ part of 54. Then, to obtain the price of the remaining 2, I divide this by 9, becauſe 2 is the $\frac{1}{9}$ part of 18. The ſum of theſe is 152l. 5s. the Anſwer ſought.

Other queſtions might be given to illuſtrate this Rule, but a due attention to what has been delivered, will afford ſufficient inſtruction for every caſe, and in a more conciſe and methodical method than has been given by other writers.

DOUBLE RULE OF THREE.

The Double Rule of Three, by ſome called the Rule of Five, is when five terms are given to find a ſixth.

The beſt method of ſolving queſtions of this kind, is to make two ſtatings in the ſingle rule; but to ſuſpend the operation till it is diſcovered from the nature of the queſtion, which terms will be multipliers, and which diviſors.

Then the three terms which are multipliers, may be connected by ſigns of multiplication between them, and the two terms which are diviſors may be connected in like manner, and written under the other with a line between them, in form of a fraction, to be reduced to its leaſt terms, as has been ſhewn in the ſingle rule. And in general all the contractions, which have been introduced there, may be occaſionally uſed here.

Example I. If the carriage of 100lb. weight for 30 miles coſt 2 ſhillings, what will the carriage of 500lb. coſt for 200 miles?

As 100lb. : 500lb. : : 2s. : (1ſt Anſwer.)
As 30m. : 200m. : : 1ſt Anſwer : (Anſwer required.)

Then $\frac{500\times 2\times 200}{100\times 30} = \frac{50\times 2\times 2}{3} = \frac{200}{3} = 66\text{s. }\frac{2}{3} = 3\text{l. }6\text{s. }8\text{d.}$ = the Anſwer.

Explanation. Here I ſay by the ſingle rule as 100lb. is to 500lb. ſo is 2s. the value of the carriage of 100lb. for 30 miles, to the value of 500lb. for 30 miles.

Then, as 30 miles is to 200 miles, ſo is the firſt anſwer (or the value of 500lb. for 30 miles) to the value of 500lb. for 200 miles.

The firſt anſwer by the ſingle rule $= \frac{500\times 2}{100}$; and the ſecond Anſwer therefore $= \frac{500\times 2}{100} \times 200 \div 30 = \frac{500\times 2\times 200}{100\times 30}$ as above.

Or, ſince from the nature of the queſtion, both the ſtatings are direct; therefore the firſt terms of each are diviſors, and the reſt multipliers; and hence the procedure is evident.

This mode is vaſtly ſuperior to that of working out the firſt ſtating by itſelf, not only becauſe there will be frequently a remainder in the firſt operation, which, if neglected in the ſecond, will ſometimes produce a material error in the required anſwer, or, if retained, will make the work very troubleſome and tedious, but, becauſe conſiderable advantages will often occur in this way, which cannot poſſibly happen in the other.

Example II. If 68 men can build a wall in 27 days, when the day is 9 hours long? in how many days will 54 men build the ſame when the day is 17 hours long?

Men Men Days
As 68 : 54 : : 27 : (1ſt Anſwer.)
Hours Hours
9 : : 17 : : 1ſt Anſwer (to true Anſwer.)

Then $\frac{68\times 27\times 9}{54\times 17} = \frac{4\times 9}{2} = 2\times 9 = 18$ days, the Anſwer.

Here both the ſtatings are inverſe; for, in the firſt ſtating, it is evident, that 54 men muſt require a longer time for the doing of a piece of work than is neceſſary, in caſe 68 men are employed; and therefore the fourth term, or anſwer, muſt be greater than the third, and of courſe will not have the ſame affection to it, as the ſecond has to the firſt.

In the ſecond example it is plain, that when the day is 17 hours long, a piece of work will be done in fewer days, than when the day is only 9 hours long; and therefore the fourth term, or the required anſwer, muſt be leſs than the third term; or the time that 54 men can do a piece of work in, when the day is 9 hours long, ſuppoſed to be obtained by the firſt ſtating.

Wherefore, this ſtating is alſo inverſe; and therefore 54 and 17, are the diviſors, and the reſt multipliers.

This queſtion is called a queſtion of the Double Rule of Three inverſe. Sometimes one ſtating will be direct, and the other inverſe, and ſuch queſtions are alſo deemed inverſe; wherefore, ſince there is ſuch a difference in queſtions of this kind, this mode of ſolution which diſcovers at once what ſtatings are direct, and which are inverſe, muſt be infinitely preferable to that ambiguous way (uſed by many authors) of placing all the five terms in one line, after a certain order; and then giving rules for operation, according as the queſtion is conceived to belong to the direct or inverſe rule; without conſidering whether an inverſe queſtion involves two indirect ſtatings, or only one.

Example III. If 24 ſtudients ſpend 64 pounds in 16 months, what ſum of money will ſerve 9 ſtudients 8 months?

ſtu. ſtu. l.
As 24 : 9 :: 64 : (1ſt Anſwer.)
m. m.
As 16 : 8 :: 1ſt Anſwer : (required Anſwer.)

Then $\frac{9\times64\times8}{24\times16}=\frac{9\times4}{3}3\times4=12$l. the Anſwer.

Schol. Sometimes queſtions will occur wherein 3 or more ſtatings are neceſſary, but the ſame method may be applied to all.

Example IV. If the carriage of 150 feet of wood, that weighs three ſtone per foot, comes to 3l. for 40 miles, how much will the carriage of 54 feet of free ſtone, that weighs eight ſtone per foot come to for 25 miles?

Feet feet l.
As 150 : 54 :: 3 : (1ſt Anſwer.)
Stone ſtone
As 3 :: 8 : 1ſt Anſwer. : (2d Anſwer.)
Miles miles
As 40 : 25 :: 2d Anſwer. : (required Anſwer.)

Then $\frac{54\times3\times8\times25}{150\times3\times40}=\frac{54}{6\times5}=\frac{9}{5}=1\frac{4}{5}$l. $=$ 1l. 16s. the Anſwer ſought.

Here all the ſtatings are direct, as is evident on inſpection, and therefore 150, 3, and 40, are the diviſors, and the reſt multipliers.

Schol. Sometimes the given numbers will be ſuch as cannot be reduced at once to an anſwer, by this method of placing them in a fractional manner; but it will, nevertheleſs, be convenient to expreſs them ſo at firſt, as they will be a guide to the future operation, and in moſt caſes ſome advantages may be derived from it.

N. B. It is in this, as in the ſingle rule, commonly neceſſary to reduce the 1ſt and 2d terms of each ſtating to one and the ſame denomination; and the third term (unleſs the reſt of the numbers are ſuch, that the operation may be performed without that trouble) muſt be reduced to the loweſt denomination mentioned in it.

ARTICLE XII.

INVOLUTION AND EVOLUTION.

Definitions.

I. If a number be multiplied certain times into itſelf, the reſult is called a power of that number.

When a number is multiplied into itſelf once, the reſult is called the 2d Power; when twice, the 3d Power; thrice, the 4th Power; and ſo on; the number itſelf being always deemed the 1ſt Power, though uſually named the Root.

The 2d Power is alſo called the Square, the 3d, the Cube, the 4th, the Biquadrate, the 5th, the Sur-ſolid, the 6th, the Square Cube, &c. of any number.

Corol. Hence, if it be required to find any Power of a given number, it is done by multiplying the ſame as often into itſelf as is denoted by the number of the Power, leſs 1.

Thus, the 3d Power of $16=16\times16\times16=4096$; the 4th Power thereof $=16\times16\times16\times16=65536$; and ſo for any Power of any other number.

Definition II. The raiſing of a given number to any required Power, is called Involution; but if a certain Power of any number be given, and it be required to determine the 1ſt Power thereof, or the number or root from which the ſame was raiſed, then the art of performing this buſineſs is called Evolution, or the Extraction of Roots; and on this I ſhall ſolely inſiſt through the following part of this Article.

Note. The Root of the 2d Power is called the Square Root; of the 3d Power, the Cube Root; of the 4th Power, the Biquadrate Root, &c.

TABLE OF POWERS.

1ſt Power or Root.	2d Pow or ſquare	3d Pow. or Cube	4th Pow. or Biqua.	5th Pow. or Sur-ſolid.	6th Pow. or ſquare Cube.	7th Pow. or 2d Sur ſolid.	8th Pow. or ſquare Cube.	9th Pow. or Cube Cube.
1	1	1	1	1	1	1	1	1
2	4	8	16	32	64	128	256	512
3	9	27	81	243	729	2187	6561	19683
4	16	64	256	1024	4096	16384	65536	262144

To Extract the Square Root.

Rule I. Diſtinguiſh the given number into periods of two figures each, by putting a point over the place of units, another over the place of hundreds, another over the place of tens of thouſands, &c. Alſo, if there are decimals, by placing a point alſo over the hundredths plaae, another over the ten thouſandths place, &c. annexing a cypher, if requiſite, to make the periods complete. Then there will be as many figures in the Root as there are periods; and the periods of decimals denote the number of decimals in the Root.

II. Find by the Table a ſquare number, either equal to, or the next leſs than the firſt period to the left hand, and put the root of it to the right hand of the given number, in manner of a quotient, and it will be the firſt figure of the root required.

III. Subtract the ſquare number, found as above, from the firſt period, and to the remainder bring down the next period for a reſolvend or dividend; and, on the left thereof, write the double of the quotient figure for a diviſor; and ſee how oft it is contained in the reſolvend (excluding the laſt figure).

IV. Annex the anſwer to the quotient figure, and alſo to the diviſor, multiplying the ſame, thus augmented, by this laſt quotient figure, and ſubtracting the product from the whole reſolvend.

V. Then to the remainder bring down the next period, for a new reſolvend; double the whole quotient for a diviſor, annexing thereto the next figure of the root, and thus proceed unto the end; obſerving, that if at any time the product of the laſt quotient figure, and the augmented diviſor, be greater than the reſolvend, a leſs figure muſt be taken in lieu thereof, and placed in the quotient.

Note. If after all the figures in the dividend have been brought into the operation, there ſhould ſtill be a remainder, and it is required that the anſwer ſhould be had to a greater degree of accuracy, then annex a pair of cyphers to the remainder, and proceed to find another figure, (which will be a decimal) do the ſame to the next remainder, and ſo on, till there are as many decimal figures in the root as is requiſite.

Note, alſo, That when half the deſired number of figures are had in the root, the reſt may be found by dividing by the double of the root (according to the ſhort method of leaving out a figure in the diviſor each time) without being at the trouble of obtaining new diviſors, or annexing to the remainders any more periods of figures. And it is further obſervable, that inſtead of doubling the root each time for a diviſor, the laſt quotient figure may all along be added to the former diviſor.

Example I.

What is the ſquare root of 327286.9681?

Operation.

```
                         Root.
    327286.9681 ( 572.09
    25
 107)772
   7 749
 ----------
 1142)2386
    2 2284
 ----------
114409) 1029681
        1029681
        -------
        .......
```

Example II.

What is the ſquare root of 10?

Operation.

```
 10.000000(3.16227
  9
61)100
 1  61
------
626)3900
  6 3756
--------
 632)14400
      1264
      ----
       176
       127
       ---
        49
        44
        --
         5
```

Here, in the firſt example, I point off the given number into pairs, both ways from the unit figure (6). Then I find that the greateſt ſquare number under 32 is 25, which I place under 32, and the root 5 in the quotient, doubling the ſame for a diviſor. Then bring the next period (27) down for a dividend, and perceive that the next quotient figure will be 7, which I therefore annex to the root, and to the diviſor, placing the product of the whole diviſor by 7 under the dividend, ſubtracting it therefrom, and bringing down the next period. Then I add the laſt quotient figure to the former diviſor, (or, which is the ſame, double the whole quotient) and it becomes 114. I obſerve that the next figure in the root will be 2, which I annex to the diviſor, and to the quotient; and thus I proceed to the end, and find the root 572.09.

The ſecond example is wrought in like manner, only there, after three figures are had, I divide by the double of the quote; and, as I do not include the laſt root figure, I cut off one figure from the laſt period brought down, and ſo, with very little trouble, I obtain three more figures. If, in the laſt diviſor, I had included the quotient figure, I ſhould then have got four figures more in the root.

Schol. The ſquare root of a vulgar fraction is found by extracting the ſquare root of the numerator for a new numerator, and the ſquare root of the denominator for a new denominator. Thus the ſquare root of $\frac{4}{9}=\frac{2}{3}$. The truth of this is evident, for $\frac{2}{3}$ ſquared $=\frac{2}{3}\times\frac{2}{3}=\frac{4}{9}$; or, if it is deſired that either the numerator or denominator of the root ſhall be the ſame as that of the given fraction, then multiply the numerator and denominator together, and extract the ſquare root of the product, which will be the reſpective denominator or numerator of the required root.

Thus, in the former example, if it is required that the numerator of the root ſhould be the ſame as that of the given fraction, namely, 4.

Then, $4 \times 9 = 36$, the ſquare root of which is 6; and $\frac{4}{6}$ is the fraction required: or, if it is required to have the ſame denominator, then $\frac{6}{9}$ is the root required. The truth of this proceeding is evident; for $\frac{4}{6}$, and $\frac{6}{9}$, are each $= \frac{2}{3}$ the former root; or, it may be proved thus; $\frac{4\times4}{9\times4} = \frac{4}{9}$; and therefore the ſquare root of $\frac{4\times4}{9\times4}$ is of courſe $=$ ſquare root of $\frac{4}{9}$.

Alſo, $\frac{4\times9}{9\times9} = \frac{4}{9}$; and therefore the ſquare root of $\frac{4\times9}{9\times9} =$ ſquare root of $\frac{4}{9}$.

In the former caſe, the ſquare root of the numerator is equal to the given numerator, and in the latter, the ſquare root of the denominator is equal to the given denominator.

This method, therefore, will ſave the extraction of one of the terms of the given fraction. However, in general it will be better to reduce the given fraction to a decimal, and then extract its root.

TO EXTRACT THE CUBE ROOT OF A GIVEN NUMBER.

Rule I. Point off the given number into periods of 3 figures each, placing a point over the unit's figure, and one upon every 3d figure, both to the right and left thereof, if there are decimal figures in the given number.

II. Find the greateſt cube contained in the firſt period, and ſubtract it therefrom, placing the root in the quotient, and annexing the next period to the remainder for a Reſolvend.

III. Divide the ſaid reſolvend (excepting the two laſt figures of the period annexed) by three times the ſquare of the quotient figure, which will generally give the next figure of the root, though ſometimes, in this firſt inſtance, it will prove too big.

IV. Having placed the figure in the quotient, multiply the ſame by thrice the firſt figure of the root, and write the product under the diviſor before uſed; in ſuch order, that the ten's place thereof may ſtand under the unit's place of the other; alſo ſquare the laſt figure, and place this under the product, ſo that the ten's place (if any) may ſtand under the unit's place of the product; ſo will the ſum of the three rows in the order they ſtand, be a more correct diviſor.

V. Divide the whole of the above reſolvend by this diviſor, and to the remainder bring down the next period.

VI. Divide this (leaving out the two laſt figures as before) by 3 times the ſquare of the root, already found, and place the figure in the quotient, adding to ſuch diviſor, the product of thrice the laſt mentioned root, by this figure, together with the ſquare of the ſaid figure; but placed in the ſame order as is deſcribed above, for finding the laſt correct diviſor; then the ſum will be another correct diviſor.

VII. Divide the laſt reſolvend by this diviſor, and to the remainder bring down the next period, proceeding to find another figure of the root, and a correct diviſor as before, and ſo on to the end; when, if there be ſtill a remainder, and more exactneſs be required, annex to the remainder three cyphers, and repeat it till as many decimal figures are obtained as is requiſite.

Example. What is the cube root of 67507.82424?

Operation.

```
                                   Root
                    67507.824240 (40.717
                    64
      3 × 4² = 48)  3507 Reſolvend

    3 × 40² =    4800 \
   7×3×40  =      840  )3507824 Reſolvend
       7²  =       49  )3419143
     Diviſor    48889 /

   3 × 407² = 496947  \
 1 × 3 × 407 =   1221   )  88681240 Reſolvend
      1 × 1 =       1   )  49706911
     Diviſor 49706911 /

   3 × 4071² = 49719123  \   38974329000 Reſolvend
7 × 3 × 4071² =    85491  )  34809370813
        7² =          49  )   4164958187 Remainder.
     Diviſor  4972767259 /
```

Here by annexing more cyphers, and continuing the operation, the anſwer may be had to any degree of accuracy. But when a few figures are got, as many more may be had true in the root without changing the diviſor; and there need not to be more figures taken in the diviſor, than there are figures already in the root, and a figure may be cut off each time as has been before taught, which renders the work exceeding ſhort.

Thus, in the above example, having the laſt reſolvend 38974329000, the diviſor 4972767259, and 40.71 the root, there may be cut off from the diviſor and dividend, ſix figures each, and four more figures will be had correct in the root, with very little trouble; as follow,

```
  Diviſor   Reſolvend
4972|767259)38974|329000(7817
  ...       34809|
            4165
            3978
              87
            . 50
              37
              35
               2
```

The 4 figures obtained as above, being annexed to 40.71, make the root 40.717817, true to 8 figures, and the laſt 4 being obtained with great facility.

N. B. If the firſt 4 figures of thrice the ſquare of the root had been uſed for the diviſor, it would have been ſufficient; at leaſt, it would give three more places correct, and not have differed from the truth above 1 in the fourth figure.

A general Method of extracting the Roots of all Powers.

Rule I. Prepare the given number for extraction, by pointing it off from the unit's place into periods; each of which muſt contain as many figures as is denoted by the number, expreſſing the name of the power.

II. Find the firſt figure of the root by trial, take the difference between the power thereof, from the given number, and to the remainder bring down the firſt figure belonging to the next period for a dividend.

III. Involve the root to the next inferior power to that which is given, and multiply it by the number, denoting the given power for a diviſor.

IV. Find how many times the diviſor may be had in the dividend, and the quotient will be another figure to be added, or ſubtracted to the root, according as the former was leſs or greater than the truth.

V. Involve the whole root to the given power; take the difference between it and the given number, and annex thereto the firſt figure of the next period for a new dividend; finding a diviſor as before, and proceeding thus till the operation is finiſhed.

N. B. When a few figures are had in the root, the next diviſor will give near as many more, without the trouble of renewing the operation.

Example. What is the biquadrate root of 19987173376?

Operation.

```
                          .  .  .
                     19987173376      / 4 . . Root too great
                4⁴=256........       (  —2 .  leſs, quote
                Diff. 5612826624     (   38 .Root ſtill too great
Diviſor=4×4³=256)561 Divid.(2.quo    (  —3. 93 leſs, quote.
                          .  .  .     \ 376.07 Root.
                     19987173376 Given number
               38⁴=2085136....
                Diff. 864186624
Diviſ.=4×38³=219|968)864|186 dividend (3.93 quote.
                     660
                     204
                     198
                       6
                       6
                       .
```

Here the aſſumed root being more than juſt, the quotient figure (2) is to be ſubtracted. Alſo I find by involution that 380 is too great, and therefore the next quotient figures are alſo to be ſubtracted.

I venture to take 3 figures the next operation, which being ſubtracted from the former, leaves 376.07 for the root; therefore I doubt not but 376. is either the true root or very near it; and on involving the ſame I find it to be the root required. So by only two ſhort operations, the root of the fourth power is had true to four figures, erring only in the fifth.

N. B. The biquadrate root may be found by firſt extracting the ſquare root, and then the ſquare root of that root; the ſquare cube root, may be found by extracting the ſquare, and then the cube root; the root of the 8th power may be reſolved in 3 ſquare roots; that of the 9th power into two cubes, &c.

Note alſo, Any root of a vulgar fraction is had by extracting the root of both numerator and denominator. But it is better to throw it into a decimal, and then extract it.

A General Method whereby the Roots of all Powers may be readily Approximated.

Rule. Find the neareſt root of the firſt period (whether the ſame be greater than the truth or leſs) and multiply the power thereof by the number denoting the name of the next higher power; alſo multiply the given number by the number denoting the name of the next inferior power, and add theſe two products together. Then as this ſum is to the difference between the given number and the power of the ſaid root (cyphers being annexed to fill up the vacant periods) ſo is twice the root to the correction, which muſt be added to the root if the root was leſs than juſt, but ſubtracted if greater.

N. B. In all odd powers, as the next greater and next leſs are denoted by even numbers, the given number and the power of the root may be multiplied by only half thoſe numbers, or, which is the ſame, the power of the root muſt be multiplied by the greater half of the number denoting the name of the power; and the given number by the leſs half thereof; and then inſtead of twice the root, the root only muſt be taken for the 3d term.

The firſt term of the proportion for the cube root will therefore be twice the cube of the aſſumed root, added to the given number; for the furſolid root, it will be thrice the 5th power of the aſſumed root, more twice the given number; for the root of the 7th power, it will be four times the 7th power of the ſuppoſed root added to thrice the given number, and ſo on.

Example. Let it be required as before, to extract the cube root of 67507.82424. Here 4 is the neareſt root of the firſt period, which, as the root muſt conſiſt of 2 figures of whole numbers, muſt be called 40, and the operation will ſtand thus:

```
The given number       67507.82424 Given numb. 67507.82424
Thrice the neareſt cube 128000     Suppoſed cube 64000.
                 (Sum) 195507.82424   Difference 3507.82424
  As 195507.82424 : 3507.82424 :: 40 : (Correction)
                               40
    1955|07.82&c.)140312.96960(.7177 nearly
                  13685
                    346
                    195
                     151        1ſt Root   40.
                     137        Correction +7177
                      14        Anſwer     40.7177
                      14
```

Note, Here the anſwer at the firſt operation errs only 1 in the ſixth figure, and if the operation be repeated, it will give the Anſwer true to 17 or 18 places. Note alſo, the firſt operation will in any caſe give 3 or 4 true figures, and the next operation will treble the number.

The Inveſtigation of the foregoing Rule.

Let the number denoting the power to be extracted be n, and the given number a; or which is the ſame, let the $\frac{1}{n}^{\text{th}}$ root of a be required. Alſo put $x=$ the true root, and let r be a ſuppoſed root taken near to x (the nearer the better); v, being the exceſs or defect, ſo will $r\pm v=x$. Then $\overline{r\pm v}^{\,n}=a$; and by the binomial theorem $\overline{r\pm v}^{\,n}=r^n\pm nr^{n-1}v+n.\frac{n-1}{2}.r^{n-2}v^2\pm$ &c. which terms for an approximation are ſufficient. Then $\overline{\pm nr^{n-1}+n.\frac{n-1}{2}r^{n-2}v}\times v=a-r^n$, and

$\frac{a-r^n}{\pm nr^{n-1}+n.\frac{n-1}{2}.r^{n-2}v}=v$; but $\frac{a-r^n}{\pm nr^{n-1}}$ is alſo an approximate of v; therefore $v=$

$$\frac{a-r_n}{\pm nr^{n-1}+n.\frac{n-1}{2}r^{n-2}\times\frac{a-r^n}{\pm nr^{n-1}}}=\frac{\pm anr^{n-1}\mp nr^{2n-1}}{+n^2r^{2n-2}+n.\frac{n-1}{2}.r^{n-2}\times\overline{a-r_n}}=$$

$$\frac{\pm ar\mp r^{n+1}}{nr^n+\frac{n-1}{2}\times\overline{a-r^n}}=\frac{\pm ar\mp r^{n+1}}{\frac{n+1}{2}r^n+\frac{n-1}{2}.a}=\frac{\pm 2ar\mp 2r^{n+1}}{\overline{n+1}.r^n+\overline{n-1}.a}$$

$$\frac{\pm a\mp r^n}{\overline{n+1}.r^n+\overline{n-1}.a}\times 2r=\frac{a\backsim r^n}{\overline{n+1}.r^n+\overline{n-1}.a}\times 2r;$$ which resolved into a proportion we have, As $\overline{n+1}.r^n+\overline{n-1}.a : a\backsim r^n :: 2r : v$, the correction to be added to or ſubtracted from r, according as r is taken leſs or greater than x, which proportion in odd powers may be reduced, as has been before ſhewn.

If a Theorem is wanted, that ſhall give x at once, then $r\pm\frac{\pm 2ar\mp 2r^{n+1}}{\overline{n+1}.r^n+\overline{n-1}.a}=x=$ (in either caſe)

$$\frac{\overline{n-1}.r^{n+1}+\overline{n+1}.ar}{\overline{n+1}.r^n+\overline{n-1}.a}=\frac{\overline{n+1}.a+\overline{n-1}\,r^n}{\overline{n+1}\,r^n+\overline{n-1}\,a}\times r,$$ and hence as

$\overline{n+1}\,r^n+\overline{n-1}.a : \overline{n+1}.a+\overline{n-1}\,r^n :: r : x.$

In words thus, aſſume a number, near to the root, whether greater or leſs than the ſame; then to the number denoting the power to be extracted, add 1, and multiply the ſum by the power of the aſſumed root; alſo from the number, denoting the ſaid power, ſubtract 1; and multiply the difference by the given number; and add the two products together, for the firſt term of the proportion.

Likewiſe; multiply the former ſum by the given number, and likewiſe the aforeſaid difference by the power of the aſſumed root, and add theſe two products together, for the ſecond term in the proportion.

Then the 3d term will be the aſſumed root, and the 4th term or anſwer will be a nearer value of the root, containing thrice the number of figures that were true in the root before.

In odd powers, the proportion may be reduced by dividing the firſt and 2d terms by 2; and ſo, in the cube root, the firſt term will be twice the cube of the ſuppoſed root, added to the given number; and the 2d, twice the given number added to the cube of the ſuppoſed root: in extracting the root of the fifth power, the firſt term will be 3 times the 5th power of the ſuppoſed root, added to twice the given number; and the ſecond term, three times the given number, more twice the fifth power of the aſſumed root.

In the root of the 7th power, the firſt term will be 4 times the 7th power of the aſſumed root, more 3 times the given number, and the ſecond term, 4 times the given number added to 3 times the 7th power of the ſuppoſed root, and ſo on.

A rule for the cube root, agreeing with this latter method, has been given by ſome authors; but I know of none who have inveſtigated one general proportion, for approximating the roots of all powers.

Mr. Burrow, late mathematical maſter at the Tower, and author of the Gentleman and Ladies Diaries, &c. to whom I was formerly aſſiſtant, made ſome attempts; but the method that he took, though a gentleman of excellent abilities, was not well adapted to the purpoſe; for after all that he did in this buſineſs, the matter was ſtill left to be gueſſed at; and, in many caſes, it would require fifty times the trouble to aſcertain a fit proportion for extracting the roots of a particular power, that I have been at in inveſtigating and giving two general Proportions for extracting the Roots of all Powers.

The firſt of theſe methods will be found to have the preference in point of expedition; as by the latter method a longer diviſion (by $\frac{1}{2}$ part) muſt be uſed, than is neceſſary in the former.

Another New Method for extracting the Cube Root.

Rule. Find the neareſt root of the firſt period, whether greater or leſs than the truth, and thereto annex cyphers to ſupply the vacancy of the remaining figures to be had in the root. Divide the difference between four times the number to be extracted, and this root (ſo ordered) by thrice the ſaid root. Then the ſquare root of the quotient, added to the aſſumed root, will be equal to twice the required root; or ſuch root may be taken for a new operation, if more accuracy is wanted.

N. B. This method will nearly treble the number of true figures in the root, at each operation.

Example. What is the cube root of 7892485271?

```
                         7892485271|2000 = neareſt root
                                  4|
                        31569941084 = 4 times given number
                         8000000000 = cube of neareſt root
Thrice neareſt root=6000)23569941|084 = difference
                          . . . . .  |
                          3928323.514|1982 = ſquare root
                          1          |2000 = aſſumed root
                 29      |292      2 (3982 = ſum
                  9      |261          1991 = cube root req.
                 388     | 3183
                  .      | 3104
                             79
                             78
                              1
```

ARTICLE XIII.

BARTER.

Definition.

Barter is the exchanging of one commodity for another in trade, ſo as neither party may ſuſtain loſs thereby.

Rule I. Find the value of that commodity, whoſe quantity is given, and find alſo what quantity of the other, at its propoſed rate, will amount to the ſame money: then ſo much of the latter commodity muſt be given for the former.

Rule II. When one commodity is advanced above the ready money price, find the advanced price of the other in the ſame proportion; and then proceed as above.

Example I. How much ſugar at 8d. per lb. muſt be given for 16 ctw. of tobacco at 5 l. per cwt.?

Here 16 cwt. of tobacco at 5 l. per cwt. comes to 80l. then ſay, As 8d. : 80 l. (or 19200 pence) :: 1 : (Anſwer.)

Therefore $\frac{19200}{8}=2400$ lb. of tobacco, or 21 cwt. 1 qr. 20 lb. the Anſwer.

Example II. A and B barter with each other. A hath 200 yards of cloth at 6s. 8d. per yard, ready money, but in barter he will have 8s. per yard. B has hops at 1l. 14s. per cwt. ready money. How many cwt. of hops muſt B give A for his cloth, ſo that his gain in the barter may be equal to A's?

As 6s. 8d. (or 80 pence) : 1l. 14s. (408 pence) :: 8 s. : (price of hops in barter.)

Then $\frac{408\times 8}{80}=40.8$s. the price which B's hops muſt be charged at per cwt. in barter. Alſo A's 200 yards of cloth at 8s. comes to 80 l.

An

And as 40.8s. : 80l. (or 1600s.) : : 1 cwt. : (the Anſwer.)

Therefore $\frac{1600}{40.8} = \frac{200}{5.1} =$ 39 cwt. 0. qr. 24 $\frac{8}{51}$ lb. the Anſwer required.

Quest. III. Two merchants, A and B, barter with each other. A has 460 yards of broad cloth, worth 9s. 2d. per yard, but in barter he will have 11s. per yard. B has coffee at 2s. per lb. for which he charges 2s. 6d. How much coffee muſt A receive for his cloth, and what does he gain or loſe by the bargain?

Here A's cloth, at 11s. per yard, comes to 5060 ſhillings.

And as 2s. 6d. (or 2.5) : 5060 : : 1lb. : to the quantity of coffee, which A muſt receive.

Therefore $\frac{5060}{2.5} = \frac{1012}{.5} =$ 2024 lb. = the pounds of coffee, which B muſt give A for his cloth.

Now, to find the gain or loſs of either party in this tranſaction.

As 9s. 2d. (or 110d.) : 2s. (or 24d.) : : 11s. : the value that B's coffee ought to be charged at per lb. ſo as neither to gain nor loſe, = 2.4s. And therefore, as 2.4s. : 5060s. : : 1lb. : the quantity of coffee which B ought to give A for his cloth, $= \frac{5060}{2.4} = \frac{1265}{.6} = 2108\frac{1}{3}$ lb. But B only gives A 2024 lb. and therefore he ſaves $84\frac{1}{3}$ lb. which at 2s. per lb. the prime coſt of the coffee, comes to 8l. 8s. 8d. the gain of B by this bargain. And ſo much alſo A loſt.

ART. XIV. FELLOWSHIP.

Definitions.

I. Fellowſhip is a general rule by which merchants, tradeſmen, &c. in company determine each perſon's particular ſhare of the gain or loſs in proportion to his ſhare in the joint ſtock.

II. Fellowſhip is either double or ſingle.

III. Single Fellowſhip is when each perſon's ſtock is employed during one and the ſame given time.

IV. Double Fellowſhip is when the different ſtocks are employed for unequal portions of time.

THE RULE FOR SINGLE FELLOWSHIP.

As the whole ſtock is to the whole gain or loſs, ſo is each man's particular ſtock to his particular ſhare of the gain or loſs.

Question I. A and B have gained by trading 160l. A put into ſtock 300l. and B 500l. what is each perſon's ſhare of the gain?

Here the whole ſtock is 800l. And as 800l. : 160l. : : 300l. : to the ſhare of A $= \frac{160 \times 300}{800} = \frac{2 \times 300}{10} = \frac{2 \times 30}{1} =$ 60. Alſo, as 800l. : 160l. : : 500l. : to the ſhare of B $= \frac{160 \times 500}{800} = \frac{2 \times 500}{10} = \frac{2 \times 50}{1} =$ 100l.

Moreover 60l. the gain of A, added to 100l. the gain of B, makes 160l. the whole gain, which ſhews that the work is right.

Schol. I. After the gain or loſs of one perſon is found, the reſt may be found without uſing the whole gain or loſs, and the whole ſtock, by ſaying, as that perſon's ſtock is to his gain, or loſs, ſo is any other perſon's ſtock to his gain, or loſs, and it will frequently happen that, by this method, the different Anſwers will be obtained in a ſhorter way than by adhering ſtrictly to the foregoing Rule, eſpecially if one be mindful to embrace every contraction that may preſent itſelf in the operations, as deſcribed in the Rule of Three.

Schol. II. When it does not appear that the method pointed out in the laſt Scholium will be attended with any advantage; then when there are many joint ſtocks to ſettle, or caſes of bankruptcy, &c. it will be a good way to find the gain or loſs upon 1l. which is done by dividing the whole gain by the whole ſtock. Then multiply the quotient by each man's particular ſtock, and it will give his particular ſhare of the gain or loſs.

This method will ſave a repetition of diviſions; and the multiplications may alſo be ſhortened by beginning with the ſmalleſt ſhare firſt; for then the next may be wrought by multiplying the ſaid quotient by the difference between that and the former ſtock, and adding the product to the former; and the next, by multiplying by the difference between that ſtock and the preceding, and adding the product in like manner to the preceding ſhare, and ſo on; always going forward to the next greater ſtock.

Thus, in the laſt example, the gain of 1l. ſtock $= \frac{160}{800} =$ 2l. And $300 \times .2 = 60$l. = gain of A. Alſo, 200 (or $500 - 300$) $\times .2 = 40$l. and $60 + 40 = 100$l. = gain of B.

Question II. Four perſons in partnerſhip, A, B, C, and D, put into ſtock 360l. 480l. 700l. and 860l. reſpectively, for a certain time, at the end of which they have gained 3960l. what is each perſon's ſhare of the gain?

$$\begin{array}{ll}
\text{£.} & \\
360 = & \text{A's ſtock.} \\
480 = & \text{B's.} \\
700 = & \text{C's.} \\
\underline{860} = & \text{D's.} \\
2400 = & \text{Whole ſtock.}
\end{array}
\qquad
\begin{array}{lrcrcrcrl}
 & & & \text{£.} & & \text{£.} & & \text{£.} & \text{£. Share.} \\
\text{Then, As} & 2400 & : & 3960 & :: & 360 & : & 594 & = \text{A's} \\
\text{As} & 3 & : & 4 & :: & 594 & : & 792 & = \text{B's} \\
\text{As} & 24 & : & 35 & :: & 792 & : & 1155 & = \text{C's} \\
\text{As} & 35 & : & 43 & :: & 1155 & : & \underline{1419} & = \text{D's} \\
 & & & & & \text{Whole gain} & & 3960 & \text{Proof.}
\end{array}$$

Example III. Four men, A, B, C, and D, bought a caſk of ale for 20 ſhillings, and agreed that each man's part of the purchaſe ſhould be as $\frac{1}{3}$, $\frac{1}{4}$, $\frac{1}{5}$, and $\frac{1}{6}$, reſpectively; what muſt each pay?

Here the fractions, reduced to the leaſt common denominator, are $\frac{20}{60}$, $\frac{15}{60}$, $\frac{12}{60}$, and $\frac{10}{60}$; and, conſequently, the ſhares will be as 20, 15, 12, and 10, reſpectively.

Then $20 + 15 + 12 + 10 = 57$.

$$\begin{array}{llcccccl}
 & & & & & \text{s. d. f.} & & \text{s. d. f.} \\
\text{And, As} & 57 & : & 20 & :: & 20\ 0\ 0 & : \text{to the ſhare of A} = & 7\ 0\ 0\frac{48}{57} \\
\text{As} & 4 & : & 3 & :: & 7\ 0\ 0\frac{48}{57}: & \text{ſhare of B} = & 5\ 3\ 0\frac{36}{57} \\
\text{As} & 5 & : & 4 & :: & 5\ 3\ 0\frac{36}{57}: & \text{ſhare of C} = & 4\ 2\ \frac{1}{2}\frac{6}{57} \\
\text{As} & 2 & : & 1 & :: & 7\ 0\ 0\frac{48}{57}: & \text{ſhare of D} = & \underline{3\ 6\ 0\frac{24}{57}} \\
 & & & & & & = & 20\ \text{Proof.}
\end{array}$$

Example IV. Five men trade together, and compoſe a ſtock of 823l. 15s. A put in 96l. 10s. B, 108l. 5s. C, 162l. 6s. D, 196l. 6s. and E, 260l. 8s. and their whole gain is 98l. 17s. What is each man's part thereof?

Here the whole gain, 98.75l. being divided by the whole ſtock, gives .12l. for the gain of 1l. which therefore will be a common multiplier. Then,

$$\begin{array}{l}
\text{l.} \\
96.5 \\
108.25 \\
162.3 \\
196.3 \\
\underline{260.4} \\
823.75
\end{array}
\left.\vphantom{\begin{array}{l}1\\1\\1\\1\\1\end{array}}\right\} \times .12 =
\left\{\begin{array}{lcrrrlcl}
\text{l.} & & \text{l.} & \text{s.} & \text{d.} & & & \\
11.58 & = & 11 & 11 & 7 & .8 & = & \text{A's ſhare.} \\
12.99 & = & 12 & 19 & 9\frac{1}{2} & .4 & = & \text{B's.} \\
19.476 & = & 19 & 9 & 6 & .96 & = & \text{C's} \\
23.556 & = & 23 & 11 & 1\frac{1}{4} & .76 & = & \text{D's} \\
31.248 & = & \underline{31} & \underline{4} & \underline{11\frac{1}{2}} & .08 & = & \text{E's.} \\
 & \text{£} & 98 & 17 & 0 & \text{Proof.} & &
\end{array}\right.$$

Schol. III. If the whole ſtock, and each man's gain or loſs be given to find the particular ſtock of each, then ſay, as the whole gain is to the whole ſtock, ſo is each man's gain to his ſtock.

THE RULE FOR DOUBLE FELLOWSHIP.

Multiply each man's ſtock by the time of its being in trade, and add the ſeveral products into one ſum; then ſay, as that ſum is to the whole gain or loſs, ſo is the product of each man's ſtock and time, to his part of the gain or loſs.

Example I. Three merchants, A, B, and C, enter into partnerſhip: A put in 60l. for 4 months: B, 50l. for 3 months: C, 30l. for 2 months: and the whole of the gain is 60l. What is each man's part thereof?

$$\left.\begin{array}{r}
\text{l.} \\
60 \times 4 = 240 \\
50 \times 3 = 150 \\
30 \times 2 = \underline{\ 60} \\
\text{£}\ 450
\end{array}\right\} \text{Then, as}
\left\{\begin{array}{rcrcrcrcl}
 & & \text{l.} & & & & \text{l.} & & \\
450 & : & 60 & :: & 240 & : & 32 & = & \text{A's ſhare.} \\
450 & : & 60 & :: & 150 & : & 20 & = & \text{B's} \\
450 & : & 60 & :: & 60 & : & \underline{8} & = & \text{C's.} \\
 & & & & & \text{£} & 60 & & \text{Proofs.}
\end{array}\right.$$

Schol. I. When there are many in partnerſhip, it will expedite the work to divide the whole gain or loſs by the ſum of the products of each man's ſtock and time, and multiply the reſpective quotients by each of ſuch products, and the reſults will be the ſeveral anſwers required. And this way alſo may be frequently rendered ſhorter, by beginning with the leaſt product, and proceeding according to the differences as ſtated in Schol. II. of Single Fellowſhip: or, having calculated one man's ſhare, you may ſay, as the product of his ſtock and time is to the product of any other man's ſtock and time, ſo is the gain more or loſs of the former partner to the gain or loſs of the latter.

Schol. II. When the whole ſtock, the time of each man's continuing in partnerſhip, and the gain or loſs of each is given, to find the proper ſtock of each, it may be done thus.

Divide each man's gain by the time, and add the ſeveral quotients into one ſum. Then ſay, as the ſum of the quotients is to the whole ſtock, ſo is each quotient to the correſponding ſtock; or find by Problem IV. of Fractions, the leaſt number that is diviſible by each man's time, and let the ſame be ſeverally divided by each ſuch time accordingly. Alſo multiply each of the reſpective quotients by the correſponding gain or loſs, and add all the products into one ſum, noting diſtinctly to what perſon each relates; then ſay, as the whole gain or loſs is to the ſaid ſum, ſo is each product to the correſpondent ſtock, or to the ſtock of ſuch partner as the product in operation had a reference to.

N. B. This latter method will be preferable, when there is a remainder in dividing any of the gains by its time.

Example II. Three perſons, A, B, and C, hire a piece of land for 6l. 10s. To which ſum A contributed 11l. 5s. B, 20l. and C, 29l. 5s. Now they propoſe to ſtock the ſame with oxen, and that A's oxen ſhall be at paſture for $4\frac{1}{2}$ months; B's, for 5 months; and C's, for $6\frac{1}{2}$ months. The number of oxen to be fed is 22. How many muſt each man put to graſs?

Here the times are 9 half months, 10 half months, and 13 half months, reſpectively; and the leaſt number which is diviſible by each of them $= 9 \times 10 \times 13$. And therefore the multiplier in the caſe of A, is $\frac{9 \times 10 \times 13}{9} = 10 \times 13 = 130$; in that of B is $\frac{9 \times 10 \times 13}{10} = 9 \times 13 = 117$; and in that of C, is $\frac{9 \times 10 \times 13}{13} =$ 90. Then

$$\left.\begin{array}{r}
11.25 \times 130 = 1462.5 \\
20 \times 117 = 2340. \\
29.25 \times \ 90 = \underline{2632.5} \\
6435

ART. XV. ALLIGATION, &c.

Definitions.

I. Alligation teacheth how to mix ſimples of different qualities, ſtrengths, values, or rates, ſo that the compoſition may be of ſome intermediate quality, ſtrength, or value.

II. Alligation is of four kinds, viz. Medial, Alternate, Partial, and Total.

III. Alligation Medial, is the method of finding the rate of the compound, from having the rates and quantities of the ſeveral ſimples given.

IV. Alligation Alternate teaches, by knowing the rate of the compound, and the rates of the ſimples of which it is compoſed, to find the proportional quantities of each ſort, to form ſuch a mixture.

V. Alligation Partial is when the rates of the ſimples, the rate of the compound, and the quantity of one (or more) of the ſimples to be mixed, are given to find the ſeveral quantities of the reſt of the ſimples.

VI. Alligation Total is when the rates of the ſimples, the rate of the compound, and the quantity of the compound are given, to find the reſpective quantities of the ſimples uſed in making that quantity of the compound.

THE RULE FOR ALLIGATION MEDIAL.

Multiply each quantity by its rate; and divide the ſum of the products, by the ſum of the quantities, (or whole compoſition) and the quotient will be the rate of the compound required.

Example. A Vintner would mix together 80 gallons of malaga, at 8s per gallon; 50 gallons of ſherry, as 5s 6d per gallon; 32 gallons of canary, at 7s per gallon; and 29 gallons of white wine, at 4s 6d per gallon: how muſt the mixture be ſold?

Here, 8s. × 80 = 640
5.5 × 50 = 275
7. × 32 = 224
4.5 × 29 = 130.5
191 1269.5

191) 1269.5 (6s
1146
123.5
12
191) 1482. (7
1337
145
4
191) 580 (3
573
7

Anſwer, 6s. $7\frac{3}{4}$d. and $\frac{7}{191}$ of a farthing.

Schol. When in the given quantities there are fractional parts, it will be convenient before you commence the operation, to reduce them all to fractions, having the leaſt common denominator.

Then the denominators, being common, may be rejected, and the operation carried on with the numerators, as though they were given whole numbers.

THE RULE FOR ALLIGATION.

Alternate.

I. Set down the rates of the ſimples in a column under each other; and write down the rate of the compound oppoſite the middle of the column, and on the left thereof.

II. Connect, or link with a crooked or curve line, the rate of each ſimple, which is leſs than that of the compound, with one or any number of thoſe that are greater; and link each greater rate with one, or any number of the leſs.

III. Write down the difference between the rate of the compound, and that of each ſimple, oppoſite the rate to which it is linked.

IV. Then if only one difference is found oppoſite any rate, it will be the quantity belonging to that rate; but, if there be ſeveral, their ſum will be the rate.

N. B. Queſtions of this kind admit of innumerable anſwers, and are of the ſame nature with thoſe under the head *Indeterminate Problems*, in the Syſtem of Algebra.

Therefore to obtain more anſwers than the above rule will give, take, inſtead of the differences belonging to any couple of rates, any multiple thereof, whatever.

Do this with as many couple of rates, as you pleaſe; through which there will be had a new ſet of differential numbers, exhibiting freſh anſwers. And thus by repeating the operation with different multiples, any number of anſwers may be derived; for the variety is infinite, or in general; (though it may ſeem a paradox) infinitely infinite, or an infinity of infinity.

Example. How much ſherry at 2s. 3d. canary at 2s. 9d. and port at 1s. 2d. per quart, muſt be taken to form a compound of the value of 1s. 6d. per quart?

Pence
18d. | 33 | 4 | | 4 = quantity of canary
| 27 | 4 | | 4 = ditto ſherry
| 14 | 9 15 | 24 = ditto port

Hence, to make the mixture, there may be taken 4 quarts of canary, 4 quarts of ſherry, and 24 of port, or any quantities in thoſe proportions; or, if the differences of either, or both the couples be multiplied by any aſſigned number, other proportions will be had that will ſatisfy the enquiry, even (by repetitions) to a number greater than any aſſignable one.

Thus, if the differences 4 and 15, belonging to 33 and 14, be doubled, then the proportions will become 8, 4, and 39, reſpectively; if trebled, they will be 12, 4, 54; and ſo on, the proportions ever varying as a different multiple is applied.

Again, if the differences 4 and 9, belonging to 27 and 14, be doubled, and not the other, then the proportions will be 4, 8, and 33, reſpectively; if trebled, they will be 4, 12 and 42, and ſo on for any other multiple.

Therefore, it is evident, that this Example admits of an infinitely infinite variety of proportions.

THE RULE FOR ALLIGATION.

Partial.

Find the proportions as for Alligation alternate; then ſay, as the difference or proportionate number, belonging to the ſimple or ingredient, whoſe quantity is given, is to the difference or proportionate number, belonging to any other ſimple, &c. ſo is the quantity of the former ſimple, &c. to the quantity of the latter.

And thus the quantities of each ſimple may be found ſo as to form the propoſed compound, when the quantity of one of the ſimples is given.

If the quantities of two or more ſimples are given, and it is required to determine the quantities of ſeveral others ſo as to form a given compound, then by Alligation medial find the quality, rate, or value of a mixture compoſed of the ſimple, whoſe quantities are given, and ſubſtitute the whole of the ſame, inſtead of the ſaid given quantity; and ſo they will be reduced, as it were, to one ingredient, whoſe quantity and rate, or value, &c. is given; and therefore, the unknown quantities will be found by the preceding rule.

Question. What quantity of gold of 15, of 17, and of 22 carats fine, muſt be mixed with 6 oz. of carats fine, ſo that the compoſition may be of 20 carats fine?

20 | 15 | 2 | 2
| 17 | 2 | 2
| 22 | 5,3,2 | 10
| 18 | 2 | 2

Then as 2 : 6 : : 2 : 6 oz. of 15 carats fine
2 : 6 : : 2 : 6 do. of 17 ditto
2 : 6 : : 10 : 30 do. of 22 ditto

Hence, there muſt be 6 oz. of 15 carats fine, 6 oz. of 17 carats fine, and 30 oz. of 22 carats fine.

N. B. If the quantities of two had been given, as for inſtance, if not only the 6 oz. of 18 carats fine had been given, but alſo the 6 oz. of 15 carats fine, then by the firſt rule they are reduced to 12 oz. of $16\frac{1}{2}$ carats fine.

When the queſtion is reduced to this, viz. to find how many ounces of 17 carats fine, and 22 carats fine, muſt be mixed with 12 oz. of $16\frac{1}{2}$ carats fine, ſo that the compoſition may be of 40 carats fine; and the anſwer is 12 oz. of 17 carats fine, and 39 of 22 carats fine; which numbers, though different from the former, do equally anſwer the conditions of the queſtion; for if, inſtead of the differences belonging to the couplet 17 and 22, the double thereof had been taken in the former caſe (which, according to the rule, would have been equally right) then the numbers in the firſt anſwer would have been the ſame as in this; or, if in the latter caſe, the ſame differences had been multiplied by $\frac{1}{2}$, or which is equivalent, if the half thereof had been taken, inſtead of working with the whole, then the numbers in this anſwer would have been the ſame as in the former.

But note, if after the ſeveral ingredients are reduced to one as above, that the rate or value thereof, together with the ſeveral rates or values of the reſt of the compounds, be all either above or below the propoſed rate or value of the whole compound, then the caſe is impoſſible.

This method of proceeding, when the quantities of two or more ſimples are given, I have not ſeen exemplified elſewhere.

THE RULE FOR ALLIGATION TOTAL.

When the ſum of all the quantities to be mixed is given, add up all the differences, or proportionate numbers together; then ſay, by the Rule of Three, as that ſum is to the whole given quantity, ſo is each particular difference or proportionate number to its reſpective quantity.

Question. A goldſmith has gold of different ſorts, viz. of 24, 23, 22, and 21 carats fine, reſpectively, as alſo a quantity of alloy, from which he wants to make a maſs of 200 oz. that ſhall be 20 carats fine; how much of each ſort muſt he take?

20 | 24 | 20 | 20
| 23 | 20 | 20
| 22 | 20 | 20
| 21 | 20 | 20
| 0 | 4,3,2,1 | 10
| | | 90

Then, as 90 : 200 : : 20 : $44\frac{4}{9}$ oz. which is the quantity that the goldſmith muſt take of 24, 23, 22, and 21 carats fine reſpectively.

Alſo as 90 : 200 : : 10 : $22\frac{2}{9}$ oz. the quantity of alloy.

N. B. Alloy is reckoned at 0 carats fine.

Schol. If not only the whole quantity, but alſo the quantity of ſome particular ingredient is given; then find the rate, quality, or value of the compound, as though that particular ingredient was not included; which is done thus,

Multiply the quantity of the whole compound by its propoſed quality, rate, or value, &c. Alſo multiply the given quantity by its rate or value, &c. and ſubtract the latter product from the former. Then divide the remainder by the difference between the whole weight and the given weight, and the quotient will be the value, rate, &c. of the compound, provided the quantity and quality of the given ingredient were deducted therefrom. Therefore

fore make the quantity of the compound equal to the difference between the whole quantity and the given quantity, and its quality or rate, &c. equal to the Anſwer brought out as above, and proceed with the remaining ingredients to find their reſpective quantities, according to the foregoing Rule.

Thus, in the laſt Example, if the quantity of 24 carats fine had been given $= 44\frac{4}{9}$ oz. and it had been required to determine the quantities of the reſt; then $200\times20 = 4000$, and $24\times44\frac{4}{9} = 1066\frac{2}{3}$; and $4000 - 1066\frac{2}{3} = 2933\frac{1}{3}$. Alſo $200 - 44\frac{4}{9} = 155\frac{5}{9}$; and $2933\frac{1}{3} \div 155\frac{5}{9} = 18\frac{6}{7}$ carats; the fineneſs of the maſs, provided the $44\frac{4}{9}$ oz. of 24 carats were not included.

Therefore the queſtion is now reduced to this, viz. to find what quantities of 23, 22, and 21, carats fine, and of alloy muſt be mixed together to form a maſs of $155\frac{5}{9}$ oz. weight that ſhall be of the fineneſs of $18\frac{6}{7}$ carats; and the operation will ſtand as under;

$$18\tfrac{6}{7}\left|\begin{array}{l}23\\22\\21\\0\end{array}\right.\;\begin{array}{l}18\frac{6}{7}\\18\frac{6}{7}\\18\frac{6}{7}\\4\frac{1}{7},3\frac{1}{7},2\frac{1}{7}\end{array}\;\left|\begin{array}{r}18\frac{6}{7}\\18\frac{6}{7}\\18\frac{6}{7}\\ \underline{9\frac{2}{7}}\\66\end{array}\right.$$

Then as $66 : 155\frac{5}{9} :: 18\frac{6}{7} : 44\frac{4}{9}$, the quantity of 23,22 and 21 carats fine reſpectively.

And as $66 : 155\frac{5}{9} :: 9\frac{2}{7} : 22\frac{2}{9}$ the quantity of alloy; the ſame as before.

And thus may any other ſimilar caſe be ſolved; alſo if the whole quantity, and likewiſe the quantity of two or more of the ingredients be given, the anſwer will be obtained in the ſame manner, only the ſeveral ingredients that are given, muſt firſt of all be reduced to one ingredient, as directed in the rule for Alligation partial.

N. B. This caſe I have not ſeen handled in Allegation by any author before.

ART. XVI. EXCHANGE.

Definitions.

I. Exchange is the bartering of money, and conſiſts in finding what quantity of money of one place is equal to a ſpecified ſum of another, according to a given courſe of exchange.

II. The Courſe of Exchange is ſuch a variable ſum of the money of one place, as is propoſed to be given for a certain conſtant ſum of that of another.

III. The Par of Exchange is the intrinſic equality between two pieces or ſums of money, one of which is the conſtant piece or ſum to which the courſe is compared.

IV. The Ageo is the difference of the value of current money and bank money; for the bank money in Foreign countries is finer than the current money.

The operations are all managed by the Rule of Three, Practice, &c.

THE EXCHANGE, WITH IRELAND, AMERICA, AND THE WEST-INDIES.

In thoſe places the accounts are kept in pounds, ſhillings and pence, as in England. The courſe of exchange with Ireland, is from 5 to 12 per cent. in favour of England; according to the ballance of trade; and the par is reckoned at 108l. 6s. 8d. Iriſh, per 100l. ſterling.

In the Weſt Indies, 5l. ſterling is accounted worth 7l. currency.

Example I. Dublin remits to London 690l. Iriſh, how much ſterling muſt Ireland be credited, the courſe of exchange being 8 per cent?

Here, As 108l. : 690l. :: 100l. : $\frac{690\times100}{108} = \frac{69000}{2\times54} = \frac{34500}{54} = \frac{34500}{6\times9} = \frac{5750}{9} =$ 638l. 17s. $9\frac{1}{4}$d. and $\frac{1}{3}$ of a farthing, the Anſwer.

Example II. London remits to Ireland 787l. 15s. ſterling, how much Iriſh muſt London be credited, exchange at $10\frac{1}{2}$ per cent?

Here, As 100l. : 787l. 75 :: 110l. 5 : $\frac{110.5\times787.75}{100} =$ 870.46375l. = 870l. 9s. $3\frac{1}{4}$d. and $\frac{2}{10}$ of a farthing, the Anſwer.

N. B. Through an *odd miſtake*, Mr. Bonnycaſtle, in his Arithmetic has brought out the anſwer to this queſtion, 791l. 13s. $3\frac{1}{4}$d. and $\frac{2}{10}$ parts, which is 78l. 16s. too little.

Example III. Virginia is indebted to London 550l. ſterling: how much currency will London be credited at Virginia, when the exchange is $33\frac{1}{3}$ per cent?

Here, As 100l. : 550 :: $133\frac{1}{3}$: $\frac{550\times133\frac{1}{3}}{100} = 733.33\frac{1}{3}$l. = 733l. 6s. 8d. the Anſwer.

THE EXCHANGE WITH HOLLAND, FLANDERS, AND GERMANY.

Accounts in theſe places are ſometimes kept in pounds, ſhillings and pence, but frequently in gilders, ſtivers and pennings.

The money of Holland and Flanders is called Flemiſh, and they exchange by the pound ſterling. The exchange is from 33s 6d. to 36s. Flemiſh per pound ſterling. The agio is from 3 to 6 per cent for current.

Note. Eight pennings make 1 grote or penny; 2 grotes, 1 ſtiver; 6 ſtivers, 1 ſchilling; 20 ſtivers, 1 florin or guilder; $2\frac{1}{2}$ florins, 1 rix dollar; and 6 florins, 1 pound Flemiſh.

To turn current Money in Banco.

Rule. Add the agio to 100, then ſay as that ſum is to any given ſum current, ſo is 100 to the value of the ſaid ſum current in banco.

To turn Banco Money in Current.

Rule. As 100 is to any given ſum banco, ſo is 100 with the ageo, added to it, to its value current.

N. B. The exchange is ſuppoſed to be in bank money, and therefore current money muſt be always reduced to banco, before the exchange is made.

To change Sterling Money into Flemiſh.

Rule. As 1l. ſterling, is to the ſum ſterling given, ſo is the given rate to the Flemiſh ſought.

To change Flemiſh Money into Sterling.

As the given rate is to the given ſum Flemiſh, ſo is 1l. ſterling to the ſterling required.

N. B. Theſe caſes may frequently be commodiouſly wrought by the rules of practice.

Example. Suppoſe there be due at Rotterdam 63:6 guilders, 1 ſtiver and 15 pennings current money, and the ageo be $4\frac{7}{8}$ per cent: how much ſterling money does it come to, the exchange being at 33s. $5\frac{1}{2}$d. Flemiſh per pound ſterling?

Firſt reduce the current money into banco, thus. As $104\frac{7}{8}$ cur. : 631 guild. 1 ſtiv. 15 pen. cur. :: 100 bank : 6022 guild. 10 ſtive. banco.

Now reduce the banco into Flemiſh, thus: 6022 guild. : 10 ſtiv. Flemiſh is equal to 1003l. 15s. Flemiſh, which is found by dividing by 6, becauſe 6 florins or guilders is 1l. Flemiſh. Then as 33s. : $5\frac{1}{2}$d. :: 1003l. 15s. :: 1l. : 600l. ſterling, the Anſwer; and the like for other queſtions of this nature.

THE EXCHANGE WITH FRANCE.

The French accounts are kept in livres, ſols, and deniers, exchange being made by the French crown, the par of which is 4s. 6d. ſterling.

Note I. Twelve deniers make 1 ſol or ſou; 20 ſols, 1 livre, and 3 livres, 1 crown or ecu. Alſo 10 livres make a piſtole, and 24 livres, 1 louis d'or, or guinea.

Note II. The livres are imaginary money, but the crowns, ſols, and deniers are real.

Note III. The term tournois is only a note of diſtinction of the French money, as ſterling is of the Engliſh.

Note IV. In the French exchange, you muſt diſtinguiſh between exchange money and book money. The exchange money is called money d'or, and is expreſſed in crowns, ſols, and deniers d'or. The book money is called tournois, and is expreſſed in livres, ſols, and deniers tournois. Alſo crowns, ſols, and deniers d'or, being multiplied by 3, throughout, give livres, ſols, and deniers tournois, or book money; and, on the contrary, book money, being divided by 3, gives the exchange money.

Note V. The exchange is from 30d. to 32d. per crown or ecu.

Example. How many livres, &c. tournois, will 360 l. ſterling amount to, the exchange being at 30d. per crown, or ecu?

Here, as 30d. : 360l. (or 86400 pence) :: 1 ecu : $\frac{84400}{30} =$ 2880 crowns, or ecu's, which, multiplied by 3, gives 8640 livres tournois.

THE EXCHANGE WITH SPAIN.

In Spain they keep their accounts in piaſtres, rials, and maravedies, reckoning 34 maravedies to a rial, and 8 rials to a piaſtre, *peſo*, or piece of eight, old money, by which they exchange, the par being 4s. 6d. The piaſtre is imaginary, but the rials and maravedies are real. Alſo London exchanges with Spain in pieces of eight, new money, of 10 rials.

Note, likewiſe, 5 piaſtres is a Spaniſh piſtole, and 2 piſtoles is a doubloon.

Example. How many piaſtres ſhall I receive in Spain for 510 l. ſterling, the exchange being at 50d. per piaſtre?

Here, as 50d. : 510 l. (or 122400 pence) :: 1 piaſtre : $\frac{122400}{50} = \frac{244800}{100} = 2448$, the Anſwer.

N. B. In Genoa, and Leghorn, they keep their accounts in ſols and deniers, as in France, but exchange by the piaſtre, as in Spain. At Venice alſo, accounts are by ſome kept in the ſame manner, and by others, in ducats and groſs, reckoning 24 groſs to a ducat.

Examples of exchange with other countries might be given, but as they are all founded on the ſame principles of computation, it would be ſuperfluous to enumerate them.

ART. XVII. INTEREST.

Definitions.

I. Intereſt is the premium or reward allowed for the loan or uſe of any ſum of money for any appointed time.

II. The Principal is the money lent or put out to intereſt.

III. The Rate of Intereſt is the Intereſt of 100l. for a year, but frequently the Intereſt of 1 l. for a year is termed the Rate of Intereſt.

IV. The Amount of a ſum of money at the expiration of a given time, conſiſts of the Principal, together with its Intereſt for that time.

V. Alſo, Intereſt is either Simple or Compound.

VI. Simple Intereſt is that which is charged only upon the principal from the time of its being put out to Intereſt, or of its becoming due, if an arrear.

VII. Compound Intereſt, or Intereſt upon Intereſt, is that which is continually derived from both Principal and Intereſt, ſo that the Intereſt itſelf, as it ariſeth, is ſuppoſed to be perpetually gaining Intereſt, as well as the Principal.

I ſhall treat of them both diſtinctly; and firſt,

OF SIMPLE INTEREST.

All the queſtions of Simple Intereſt are reſolved by the Rule of Three; but, as under that Rule I have given no Examples of Intereſt, judging it more methodical to handle the ſubject by itſelf, I ſhall add a few by way of precedent and exerciſe.

Example I. What is the Intereſt of 550 l. for a year, at 5 l. per cent.

As 100 l. : 550 l. :: 5 l. : (Anſwer.)

Then $\frac{550\times5}{100}=5.5\times5=27.5\text{ l.}=27\text{ l. }10\text{s.}$ the Anſwer.

N. B. In caſes like this, where the Intereſt is at 5 per cent. may be had by dividing the given ſum by 20; for 5 is a conſtant multiplier, and 100 is a conſtant diviſor, and $\frac{5}{100}$ is $=\frac{1}{20}$.

In the above Example, the 20th part of 550 l. is 27 l. 10 s. as before.

Example II. What is the Intereſt of 575 l. 12 s. 6 d. for 3 years, at 5 per cent. per annum, Simple Intereſt?

This is done by the Double Rule of Three, as follows:

As 100 l. : 575 l. 12 s. 6 d. :: 5 l. : (1ſt Anſwer.)

As 1 year : 3 years :: 1ſt Anſwer : (Anſwer required.)

Then $\frac{575\text{ l. }12\text{ s. }6\text{ d.}\times5\times3}{1\times100}=\frac{575\text{ l. }12\text{ s. }6\text{ d.}\times3}{20}=\frac{1726\text{ l. }17\text{ s. }6\text{ d.}}{20}=86\text{ l. }6\text{ s. }10\tfrac{1}{2}\text{d.}$ the Anſwer required.

Here, when the Intereſt is at 5 per cent and the time is any number of complete years, the Anſwer is had by multiplying the principal by the time, and dividing the product by 20.

Example III. What is the Intereſt of 894 l. 10 s. 9 d. for 120 days, at 4 per cent. per annum, Simple Intereſt?

By the Double Rule of Three, as below.

As 100 l. : 894 l. 10 s. 9 d. :: 4 l. : (1ſt Anſwer.)

And, As 365 days : 120 days :: 1ſt Anſwer : (Anſwer required.)

Then $\frac{894\text{ l. }10\text{ s. }9\text{ d.}\times4\times120}{100\times365}=\frac{3578\text{ l. }3\text{ s.}\times12}{10\times365}=\frac{42937\text{ l. }16\text{ s.}}{10\times365}=\frac{4293\text{ l. }15\text{ s. }7\frac{1}{5}\text{d.}}{365}=$ (by dividing by 5) $=\frac{858\text{ l. }15\text{ s. }1\frac{11}{25}}{73}$ = (by diviſion as below) 11 l. 15 s. 3¼d. the Anſwer.

Or ſhorter, thus.

$$\begin{array}{r|rrr}
 & \pounds. & \text{s.} & \text{d.}\\
\frac{1}{10} & 858 & 15 & 1\frac{1}{2}\\
\frac{1}{10} & 85 & 17 & 6\\
\frac{1}{3} & 8 & 11 & 9\\
\frac{1}{10} & 2 & 17 & 3\\
\frac{1}{10} & 0 & 5 & 8\frac{1}{4}\ \text{nearly}\\
 & 0 & 0 & 6\frac{1}{4}\\
\hline
 & \pounds\ 11 & 15 & 3\frac{1}{2}\\
 & \text{Subtract} & & \frac{1}{4}\\
\hline
 & \pounds\ 11 & 15 & 3\frac{1}{4}\ \text{Anſwer.}
\end{array}$$

Or, Decimally, thus,

$$\begin{array}{r}
858.75\\
\hline
\frac{1}{3})\ 8.5875\\
2.8625\\
.2862\\
286\\
\hline
11.7648\\
\text{leſs}\quad 11\\
\hline
\pounds\ 11.7637\ \text{Anſwer.}\\
=\pounds\ 11\ \ 15\ \ 3\frac{1}{4}
\end{array}$$

£. Operation.

$$\begin{array}{l}
73\ )\ 858\ \ 15\ \ 1\tfrac{1}{2}\ \text{nearly.}\ (11\\
\quad\ \ \underline{73}\\
\quad\ \ 128\\
\quad\ \ \underline{73}\\
\quad\ \ 55\\
\quad\ \ \underline{\ 20}\\
73\ )\ 1115\ (15\\
\quad\ \ \underline{73}\\
\quad\ \ 385\\
\quad\ \ \underline{365}\\
\quad\ \ \ 20\\
\quad\ \ \underline{\ 12}\\
73\ )\ 241\ (3\\
\quad\ \ \underline{219}\\
\quad\ \ \ 22\\
\quad\ \ \underline{\ \ 4}\\
73\ )\ 90\ (1\\
\quad\ \ \underline{73}\\
\quad\ \ 17
\end{array}$$

Anſwer 11 l. 15 s. 3¼d.

The ſhort method of dividing by 73, is thus;

Divide the given ſum by 100 (or which is the ſame by 10 and 10).

Then take the $\frac{1}{3}$ part of the quotient, and the $\frac{1}{10}$ part of that part, and alſo the $\frac{1}{10}$ part of this latter part. Add the four quotients together, and the ſum will be the Anſwer nearly.

And to correct the ſame for every 500l. in the Anſwer thus obtained, ſubtract 1 ſhilling, and ſo on in proportion for any greater or leſs ſum, viz. for 250l. ſubtract 6d. for 125l. abate 3d. and for each of the intermediate ten pounds, as well as for thoſe below, deduct a farthing; obſerving, to take the neareſt number of tens, whether the ſame ſhall exceed, or fall ſhort of the ſaid ſum.

This method if decimals are uſed as in the 2d ſhort method, is exceeding eaſy; and the decimal to be annexed to the pounds, will be had by dividing the number of ſhillings by 20 (which is no greater difficulty than to take the half thereof) rejecting the pence; but calling the number of ſhillings, one more when the pence exceed ſixpence; as the error in ſo doing can never amount to the $\frac{1}{3}$ part of a farthing, which may always be corrected, ſo, as it can never at all affect the farthings in the valuation, by adding 1 to the figure in the fourth place of the decimal, before it is valued, for every two pence that was left out of the calculation by ſuch method of proceeding; or by ſubtracting therefrom 1, for every two pence that was thereby included above what ought to have been.

In the decimal method, the correction to be ſubtracted from the ſum of the quotients muſt be $\frac{1}{10000}$ part thereof; and the value of the decimal part in the Anſwer is had by inſpection, as I have ſhewn in the Reduction of Decimals.

Cor. From the foregoing proceſs by the Double Rule of Three, it appears, that the ſimple intereſt of any ſum of money, for any number of days at a given rate of intereſt, is found by multiplying the principal, the rate of intereſt, and the number of days together, and dividing the product by 36500.

And to divide by 36500, obſerve theſe rules:

I. Write down the given number, and under it its tenth part; alſo take the $\frac{1}{100}$ part of this part, and write below it; or which is the ſame, multiply it by 4, and ſet the product two figures forward to the right hand; then from the ſum of the two firſt numbers ſubtract the latter (which is eaſy to do in the courſe of adding up, when it is once familiarized) and divide the quotient by 40000, and it will give the Anſwer nearly; which muſt be corrected by deducting from it the $\frac{1}{10000}$ part, as before.

In working by this rule, when you come to divide, both the ſhillings and pence may be neglected; only, if the ſhillings are above 10, it will be as well to make the pounds 1 more; but that is not requiſite, as the error, without that, can never amount to the $\frac{1}{38}$ part of a farthing. Thus the operation is rendered exceeding eaſy.

II. Or the fifth part of the number to be divided, may be taken and that divided by 7300, which will be done by the ſame method that I have given for dividing by 73, only at ſetting out, two more places muſt be pointed off as decimals; viz. the firſt diviſor muſt be 10000 inſtead of 100. This, as well as the preceding method, will want no other correction than the ſubtracting of the $\frac{1}{10000}$ part.

III. Or thus, Write down the number to be divided by 36500; and underneath it write the $\frac{6}{1000}$ part thereof; or which is the ſame, ſet the product by 6, three places forward to the right hand. Alſo multiply this part by 12, placing the product one figure backward, to the left hand: then the ſum of the two under numbers, ſubtracted from the upper number, and the remainder divided by 1000, will give the Anſwer to be corrected as before.

I could give other methods of finding the firſt approximate Anſwer, but none ſeem better adapted to practice than theſe: which methods are ſolely my own, and have never been publiſhed before.

Example V. What is the intereſt of 1422l. 10s. 6d. for 25 days, at 3½ per cent. per annum?

$$\begin{array}{rrr}
\text{l.} & \text{s.} & \text{d.}\\
1422 & 10 & 6\\
 & & 3\frac{1}{2}\\
\hline
4267 & 11 & 6\\
711 & 5 & 3\\
\hline
4978 & 16 & 9\\
 & & 5\\
\hline
24894 & 3 & 9\\
 & & 5\\
\hline
\pounds\ 124470 & 18 & 9
\end{array}$$

1ſt Method of Dividing.

$$\begin{array}{r}

\end{array}$$

Or £ 3. 8s. 2½

2d Method of Dividing.

$$\begin{array}{r}
\pounds.\quad\\
5)\ 124471.\\
\hline
3)\ 2.4894\\
8298\\
830\\
83\\
\hline
3.4105\\
-3\\
\hline
\pounds\ 3.4102\ \text{Anſwer.}
\end{array}$$

3d Method of Dividing.

$$\begin{array}{r}
124471.\\
-746.826\\
-8962\\
\hline
3.4105\\
3\\
\hline
\pounds.\ 3.4102\ \text{Anſwer}
\end{array}$$

Schol. I. The dividing by 3650 or 365 is the ſame as the above, only in the quotient there will be one or two more places of whole numbers reſpectively, and it will be requiſite to annex to the pounds the decimal parts anſwering to the ſhillings, and in the latter caſe when the pence are above ſix-pence it will be as well to call the ſhillings one more, and then no error can ariſe.

Schol. II. Hence when the number of days is diviſible by 10 or 100, the principal may be multiplied by $\frac{1}{10}$ or $\frac{1}{100}$ part thereof inſtead of the whole, and the diviſion made as by 365, or 3650, accordingly.

Schol. III. When the rate of Intereſt is 5 per cent. the principal need only to be multiplied by the time, and the product divided by 7300; in which caſe the ſhillings, &c. may be rejected, or the pounds increaſed 1 more when the ſhillings exceed 10, as was ſhewn in the method for dividing by 36500.

Schol. IV. When the rate of Intereſt is 5 per cent. and the number of days is diviſible by 10 or 100, then the principal need only to be multiplied by $\frac{1}{10}$ or $\frac{1}{100}$ part of the days, and the product divided by 73, or 730; obſerving to retain the decimal of the ſhillings; and in the former caſe, regard being had to the pence, when above ſixpence, as was before ſhewn.

In dividing by 730, one figure more muſt be pointed off to the decimals, than is directed to be done in the dividing by 73.

Schol. V. When the given time conſiſts of years and days, the intereſt may be calculated firſt for the years, and then for the days, and the ſum of both will be the Anſwer; or, when the odd time is given in common months or weeks, without days, it may in ſome caſes be ſufficient to take aliquot parts of the intereſt for a year, for ſuch odd time.

Thus, for 6 months, to take ½, for 4 months, ⅓; for 3 months, ¼; for 2 months, $\frac{1}{6}$; and for 1 month, $\frac{1}{12}$. Alſo for 2 weeks, to take the ½; and for 1 week, the ¼ of the intereſt for 1 month, &c.

This way, however, is a looſe method of calculating, and ſhould never be adopted where ſtrict accuracy is required.

Schol. VI. If the amount, at Simple Intereſt, of any ſum of money for any propoſed time, at a given rate, per cent. is required, the intereſt muſt be found by the foregoing rules, and added to the principal.

Example V. If the Simple Intereſt of 575l. 12s. 6d. for a certain time, at 5 per cent. be 86l. 6s. 10½d. it is required to determine how long the ſame was out at intereſt?

l. pence. l. s. d. pence. year.
As 100 (or 24000) : 575 12 6 (or 138150) :: 1 : (1ſt Anſwer.)
l. farthings. l. s. d. farthings.
And as 5 (or 4800) : 86 6 10½ (or 82890) :: 1ſt Anſ. : (An. req.)

Then $\frac{24000 \times 1 \times 82890}{138150 \times 4800} = \frac{5 \times 8289}{13815} = \frac{8289}{2763} = 3$ years, the Anſwer.

Cor. I. Hence, when the principal, intereſt, and rate of intereſt, are given to find the time at Simple Intereſt.

The rule is, multiply the given intereſt by 100l. for a dividend; and the rate per cent. and the principal together for a diviſor; and the quotient will give the Anſwer in years, or years and parts, or parts of a year; and to know the number of days, if the time be not years complete, multiply the dividend, if the time be under a year; or, the remainder, if it be above a year, by 365; then divide by the ſaid diviſor, and the quotient will be the odd days.

But note, before the above rule is applied, the 100l. and the given principal muſt be reduced to one and the ſame denomination; likewiſe the rate per cent. and the given intereſt muſt alſo be reduced to the loweſt denomination mentioned in the intereſt; or, the odd money of the given principal and intereſt, if any, may be reduced to the decimal part of a pound, and annexed to the pounds, and then no other reduction will be neceſſary; only in multiplying and dividing; the rules for managing decimals, muſt be ſtrictly obſerved.

Cor. II. If the intereſt, the rate of intereſt, and the amount, be given to find the time, ſubtract the intereſt from the amount, and it will leave the principal, with which, and the reſt of the data, proceed as before.

Cor. III. If the rate of intereſt, the principal, and amount, be given to find the time, ſubtract the principal from the amount, and it will leave the intereſt; and ſo the time will be found according to the aforeſaid rule.

N. B. Other rules might have been given for theſe caſes, but none more eaſy than the above; and therefore it would be both needleſs and ſuperfluous to enlarge further on the matter.

Cor. IV. If inſtead of the rate of intereſt, the time be given, and the rate of intereſt be required, then multiply the principal by the time for a diviſor; the dividend will be as before; and quotient will be the rate of intereſt. But note,

1ſt. If the time be days, they muſt either be reduced to the decimal parts of a year, or otherwiſe the dividend, beforementioned, muſt be multiplied by 365, for a proper dividend in this caſe.

2d. If the time be years and days, then the decimal for the odd days may be taken, and annexed to the years; or the whole may be reduced into days, and the proceſs conducted according to the laſt note.

3d. The Anſwer will be of the ſame denomination into which the given intereſt was reduced; which muſt always, as was obſerved, be brought into the loweſt, if decimals are not uſed.

Cor. V. If the rate of intereſt, the time, and the intereſt be given to find the principal, then the rate muſt be multiplied by the time for a diviſor; the dividend being as before, viz. = the intereſt multiplied by 100l. and the Anſwer will be had in pounds, or pounds and parts of a pound.

N. B. All theſe caſes follow eaſy enough from the Rule of Three.

COMPOUND INTEREST.

Problem I. The principal, time, and rate of intereſt, being given, to find the amount or intereſt.

Rule. To 1l. add the decimal, anſwering to the intereſt of 1l. for a year, which, at 3 per cent. is .03, at 3½, is .035; at 4, is .04; at 4½. is .045; at 5, is .05. &c. and this is the amount of 1l. for a year. Then involve this amount to the power denoted by the time, viz. to the ſecond power, if it is 2 years; to the third power, if the time is 3 years; to the fourth, if 4 years, &c. and it will give the amount of 1l. for ſuch time; and this multiplied by the principal (taken decimally if there be odd money) will give the amount of the principal in pounds and decimal parts, from which ſubtract the principal, and it will leave the intereſt.

Example. What is the amount of 550l. for 4 years, at 5 per cent. Compound Intereſt?

Here 1.05 is the amount of 1l. for a year, which involved to the fourth power, is 1.21550625; which multiplied by the principal, 550l. gives 668.5284375l. = 668l. 10s. 6¼d. the Anſwer.

From this ſubtract 550l. and the remainder is 118l. 10s. 6¼d, the intereſt.

Schol. When the time runs high, or is not given in complete years, logarithms ſhould be uſed, or the trouble in ſome caſes would be almoſt immenſe.

But by logarithms, any caſe of this ſort is ſolved with the utmoſt diſpatch. The rule is this, take the logarithm of 1l. and multiply it by the time, taken in years; or, if there be odd days, the days muſt be taken in fractional or decimal parts of a year; and to the product, add the logarithm of the principal in pounds, or pounds and fractional or decimal parts of a pound, if there be odd ſhillings, and the ſum will be the logarithm of the amount; then look in the table of Logarithms for the correſponding number, and it will be the amount itſelf in pounds and decimal parts.

Example. What is the intereſt of 350l. 10s. for 5¼ years, at 3½ per cent. per annum, Compound Intereſt?

Here the amount of 1l. for a year, is 1.035l. and the logarithm thereof, is .0149403; which, multiplied by 5¼ = .0784366. Alſo 350l. 10s. = 350.5l. the logarithm of which is 2.544688, and this added to .0784366 = 2.6231246 = the logarithm of the amount; and conſequently the amount itſelf, is 419.8896l. From this, ſubtract 350.5, the principal, and the remainder is 69.3896l. = 69l. 7s. 9½d. the intereſt required.

Problem II. The intereſt, rate of intereſt, and the principal, or amount, being given to find the time, at Compound Intereſt.

Rule. From the logarithm of the amount, ſubtract the logarithm of the principal, and divide the remainder by the logarithm of the amount of 1l. for a year, and the quotient will be the time required.

Example. If the Intereſt of 350l. 10s. at 3½ per cent. per annum, Compound Intereſt, be 69l. 7s. 9½d. it is required to determine how long the ſame was out at Intereſt?

Here, the Intereſt 69l. 7s. 9½d. = 69.3896l. and the principal 350l. 10s. = 350.5l. conſequently the amount is 419.8896l. The logarithm thereof is 2.6231246. Alſo the logarithm of the principal (350.5l.) = 2.544688; which, ſubtracted from 2.6231246, leaves .0784366, and this divided by .0149403, (the logarithm of the amount of 1l. for a year) = 5.25 years, or 5¼ years, the Anſwer.

Problem III. Given the intereſt, the time, and the amount, or principal, to find the Rate of Intereſt.

Rule. From the logarithm of the amount, ſubtract the logarithm of the principal, and divide the remainder by the time, ſo will the quotient be the logarithm of the amount of 1l. for a year. Then the number anſwering thereto, will be the amount itſelf; from which ſubtract 1l. multiply the remainder by 100; and the product will be the Rate of Intereſt required.

Example. The Compound Intereſt of 350l. 10s. for 5¼ years, being 69l. 7s. 9½d. it is required to determine at what rate, per annum, the ſaid ſum was put out to Intereſt?

Here, as in the laſt Example, the amount is 419.8896l. and the logarithm thereof is 2.6231246. Alſo the logarithm of the principal (350.5l.) is 2.544688; and this ſubtracted from the former, leaves .0784366; which, being divided by 5.25, gives .0149403, the logarithm of 1.035l. and therefore .035l. is the intereſt of 1l. for a year; and 3.5 (or 3½ per cent.) is the rate of intereſt required.

Schol. To facilitate the computations of Compound Intereſt, it has been common to give tables of the amount of 1l. at the different Rates of Intereſt, calculated for as many years as it is probable will occur in practiſe.

Theſe, however, appear unneceſſary here, as in the Syſtem of Annuities, Chap. I. I have given ſuch tables as will always anſwer the ſame purpoſe, with their uſe at large; to which I refer the reader for further information.

DISCOUNT.

Diſcount is but a particular caſe of intereſt, being confined to the ſolution of this Problem, viz. Given the amount, the time, and Rate of Intereſt, to find the intereſt.

In which caſe, the Intereſt is termed the Diſcount; becauſe, it is that money which ought to be diſcounted, or allowed, for the payment of a ſum (equivalent to the amount) at ſo long a time before it becomes due, as is denoted by the given time.

Alſo the principal, in this caſe, is termed the preſent value; becauſe, it is that money which a creditor ſhould receive in preſent payment, in lieu of a ſum equivalent to the amount, and due not till ſuch a period hence, as is expreſſed by the given time.

In Simple Intereſt this, like the reſt of the caſes, is performed by the Rule of Three.

Example. What is the Diſcount of 573l. 15s. due 3 years hence, at $4\frac{1}{2}$ per cent. Simple Intereſt?

By Decimals, thus:

Year Years Int. of 100l. for a year.

As 1 : 3 :: 4.5l. : the Intereſt of 100l. for 3 years, $= 4.5 \times 3 = 13.5$ l.

The Amt. of 100l. for 3 years. The given Amount. Dif. of 1135l. for 3 years.

Then, as $100 + 13.5$ (or 113.5l.) : 573.75l. :: 13.5 : the Diſcount of 573.75l. for 3 years $= \frac{573.75 \times 13.5}{113.5} = \frac{573.75 \times 2.7}{22.7} = \frac{1549.125}{22.7} = 68.2434$ l. nearly $= 68$ l. 4s. $10\frac{1}{2}$d. the Anſwer.

Hence this rule, find the amount of 100l. for the given time, according to the proper Rate of Intereſt. And then ſay, as the amount of 100l. is to the ſum to be diſcounted; ſo is the intereſt of 100l. for the ſaid time, to the Diſcount required; and the Diſcount ſubtracted from the given ſum, leaves the preſent value, or the money, which the ſaid given ſum is worth, in ready caſh.

Schol. When Compound Intereſt is uſed, find, according to the propoſed Rate of Intereſt, the amount of 1l. by the method of Compound Intereſt for the given time. Then divide the given ſum by that amount, and it will give the preſent value; which, ſubtracted from the ſaid ſum, leaves the Diſcount.

In the foregoing Example, the amount of 1l. for 3 years, $= 1.141166125$; and $\frac{573.75}{1.141166} = 502.77523$l. And this ſubtracted from 573.75l. leaves 70.97477l. = 70l. 19s. 6d. nearly, = the Diſcount, at Compound Intereſt.

The rule in this caſe, by logarithms, is as follows: take the logarithm of the amount of 1l. for a year, and multiply it by the time, in years, or decimal parts of a year, and ſubtract the product from the logarithm of the ſum to be diſcounted, taken decimally, and the remainder will be the logarithm of the preſent value.

Then the number in the tables anſwering thereto, is the preſent value itſelf; which, ſubſtracted from the ſaid given ſum, gives the Diſcount as before.

N. B. The moſt correct and uſeful book of logarithms, of a reaſonable price, is that of which Dr. Hutton, F. R. S. and Profeſſor of Mathematics, at the Royal Academy at Woolwich, is the author.

He has been at extreme pains in comparing, amending, and enlarging the beſt editions of Sherwin's Tables; and has alſo given, by way of introduction, a valuable hiſtory of Logarithms, with the various methods of conſtructing them, and their application, in a variety of caſes.

ARTICLE XVIII.
EQUATION OF PAYMENTS.

Definition.

Equation of Payments, is the method of finding a time, at which, if ſeveral debts, due at different periods, be all paid at once, neither party ſhall either gain or loſe thereby.

The common rule is this:

Multiply each payment by the time at which it will become due from the preſent time, or from any fixed time that ſhall not be after the firſt payment; then divide the ſum of the products by the ſum of the payments, and the quotient will be the equated time required, reckoning from the ſaid fixed time.

Example. A owes B three ſeveral ſums of money; viz. 100l. due at the end of 6 months; 500l. due at the end of 12 months; and 400l. due at the end of 15 months; what is the equated time for paying the whole?

Here $100 \times 6 = 600$; $500 \times 12 = 6000$; and $400 \times 15 = 6000$. Alſo, $600 + 6000 + 6000 = 12600$; and $100 + 500 + 400 = 1000$.

Then $\frac{12600}{1000} = 12.6$ months, or 12 months and 18 days, allowing 30 days to the month, the equated time required.

Schol. This method, though much practiſed on account of the eaſy mode of calculation, is not ſtrictly true, as it neither agrees with the principles of Simple or Compound Intereſt. However, where the whole time concerned is not long, it will deviate but very little from the truth at Simple Intereſt.

The error of this method lies in making no difference between the intereſt and the diſcount, whereas the latter is ever leſs than the former. The equated time, by the above Rule, will be always ſomething too great.

But when the period between the firſt and laſt payments is conſiderable, the equated time ſhould be aſcertained according to the principle of Compound Intereſt, as it will be inequitable if only Simple Intereſt is regarded. And, as the calculation according to Simple Intereſt is ſo very tedious that no author which I have read has given themſelves the trouble of inveſtigating a true method for more than two payments; and even for two payments none have been ſtrictly accurate, except Mr. Burrow and Mr. Bonnycaſtle; and as the method already given is ſufficient when the time between the firſt and laſt payment is not very great, it would only be introducing ſuperfluous matter to deliver any thing further on this ſubject, ſaving the Rule of Compound Intereſt, which is this:

Find the preſent value of each ſeparate payment, diſcounted at Compound Intereſt, according to the given rate of intereſt, from the time of its becoming due, to the time of the firſt payment. Then, making the ſum of all the preſent values a principal, find in how long a time, at Compound Intereſt, the ſame would amount to the ſum of the payments, and that will be the time required.

The application hereof is eaſy enough from what has been delivered in the Rules of Compound Intereſt and Diſcount, without intruding further Examples.

ART. XIX. ARITHMETICAL PROGRESSION.

Definitions.

I. An Arithmetical Progreſſion is a ſeries or rank of numbers, wherein each ſucceeding number either increaſes or decreaſes by ſome common difference.

II. The Common Difference is called the Arithmetical Ratio of ſuch Progreſſion.

III. Each number in the Progreſſion is called a Term.

IV. The Term which immediately precedes another, is named the Antecedent of that other; and that other is named the Conſequent of the preceding Term.

V. The firſt and laſt Terms of a Progreſſion are called the Extremes; and the other Terms, the Means.

Theorem I. In any even number of continued arithmetical proportionals, the ſum of the extremes is equal to the ſum of any two means that are both equally diſtant.

Thus, in the Progreſſion, 2, 4, 6, 8, 10, 12, the ſum of the extremes, viz. $12 + 2$, is equal to the ſum of any two equi-diſtant means; viz. $10 + 4$ or $8 + 6$.

Theorem II. In any odd number of continued arithmetical proportionals, the double of the middle term is equal to the ſum of any two terms that are equally diſtant.

Thus, in the Progreſſion, 1, 3, 5, 7, 9, the double of the middle term (5) is $10 = 1 + 9 = 7 + 3$.

Theorem III. The difference between any two terms in an arithmetical progreſſion is equal to the difference between any other two in that progreſſion that are at the ſame diſtance from each other.

Thus, in the ſeries 2, 5, 8, 11, 14, 17, 20, the difference between any two terms, for inſtance, between 2 and 8, is equal to the difference between any other two terms that are alike remote from each other; viz. to the difference between 5 and 11, 8 and 14, 11 and 17, and 14 and 20.

Cor. I. If there are two arithmetical ſeries, having the ſame common difference, then the difference between any two terms in the one is equal to the difference between any two terms in the other, taken at the ſame diſtance from one another in each.

Cor. II. Any ſeries which conſiſts of a conſiderable number of terms, may be reſolved into two or more ſeries, whoſe ratio or common difference ſhall be double or treble, &c. to that of the given one.

Theorem IV. If there be two ranks of numbers in arithmetical progreſſion, having the like number of terms in each, their ſum will be in arithmetical progreſſion, whoſe ratio or common difference ſhall be equal to the ſum of the ratios of the two given progreſſions.

Thus, let the 1ſt rank be 5, 7, 9, 11, 13, 15, 17, com. diff. = 2.
2d rank 3, 6, 9, 12, 15, 18, 21, com. diff. = 3.
Their ſum = 8, 13, 18, 23, 28, 33, 38, a progreſſion whoſe common difference is 5.

Theorem V. If three numbers are in Arithmetical Progreſſion, the rectangle of the extremes, together with the ſquare of the common difference, is equal to the ſquare of the middle term.

Thus, if the quantities be 4, 6, 8, the rectangle of the extremes, viz. 4×8 or 32, added to the ſquare of the common difference, viz. 4 (or 2×2) $= 32 + 4 = 36 =$ the ſquare of the middle term, viz. 6×6.

Theorem VI. The product of the ſum of the extremes, by the number of terms in any Arithmetical Progreſſion, is equal to twice the ſum of the ſum of the ſeries; and, conſequently, the ſum of the ſeries is equal to half that product.

Thus; let the ſeries be 5, 8, 11, 14, 17.

Then, $5 + 8 + 11 + 14 + 17$, or the ſum of the ſeries $= \frac{17 + 5 \times 5}{2} = \frac{22 \times 5}{2} = 11 \times 5 = 55$.

Cor. I. Twice the ſum of any arithmetical ſeries, divided by the ſum of the extremes, is equal to the number of terms.

Cor. II. Twice the ſum of the ſeries, divided by the number of terms, is equal to the ſum of the extremes; and, therefore, if one extreme is given, the other is had by Subtraction.

Theorem VII. In any arithmetical ſeries, the laſt term in an increaſing progreſſion, or the firſt term in a decreaſing one, is equal to the ſum of the other extreme, and the product under the number of terms, leſs 1, and the common difference.

Thus; let the ſeries be 3, 6, 9, 12, increaſing; or 12, 9, 6, 3, decreaſing.

Then $3 + 9$ (or 3×3) $= 12 =$ the laſt term in the former, or the firſt term in the latter ſeries.

Theorem VIII. In any arithmetical ſeries, the firſt term in an increaſing progreſſion, or the laſt in a decreaſing one, is equal to the difference between the other extreme; and the product under the number of terms, leſs 1, and the common difference.

Thus, in the foregoing ſeries, $12-9=3$, the firſt term in the increaſing progreſſion, and the laſt in the decreaſing one.

Cor. I. The ratio, or common difference, is equal to the difference of the extremes, divided by the number of terms, leſs 1.

Cor. II. The quotient produced by dividing the difference of the extremes by the ratio, or common difference, is equal to the number of terms, leſs 1; and, conſequently, the ſaid quotient, more 1, is equal to the number of terms.

Theorem IX. If the roots of a ſeries of ſquare, cube, biquadrate, &c. numbers, are in arithmetical progreſſion, the 2d, 3d, 4th, &c. differences of ſuch ſquare, cube, biquadrate, &c. numbers, reſpectively, are equal.

Roots	1,	3,	5,	7,	9						
Squares	1,	9,	25,	49,	81	1ſt diff.	8,	16,	24,	32	
						2d diff.		8,	8,	8	equal.
Cubes	1,	27,	125,	343,	729	1ſt diff.	26,	98,	218,	386	
						2d diff.	—	72,	120,	168	
						3d diff.	—	—	48,	48	equal.

QUESTIONS IN ARITHMETICAL PROGRESSION.

Question I. A maſter hires a ſervant for 6 weeks, and agrees to pay him for the firſt day, two pence, for the ſecond, four pence, for the third, ſix pence, and ſo on, advancing his wages two pence per day. What is the amount of the ſix weeks wages?

Here the firſt term is 2, the ratio 2, and the number of terms 42. And, by Theorem VII. the laſt term is $\overline{41\times 2}+2=82+2=84$.

Alſo, by Theorem VI. $\frac{\overline{84+2}\times 42}{2}=$ ſum of the ſeries $=86\times 21=1806$ pence $=$ 7 l. 10 s. 6 d. the Anſwer.

Question II. A perſon undertakes to walk 400 miles; and to walk 31 miles the firſt day, and encreaſe each day's journey by a certain conſtant portion, in ſuch ſort, that the laſt day's journey ſhall be 49 miles. It is required to determine how long he will be in performing this undertaking, and what will be the increaſe wherewith he will daily mend his pace?

Here there is given the ſum of the ſeries, and the extremes.

And, by Theorem VI. Cor. I. $\frac{400\times 2}{31+49}=\frac{800}{80}=10=$ the number of days he would be on his journey: alſo, by Theorem VIII. Cor. I. $\frac{49-31}{10-1}=\frac{18}{9}=2$, the miles he walked each day more than on the preceding day.

Question III. A perſon paid off, by inſtalments, a certain debt; the firſt payment was 20 s. the next 25 s. the next 30 s. and ſo on; increaſing the payments each time by 5 s. Now the laſt payment was 10 guineas. I demand what was the debt, and in how many payments the ſame was diſcharged?

By Theorem VIII. Cor. II. the number of payments is $=\frac{210-20}{5}+1=\frac{190}{5}+1=38+1=39$. Then, by Theorem VI. the debt is $=\frac{\overline{210+20}\times 39}{2}=\frac{230\times 39}{2}=115\times 39$ $=4485$ ſhillings $=$ 224 l. 5 s.

A SYNOPSIS OF THE DIFFERENT CASES IN ARITHMETICAL PROGRESSION.

Caſe	Given.	Required.	Solution.
1	*a, d, n,*	*l, s,*	$l=a+\overline{n-1}\times d$ $s=na+\overline{n-1}\times\frac{1}{2}nd$
2	*a, d, l,*	*n, s,*	$n=\frac{l-a}{d}+1$ $s=\frac{\overline{l-a+d}\times\overline{l+a}}{2d}$
3	*a, l, s,*	*d, n,*	$d=\frac{\overline{l+a}\times\overline{l-a}}{2s-l-a}$ $n=\frac{2s}{l+a}$
4	*a, n, s,*	*d, l,*	$d=\frac{2s-2na}{\overline{n-1}\times n}$ $l=\frac{2s}{n}-a$
5	*a, n, l,*	*d, s,*	$d=\frac{l-a}{n-1}$ $s=\frac{a+l}{2}\times n$
6	*s, n, d,*	*a, l,*	$a=\frac{s}{n}-\frac{n-1}{2}\times d$ $l=\frac{s}{n}+\frac{n-1}{2}\times d$
7	*a, d, s,*	*n, l,*	$n=\frac{\sqrt{\overline{2a-d}\,\vert^{2}+8ds}-\overline{2a-d}}{2d}$ $l=\frac{\sqrt{\overline{2a-d}\,\vert^{2}+8ds}-d}{2}$
8	*d, n, l,*	*a, s,*	$a=l-\overline{n-1}\times d$ $s=\frac{2l-nd+d}{2}\times n$
9	*d, l, s,*	*a, n,*	$a=\frac{d\pm\sqrt{\overline{2l+d}\,\vert^{2}-8ds}}{2}$ $n=\frac{2l+d\mp\sqrt{\overline{2l+d}\,\vert^{2}-8ds}}{2d}$
10	*l, n, s,*	*a, d,*	$a=\frac{2s}{n}-l$ $d=\frac{2nl-2s}{\overline{n-1}\times n}$

Note in the above.
$a=$ leaſt term.
$l=$ greateſt term.
$n=$ number of terms.
$d=$ common difference.
$s=$ ſum of the ſeries.

ARTICLE XX.

OF FIGURATE OR POLYGONAL NUMBERS.

Definitions.

I. The ſums of numbers in a continued arithmetic proportion from unity, are called Figurate or Polygonal Numbers.

II. The ſeveral ſums of a ſeries of Figurate Numbers, are called Solid Figurates or Pyramids. Alſo, the ſums of the Pyramids are named Second Pyramidals; Pyramidals, the Sums of Second Pyramidals, Third Pyramidals; and ſo on.

Arithmetical Series.	Diff. 1.	Diff. 2.	Diff. 3.	Diff. 4.
	1, 2, 3, 4, &c.	1, 3, 5, 7, &c.	,4, 7, 10, &c.	1, 5, 9, 13, &c.
Figurates of the	Triangulars.	Squares.	Pentagonals.	Hexagonals.
Firſt order	1, 3, 6, 10	1, 4, 9, 16	1, 5, 12, 22	1, 6, 15, 28
Second order	1, 4, 10, 20	1, 5, 14, 30	1, 6, 18, 40	1, 7, 22, 50
Third order	1, 5, 15, 35	1, 6, 20, 50	1, 7, 25, 65	1, 8, 30, 80

Note. All the figurate orders of the ſeries, 1, 2, 3, 4, &c. where the difference is 1, are of the triangular kind; becauſe the units of each number in the firſt order (after the firſt) may be regularly diſpoſed in a triangular form; viz. trees, or any other things to the amount of thoſe numbers, may be ſo diſpoſed. Alſo, all the orders of the ſeries, 1, 3, 5, 7, where the difference is 2, are of the ſquare kind, becauſe the numbers in the firſt order form ſquares: and all the orders of the ſeries, 1, 4, 7, 10, where the difference is 3, are of the pentagon kind, becauſe the numbers in the firſt order form pentagons; where the difference is 4, they are of the hexagon kind; and, in general, all the orders of any ſeries are denominated after the name of that polygon whoſe number of ſides or angles exceed the common difference by 2.

Note alſo, The number of terms compoſing any figurate number of the firſt order, ſhews the number of units to be diſpoſed on each ſide of the polygon to which it relates.

Problem I. Given the ſide or number of terms compoſing any figurate of the firſt order, and the common difference of the arithmetical ſeries from which it is derived, to find the figurate number.

Rule. Multiply the ſide or number of terms, leſs 1, by half the product under the ſide and common difference; to the reſult add the ſaid ſide, and it will be the Anſwer required.

Example. Let the common difference of the arithmetical ſeries be 4, and the number of terms 10; what is the figurate number?

Here $10+\overline{10-1}\times\frac{4\times 10}{2}=10+9\times 2\times 10=10+180=190$, the figurate number required.

Cor. I. Since a figurate number of this order is $=$ to the ſum of all the given number of terms in the arithmetical ſeries, it follows, that this caſe is equivalent to the finding of the ſum of an arithmetic ſeries proceeding from unity, the common difference and number of terms being given.

Cor. II. If the number of the ſides or angles of the polygon, inſtead of the common difference of the arithmetical ſeries had been given, the caſe would have been the ſame, ſince the number of ſides or angles, leſs 2, is $=$ common difference.

Problem II. Given a figurate number of the firſt order, and the common difference of the arithmetical ſeries, to find the ſide, or number of terms compoſing it.

Rule. To 8 times the given number, add the common difference, and from the ſum ſubtract 4; then multiply the remainder by the difference, add 4 to the product, divide the ſum by 4 times the ſquare of the difference, and extract the ſquare root of that quotient. Alſo take the difference between 2, and the common difference, and divide the ſame by twice the difference; then, if the common difference was above 2, the quotient thus obtained muſt be added to, but, if leſs, ſubtracted from, the ſaid ſquare root, and the reſult will be the Anſwer.

If the common difference be 2, the ſquare root itſelf is the Anſwer.

Example. Let the figurative number be 190, and of the hexagon kind, what number of terms is it compoſed of, or what term is it in the figurate rank?

Here $6 =$ number of ſides, and $6 - 2 = 4$, the common difference. Alſo $190 \times 8 + 4 - 4 = 1520$.

And $\frac{1520 \times 4 + 4}{4 \cdot 4^2} = \frac{1520 + 1}{4^2} = \frac{1521}{4 \times 4} = \frac{380.25}{4} = 95.0625$.

Then $\sqrt{95.0625} = 9.75$. Likewiſe $\frac{4-2}{2 \times 4} = \frac{2}{8} = \frac{1}{4} = .25$; and $9.75 + .25 = 10$, the Anſwer ſought.

Cor. I. This caſe amounts to the ſame thing, as finding the number of terms in an arithmetic ſeries, proceeding from unity; by having the ſum of the ſeries, and the ratio or common difference given.

Prob. III. To find any aſſigned term of a triangular ſeries of any given order.

Rule. Let *n* denote the place of the term in the ſeries, and *m* the number expreſſing the given order; then, if as many terms of the following ſeries, as is denoted by $m + 1$, be multiplied together, the reſult will be the Anſwer.

Note alſo, the denominator of the laſt term, included in the operation, is always $= n$.

The ſeries, $n, \frac{n+1}{2}, \frac{n+2}{3}, \frac{n+3}{4}, \frac{n+5}{6}, \frac{n+6}{7}$, &c. *ad infinitum.*

Example. What is the 6th term of a ſeries of the 5th order of the triangular kind?

Here $n = 6$; and $m = 5$; and therefore the number of terms to be multiplied $= 5 + 1 = 6$.

Conſequently, $6 \times \frac{7}{2} \times \frac{8}{3} \times \frac{9}{4} \times \frac{10}{5} \times \frac{11}{6} . = \frac{6 \times 7 \times 8 \times 9 \times 10 \times 11}{2 \times 3 \times 4 \times 5 \times 6}$ $= \frac{7 \times 2 \times 9 \times 2 \times 11}{6} = 7. \times 2 \times 3 \times 11 = 462$, the Anſwer.

Cor. The ſum of *n* terms, in any order, is equal to the *n*th term in the next ſuperior order. Hence, the above Anſwer, is equal to the ſum of 6 terms in the 4th order?

Problem IV. To find the figurate number in any place of any order, and of what ſpecies ſoever the polygon is of.

Rule. Find by the laſt Problem the figurate number, in the given place, and order, of the triangular ſpecies; alſo find the figurate number, in the preceding place of the ſaid order and ſpecies; and multiply the ſame by the number of the order, leſs 1; to the product, add the firſt found figurate number, and the ſum will be the Anſwer ſought.

Example. Let it be required to find the fourth term in the ſeries of the 3d order of pentagonals.

Here $n = 4$; and $m = 3$; and, therefore, the fourth term in the triangular ſeries $= 4 \times \frac{4+1}{2} \times \frac{4+2}{3} \times \frac{4+3}{4}, = \frac{4 \times 5 \times 6 \times 7}{2 \times 3 \times 4} = 5 \times 7 = 35$. And the preceding term in that order, &c. $= \frac{3 \times 4 \times 5 \times 6}{2 \times 3 \times 4} = 3 \times 5 = 15$. Then $15 \times \overline{3 - 1} = 15 \times 2 = 30$, and $30 + 35 = 65$, the Anſwer.

Cor. The like remark takes place here as in the preceding Problem, ſo that this Anſwer is equal to the ſum of 4 terms of the ſeries in the 2d order of pentagonals, or the 2d order of the 3d ſpecies of figurates.

ART. XXI. GEOMETRICAL PROGRESSIONS.

Definitions.

I. Any ſeries of numbers increaſing by a conſtant multiplication, or decreaſing, by a conſtant diviſion, is ſaid to be in geometrical progreſſion, thus; 2, 4, 8, 16, 32, &c. is an increaſing ſeries by a continual multiplication by 2, and 81, 27, 9, 3, 1, &c. is a decreaſing ſeries by a conſtant diviſion by 3.

II. The number, by which the ſeries is conſtantly multiplied, or divided, is called the ratio.

III. Duplicate, triplicate, quadruplicate, &c. ratio, is the ſquare, cube, biquadrate, &c. of ſome given ratio.

IV. The greateſt and leaſt terms are called the extremes, and the intermediate terms the means.

V. The antecedent of any term, is that term which immediately precedes it; and the conſequent of any term, is that term which follows next in order after it.

Theorem I. In any ſeries of numbers, in geometrical progreſſion, the product of the extremes is equal to the product of any two means equally diſtant from the extremes. Thus, in the geometric progreſſion, 3, 6, 12, 24, 48, 96, the product of the extremes, viz. 3×96 (or 108) $= 6 \times 48 = 12 \times 24$.

Cor. In a ſeries where the number of terms is odd, the product of the extremes is alſo equal to the ſquare of the middle term.

Theorem II. If out of any geometric ſeries, there be taken any ſeries of equidiſtant terms, that ſeries will alſo be in geometric progreſſion.

Thus in the ſeries 1, 3, 9, 27, 81, 343, 1029, &c. there be taken the terms, 3, 27, 343, theſe terms are alſo in geometrical progreſſion, and are in the triplicate ratio of the former.

Cor. Hence, any geometric ſeries, where the number of terms is conſiderable, may be reduced in two or more other ſeries.

Theorem III. If there be a ſeries of terms in geometric progreſſion, their reſpective differences will alſo be in the ſame geometric progreſſion. Thus, in the ſeries 1, 3, 9, 27, 81, 343, &c. the differences $3 - 1$, $9 - 3$, $27 - 9$, $81 - 27$, &c. $= 2, 6, 18, 54$, reſpectively, are in the ſame geometric progreſſion with the given ſeries, viz. the ratio in both progreſſions is the ſame.

Cor. Hence, the differences of theſe differences; and again, the differences of theſe latter differences, will be in the ſame geometric progreſſion.

Theorem IV. The laſt term in any deſcending geometric ſeries, or the firſt term in any aſcending one, is equal to the other extreme divided by the ratio, raiſed to the power denoted by the number of terms, leſs 1.

Thus, in the ſeries 2, 6, 18, 54, aſcending; or 54, 18, 6, 2, deſcending; the firſt term in the former, or laſt in the latter, is equal to 54 divided by the cube of the ratio, viz. by 3^3, or 27; $= \frac{54}{27} = 2$.

Cor. I. The laſt term in any aſcending ſeries, or the 1ſt in any deſcending one, is equal to the other extreme, multiplied by the ratio, raiſed to the power, denoted by the number of terms, leſs 1.

Cor. II. In general the *n*th term of an aſcending ſeries, is equal to the firſt term, multiplied by r^{n-1}; where *r* is put to denote the ratio.

Cor. III. The *n*th term of any deſcending ſeries, is equal to the firſt term, divided by r^{n-1}.

Theorem V. In any geometric ſeries, whether aſcending or deſcending, the difference between the ſquare of the firſt term, and the product of the ſecond and laſt, divided by the difference between the firſt and ſecond terms, is equal to the ſum of all the ſeries.

Thus in the aſcending ſeries 2, 4, 8, 16, 32, the ſquare of the firſt term (2) is 4; the product of the ſecond and laſt $= 4 \times 32 = 128$; and $128 - 4 = 124$. Alſo the difference between the firſt and ſecond terms $= 4 - 2 = 2$; and $\frac{124}{2} = 62$, the ſum of the ſeries.

Again, in the deſcending ſeries 32, 16, 8, 4, 2, the ſquare of the firſt term (32) is $32 \times 32 = 1024$; the product of the ſecond and laſt $= 16 \times 2 = 32$; and $1024 - 32 = 992$. Alſo the difference between the firſt and ſecond terms $= 32 - 16 = 16$; and $\frac{992}{16} = \frac{248}{4} = 62$, the ſum of the ſeries, as before.

Cor. I. Or, if the difference between the firſt and laſt terms be divided by the difference between the firſt and ſecond terms, and the quotient be multiplied by the ſecond term; then this product, added to the firſt term, will be the ſum of the ſeries, whether the ſame be an aſcending or deſcending one.

Cor. II. If the greateſt term of any geometric ſeries, be multiplied by the ratio; and, if from the product, the leaſt term be ſubtracted, and the remainder divided by the ratio, leſs 1, the quotient will be the ſum of the ſeries.

Cor. III. If in any geometric ſeries, the difference between the greateſt and leaſt terms, be divided by the ratio, leſs 1; and, if the quotient be added to the greateſt term, the reſult will be the ſum of all the ſeries.

Cor. IV. If the ratio of any geometric ſeries, be raiſed to the power denoted by the number of terms, and 1 be ſubtracted therefrom; and, if this remainder be divided by the ratio, leſs 1, and the quotient be multiplied by the leaſt term, the product will be the ſum of the ſeries.

Cor. V. If the ratio of any geometric ſeries, be raiſed to the power denoted by the number of terms, and 1 be ſubtracted therefrom; and, if this remainder be divided by the next inferior power of the ratio, or by the ratio raiſed to the power, denoted by the number of terms, leſs 1, and this quotient be multiplied by the greateſt term, the product will be the ſum of all the ſeries.

Cor. VI. In any infinite decreaſing geometric progreſſion, if the ſquare of the firſt term be divided by the difference between the firſt and ſecond terms, the quotient will be the ſum of the ſeries.

Cor. VII. If in any infinite decreaſing geometric progreſſion, the product of the firſt and ſecond terms be divided by the difference of thoſe terms, and the quotient added to the firſt term, the reſult will be equal to the ſum of the ſeries.

Cor. VIII. If in any infinite decreaſing geometric progreſſion, the firſt term be multiplied by the ratio, and the product be divided by the ratio, leſs 1, then the quotient will be the ſum of the ſeries.

Cor. IX. If the ſum of an infinite decreaſing geometric progreſſion, be divided by the difference between the ſum and the firſt term, the quotient will be the ratio of ſuch ſeries.

Cor. X. If the ſum of an infinite decreaſing geometric progreſſion, be divided by the ratio, and the quotient ſubtracted from the ſaid ſum, or multiplied by the ratio, leſs 1, the remainder in the former caſe, or the product in the latter, will be the firſt term.

N. B. Moſt of the operations in geometric progreſſion, are beſt wrought by logarithms; as through their uſe, Multiplication is performed by Addition; Diviſion, by Subtraction; Involution, by Multiplication; and Evolution, by Diviſion.

QUESTIONS IN GEOMETRIC PROGRESSION.

Question I. What debt will be diſcharged in 9 months, by paying 3 l. the firſt payment, 6 l. the ſecond, 12 l. the third, and ſo on, doubling the payment each time; and what will be the laſt payment?

Here, by Theorem V. Cor. IV. $\frac{2^9-1}{2-1}\times 3=$ the debt $=\overline{2^9-1}\times 3$; alſo, $2^9=2\times2\times2\times2\times2\times2\times2\times2\times2=512$; and therefore $512\times3=1533$ l. the debt.

And, by Theorem IV. Cor. I. $2^8\times3=$ laſt payment $=256\times3=768$ l.

Question II. What debt will be diſcharged by monthly payments in geometric progreſſion, the firſt payment being 1 l. and the laſt 2048 l. the ratio being 2?

Here, by Cor. III. $\frac{2048-1}{2-1}+2048=2047+2048=4095$ l. the Anſwer.

Question III. Suppoſe a body to move perpetually after this manner; viz. the firſt year 20 miles, the ſecond, 19 miles, the third, $18\frac{1}{20}$, and ſo on, in a geometric progreſſion, whoſe ratio is $\frac{20}{19}$, how far will it move in an eternity, or what is the diſtance beyond which it can never paſs?

Here, by Theorem V. Cor. VIII. $20\times\frac{20}{19}\div\frac{1}{19};=\frac{20\times20\times19}{19}=20\times20=400$ miles, the diſtance required.

A SYNOPSIS OF THE DIFFERENT CASES IN GEOMETRIC PROGRESSION.

Caſe	Given	Required.	Solution.
1	*a*, *r*, *n*,	*l*, *s*,	$l=ar^{n-1}$ $s=\frac{r^n-1}{r-1}\times a$
2	*a*, *r*, *l*,	*s*, *n*,	$s=\frac{l-a}{r-1}+l$ $n=\frac{\log.\,l-\log.\,a}{\log.\,r}+1$
3	*a*, *r*, *s*,	*l*, *n*,	$l=s-\frac{s-a}{r}$ $n=\frac{\log\,\overline{\overline{r-1}\times s+a}-\log.\,a}{\log.\,r}$
4	*a*, *l*, *s*,	*r*, *n*,	$r=\frac{s-a}{s-l}$ $n=\frac{\log.\,l-\log.\,a}{\log.\,\overline{s-a}-\log.\,\overline{s-l}}+1$
5	*a*, *n*, *s*,	*r*, *l*,	*r*, will be had by ſolving this equation, viz. $-r^n+\frac{rs}{a}=\frac{s-a}{a}$; and *l*, will be had by ſolving this equation, $l\times\overline{s-l}\vert^{n-1}=a\times\overline{s-a}\vert^{n-1}$
6	*a*, *n*, *l*,	*r*, *s*,	$r=\overline{\frac{l}{a}}\vert^{\frac{1}{n-1}}$ $s=\frac{l-a}{\overline{l\div a}\vert^{\frac{1}{n-1}}-1}+l$
7	*r*, *n*, *l*,	*a*, *s*,	$a=\frac{l}{r^{n-1}}$ $s=\frac{r^n-1}{r-1}\times\frac{l}{r^{n-1}}$
8	*r*, *n*, *s*,	*a*, *l*,	$a=\frac{r-1}{r^n-1}\times s$ $l=\frac{sr^{n-1}}{r^n-1}\times\overline{r-1}$
9	*r*, *l*, *s*,	*a*, *n*,	$a=rl-\overline{r-1}\times s$; or $s-\overline{s-l}\times r$ $n=\frac{\log.\,l-\log.\,\overline{s-\overline{s-l}\times r}}{\log.\,r}+1$
10	*n*, *l*, *s*,	*a*, *r*,	*a*, will be had by ſolving this equation, viz. $a\times\overline{s-a}\vert^{n-1}=l\times\overline{s-l}\vert^{n-1}$; and *r* will be had by this equation, viz. $-r^n+\frac{s}{s-l}r^{n-1}=\frac{l}{s-l}$

Note, in the above Synopſis,
$a=$ leaſt term.
$l=$ greateſt term.
$s=$ ſum of the ſeries.
$n=$ number of terms.
$r=$ ratio.

ART. XXII. OF HARMONIC PROPORTION.

Definitions.

I. When three terms are ſo diſpoſed that the difference between the firſt and ſecond is to the difference between the ſecond and third, as the firſt term is to the third, they are ſaid to be harmonically proportional.

II. When four terms are ſo diſpoſed, that the difference between the firſt and ſecond is to the difference between the third and fourth, as the firſt term is to the fourth, they are alſo harmonically proportional.

III. If the terms of an harmonic proportion be continued, then it is called an Harmonic Progreſſion.

Problem I. Given two terms to find a third in harmonic proportion.

Rule. Divide the product of the two terms by the difference between twice the firſt and ſecond term, and the quotient will be the third term of the proportion; but if it be the ſecond and third term that is given, and the firſt term is wanted, then divide their product by the difference between twice the third term and the ſecond, and the quotient will be the firſt term.

Note. The firſt or third term (according as the caſe ſhall be propoſed) muſt be greater than half the ſecond, otherwiſe the queſtion will be impoſſible.

Example. Let the firſt and ſecond terms be 10 and 15, reſpectively, what is the third term in an Harmonic Proportion?

Here $\frac{10\times15}{20-15}=\frac{10\times3}{4-3}=30$, the Anſwer.

Problem II. Given three terms to find a fourth in harmonic proportion.

Rule I. If the three firſt terms be the firſt, ſecond, and third, then divide the product of the firſt and third by the difference between twice the firſt term and the ſecond term, and the quotient will be the fourth term of the proportion.

Note. Here the firſt term muſt be propoſed greater than half the ſecond, or the caſe will be impoſſible.

II. If the given terms be the ſecond, third, and fourth, to find the firſt, then divide the product of the ſecond and fourth by the difference between twice the fourth term and the third, and the quotient will be the firſt term.

Here the fourth term muſt be greater than half the third.

Example. Let the ſecond, third and fourth terms be 16, 24, and 60, reſpectively, what is the firſt term?

Here $\frac{16\times60}{120-24}=\frac{16\times5}{10-2}=\frac{8\times5}{5-1}=\frac{40}{4}=10$, the Anſwer.

ART. XXIII. THE RULE OF FALSE POSITION.

Definitions.

I. This Rule is called Falſe Poſition, becauſe by a Poſition or Suppoſition of falſe numbers, it teaches how to obtain the true Anſwer.

II. Queſtions which come under this Rule are ſuch as cannot be eaſily ſolved by the common rules, and are of two ſorts, ſome requiring the ſuppoſition of only one falſe number, and others requiring two.

III. Where one ſuppoſition only is uſed, the method is called Single Poſition; where two ſuppoſitions are made, it is named Double Poſition.

In caſes where the reſults are proportional to their ſuppoſitions, the Single Rule will give the Anſwer.

THE RULE FOR SINGLE POSITION.

Suppoſe ſome fit number at pleaſure to denote the Anſwer, and try according to the tenor of the queſtion, whether the ſame be true or falſe. If it anſwer the conditions of the queſtion, you have hit upon the right number; but if not, you muſt obſerve what the falſe reſult or concluſion is. Then ſay by the Rule of Three, As the falſe concluſion is to the true number given, ſo is the falſe ſuppoſition to the true Anſwer.

Question. A gentleman dying left 10000 l. among his three ſons, A, B, C, in ſuch proportion, that A's part ſhould be one ſixth of B's part, and B's part five ſixths of C's part. What was the ſhare of each?

Suppoſe A's part = 500 l. then B's = 3000 l. and C's = 2500 l. their ſum is 6000 l. which ſhould have been 10000 l. therefore, As 6000 l. : 10000 l. :: 500 l. to A's part $=\frac{5000000}{6000}=\frac{5000}{6}=$ 833 l. 6 s. 8 d. and, conſequently, B's ſhare = 5000 l. and C's = 4166 l. 13 s. 4 d. which together make 10000 l.

THE RULE FOR DOUBLE POSITION.

Suppoſe two fit numbers, and proceed with each, as the conditions of the queſtion direct; then, if either of the numbers ſo taken ſhall anſwer all the conditions, you have hit upon the true Anſwer; but, if not, obſerve what the errors are; viz. how much is the exceſs or defect of each ſuppoſition, writing the ſuppoſitions one under another, with their errors oppoſite to them. This done, multiply the numbers croſswiſe; viz. the firſt ſuppoſition by the laſt error, and the laſt ſuppoſition by the firſt error; then, if the ſuppoſitions are of different kinds, viz. one greater than the truth, and the other leſs, divide the ſum of thoſe products by the ſum of the errors; but, if the ſuppoſitions are alike, viz. either both greater or both leſs than the truth, divide the difference of the products by the difference of the errors; ſo will the quotient in either caſe be the Anſwer required.

Or, you may proceed to find a correction to be added to either ſuppoſition. Thus ſay, as the difference of the errors, if alike, or ſum, if they are unlike, is to the difference of the ſuppoſitions, ſo is either error to the correction to be added to or ſubtracted from the ſuppoſition to which it belongs, according as the ſame was leſs or greater than the truth. And here, in order to prevent miſtakes, it will be proper, when a ſuppoſition is leſs than the truth, to annex thereto the ſign (+) to ſhew that the correction is to be added; and, when greater, the ſign (—) to denote that the correction is to be ſubtracted.

Question I. Two perſons, A and B, were diſcourſing of their money; A ſaid to B, give me 5 guineas of your money, and I ſhall have juſt as much as you. No, replied B to A, rather give me 5 guineas of your money, and I ſhall have juſt three times as much as you. How much money had each?

Here, ſuppoſe A had 10 guineas; then, according to the firſt condition of the queſtion, B muſt have had 20; then, by the ſecond condition, if A give B 5 guineas, A will have 5, and B 25; but thrice A's, viz. 15, ſhould have been equal to B's; therefore, this ſuppoſition of A's money comes ſhort by 10.

Again: Suppoſe A had 18 guin. then, according to the firſt condition, B muſt have had 28; and, by the ſecond condition, if 5 be taken from A's and put to B's money, A will have 13 guineas, and B 33 guineas. But thrice A's, in this caſe, (viz. 39) ſhould be juſt equal to B's. Wherefore this ſuppoſition exceeds the truth by 6. So I write down the ſuppoſitions with their errors, and proceed as under.

1ſt Method.

$$\begin{array}{lccc} & & \text{Error.} & \\ \text{1ſt Suppoſ.} & 10 & 10 & \\ \text{2d Suppoſ.} & \underline{18} & \underline{6} & \Big\}\,16 \\ \text{Prod.} & 180 & 60 \text{ Prod.} & \\ \text{Add} & \underline{60} & & \\ 16\,) & 240 & (\,15 \text{ Anſwer.} & \\ & \underline{16} & & \\ & 80 & & \\ & \underline{80} & & \\ & .. & & \end{array}$$

2d Method.

$$\begin{array}{lccc} & & & \text{Error.} \\ \text{1ſt Suppoſ.} & 10 & + & 10 \\ \text{2d Suppoſ.} & \underline{18} & - & \underline{6} \\ \text{Difference} & 8 & & 16 \text{ Sum.} \end{array}$$

Then, as 16 : 8 :: 6 : 3, the Cor.
And 18 — 3 = 15, the Anſ.
Or, as 16 : 8 :: 10 : 5, the Cor.
And 10 + 5 = 15, the Anſ.

Question II. A and B, working together on the ſame work, can earn 40 ſhillings in ſix days; A and C together can earn 54 ſhillings in 9 days; and B and C 80 ſhillings in 15 days. It is required to determine, what each perſon, alone, can earn per day?

Here, ſuppoſe A can earn 3 ſhillings per day; then it is plain that B muſt earn 22 ſhillings in 6 days, and C muſt earn 54 ſhillings in 9 days, or as much as A; wherefore, B and C together will, at this rate, earn 100 ſhillings in 15 days, which is 20 ſhillings more than is allotted to them by the queſtion; and, as it is evident that the wages of B and C will decreaſe when thoſe of A are increaſed, it follows, that the value of A's wages has been aſſumed too ſmall. Wherefore, for a ſecond ſuppoſition, ſuppoſe A's wages to be 4 ſhillings per day, then B muſt earn 16 ſhillings in 6 days, and C 18 ſhillings in 9 days; and, therefore, B and C together would earn 70 ſhillings in 15 days, which is 10 ſhillings too little; and therefore the ſuppoſition of 4 ſhillings a day for A is too much.

Hence the following operation:

By 1ſt Method.

$$\begin{array}{lccc} & & \text{Error.} & \\ \text{1ſt Suppoſ.} & 3 & 20 & \\ \text{2d Suppoſ.} & \underline{4} & \underline{10} & \Big\}\,30 \\ \text{Prod.} & 80 & 30 \text{ Prod.} & \\ \text{Add} & \underline{30} & & \\ 3|0\,) & \underline{11|0} & & \\ & 3\text{s. } 8\text{d. Anſwer.} & & \end{array}$$

Or thus, by 2d Method.

$$\begin{array}{lccc} & & & \text{Error.} \\ \text{1ſt Suppoſ.} & 3 & + & 20 \\ \text{2d Suppoſ.} & \underline{4} & - & \underline{10} \\ \text{Difference} & 1 & & 30 \text{ Sum} \end{array}$$

As 30 : 1 :: 20 : $\frac{2}{3}$s. = 8d.
which, added to 3, gives 3s. 8d.

So it appears, that A can earn 3s. 8d. per day, or 22 ſhillings in 6 days; and therefore, B muſt earn 18 ſhillings in 6 days, or 3 ſhillings per day; and C muſt earn 21 ſhillings in nine days, or 2s. 4d. per day; and, conſequently, B and C together will earn 80 ſhillings in 15 days, agreeably to the queſtion, which proves the Anſwer to be true.

It will be needleſs to give more Examples, as thoſe who underſtand the above will find no difficulty in any other.

ARTICLE XXIV.

OF PERMUTATION AND COMBINATION, &c. OF QUANTITIES.

Definitions.

I. The Permutation of Quantities, is the ſhewing how many different ways the diſpoſition or order of any given number of things may be changed. This is alſo called Variation, Alternation, or Changes.

II. The Combination of Quantities, is the ſhewing how often a leſs number of quantities or things can be taken out of a greater, and combined together, without conſidering their places, or the order they ſtand in. This is ſometimes called Election or Choice.

Note. Here every parcel muſt be different from all the reſt; and no two are to have preciſely the ſame Quantities or Things.

III. The Compoſition of Quantities, is the taking a given number of quantities out of as many equal rows of different quantities, one out of every row, and combining them together.

Here no regard is had to their places, and it differs from Combination, in which there is but one row of things.

IV. Combinations of the ſame form, are thoſe wherein there are the ſame number of quantities, and the ſame repetitions: as *a b c c*, *b b a d*, *e f f g*, &c. are of the ſame form. Alſo, $A\,B^3\,C^2$, $D\,A^2\,E^3$, $C^3\,E\,D^2$, &c. are of the ſame form. But, $A\,B^2\,C$, $A\,B^3$, $A^2\,C^2$, &c. are of different forms.

Here obſerve, when any quantity is written with an index at the top, it denotes ſo many repetitions of that quantity; thus a^2 ſignifies *a a*, a^3, *a a a*, &c.

Problem I. To find the number of Permutations or Changes of any given number of things, all different from one another.

Rule. Multiply all the terms of the natural ſeries of numbers, (viz. 1, 2, 3, 4, 5, 6, 7, &c. from 1, up to the given number, continually together, and the laſt product will be the Anſwer required.

Example I. How many changes can be rung upon 8 bells?

Here $1\times2\times3\times4\times5\times6\times7\times8 = 40320$, the Anſwer.

Example II. How many days can 7 perſons be placed in a different poſition at dinner?

Here $1\times2\times3\times4\times5\times6\times7=5040$ days, or 13 yrs. 41 weeks, and 5 days, ſuppoſing three leap years to fall within that period.

Problem II. Any number of things being given to find how many changes can be made out of them, by taking any propoſed number of quantities at a time?

Rule. Take as many terms of a ſeries of numbers, beginning at the number of things given, and decreaſing by 1, as is denoted by the number of quantities to be taken at a time, and multiply them into one another, and the product will be the Anſwer.

Example. How many changes can be rung with four bells, out of eight?

Here $8\times7\times6\times5 = 1680$, the Anſwer.

Problem III. Any number of things being given, whereof there is a certain given quantity of things of one ſort, and a certain given quantity of another, &c. to determine how many changes can be made out of them all?

Rule. Let m denote the whole number of things; alſo, let p denote the number of one ſort, and q the number of things of another ſort, &c. then $\frac{1\times2\times3\times4\times5,\ \&\text{c. to } m \text{ terms}}{1\times2\times3,\&\text{c. to } p \text{ ter.}\times1\times2\times3,\&\text{c. to } q \text{ ter.}\&\text{c.}}$ will be the Anſwer required.

Example. How many different numbers can be made out of the following figures, 1220005555?

Here, the whole number (or m) = 10; alſo, there being one 1, two 2's, three 0's, and four 5's, the Anſwer will be exhibited as follows; viz. $\frac{1\times2\times3\times4\times5\times6\times7\times8\times9\times10}{1.\times\overline{1\times2}.\times\overline{1\times2\times3}.\times\overline{1\times2\times3\times4}} = 1260$, the Anſwer.

Problem IV. To find the changes of any given number of things, taken a given number at a time, in which there are ſeveral things of one ſort, ſeveral of another, &c.

Rule. Find all the different forms of Combination of all the given things, taking as many at a time as is ſpecified in the queſtion: alſo find the number of changes in any form, and multiply it by the combinations in that form. Do the ſame for each diſtinct form, and the ſum of all the products will give the whole ſum of the changes required.

Note. All the difficulty here, is to find the combinations required, and this is eaſily done when the quantities are but few, by joining together every two, every three, &c. till you come at the given number to be taken at a time, and then reckoning how many different forms there are, having the given number at a time, and how many in each form. But when the quantities are many, and often repeated, this method will be impracticable; ſo that recourſe muſt then be had to Problem VI. following, to find theſe Combinations?

Example. How many changes can be made of every four letters out of theſe eight; viz. *a a a b b b c c*?

Set down the quantities as though you were going to multiply them in an algebraical manner, and note down all the products accordingly, except ſuch as happen to be the ſame as ſome of the foregoing, and ſuch as are out of the queſtion.

a, *b*, *c*,
a, *b*, *c*,
aa, *ab*, *ac*, *bb*, *bc*, *cc*,
a, *b*, *c*,
aaa, *aab*, *aac*, *abb*, *abc*, *acc*, *bbb*, *bbc*, *bcc*,
a, *b*, *c*,
aaab, *aaac*, *aabb*, *aabc*, *aacc*, *abbb*, *abbc*, *abcc*, *bbbc*, *bbcc*.

Here there are 4 of this form, *aaab*, and the number of changes is 4, } therefore $4\times4=16$
There are 3 of this form, *aabb*, and the changes are 6, } $3\times6=18$
And there are 3 of this form, *aabc*, and the changes are 12, } $3\times12=36$
Number of changes required 70

Problem V. To find the number of combinations of any given number of things, all different from one another, and taken any given number at a time.

Rule. Let m denote the number of things, and n denote the number taken at a time.

Then $\frac{m\times\overline{m-1}\times\overline{m-2}\times\overline{m-3}\times\overline{m-4},\ \&c.\ \text{to } n \text{ terms}}{1\times2\times3\times4\times5,\ \&c.\ \text{to } n \text{ terms.}}$ = to the Anſw.

Example. How many combinations can be made with three letters of the alphabet, reckoning but 24 letters in the alphabet?

Here $\frac{24\times\overline{24-1}\times\overline{24-2}}{1\times2\times3} = 6\times23\times22 = 2024$, the Anſwer.

Cor. I. The number of Combinations of *n* things, taken out of *m*, is equal to the co-efficient of the $\overline{n+1}$*th* term of a binomial, raiſed to the *mth* power.

Cor. II. The number of all the poſſible Combinations of all the one's, two's, three's, &c. is one leſs than the ſum of all the co-efficients of a binomial raiſed to the m^{th} power, and that is equal to 2^m-1. This is the number of all the elections.

Cor. III. There is the ſame number of combinations of *n* things out of *m*, as of *m*—*n* things out of *m*.

Cor. IV. There is but one Combination of *m* things out of *m*, whether they be all different, or ſeveral of one or more ſorts.

Cor. V. The number of Permutations of *m* things, taken *n* at a time, is equal to the like number of Combinations multiplied into *n* terms of the natural ſeries, 1, 2, 3, 4, 5, &c.

Problem VI. To find the number of combinations of any number of things, in which there are certain quantities of different ſorts, and in the combinations of which ſuppoſing any number to be taken at a time.

Here, when the quantity is often repeated, as *aaa*, *bbbb*, &c. they may be written thus a^3, b^4, &c. where the index ſhews the number of repetitions of any quantity, or how often it is to be taken, then proceed as follows:

Place the number of things ſo that the greateſt indices may be firſt, and the reſt decreaſe in order. Then begin at the firſt letter, and join it with the ſecond, third, fourth, &c. to the laſt; alſo, take the ſecond letter and join it to the third, fourth, &c. and likewiſe the third, and proceed in the ſame way; and then the fourth, fifth, &c. till all be done; always taking care to reject ſuch combinations as you had before. Thus you have the combination of all the two's.

Then, for all the three's, join the firſt letter of every one of the two's ſucceſſively; and then the ſecond and third, &c. to the laſt, leaving out ſuch combinations as are had before. So you will have the combinations of the three's.

Proceed the ſame way to get the combinations of all the four's, five's, &c. till you come at the given number to be taken at a time, and ſo you will at laſt get all the ſeveral forms of combination, and how many there are of each ſort.

But, when there are many terms, it will be proper to proceed in this manner: let the ſeveral ſorts of things denoted be *a*, *b*, *c*, *d*, &c. and their number be *m*, and let the quantity to be taken at a time be *n*; alſo, let *p*, *q*, *r*, *s*, &c. be the reſpective numbers of each ſort; ſo will a^p, b^q, c^r, d^s, &c. denote the repetitions of the ſeveral different ſorts of things, whether equal or unequal.

Likewiſe, let a^t, b^v, c^w, d^x, &c. be the form to be combined, the indices being *t*, *v*, *w*, *x*, &c. either equal or unequal; then the Rule for any Single Form will be as under.

Let A, B, C, D, &c. be the number of different letters in the *m* things expoſed, the indices of which are equal to or greater than (*t*, *v*, *w*, *x*, &c. reſpectively) the indices in the *n* things. Then the number of combinations in that form, is $\frac{A\times\overline{B-1}\times\overline{C-2}\times\overline{D-3}\,\&c}{R\,S,\ \&c.}$ continued to as many terms as there are different letters in the form propoſed; where $R = 1\times2$, or $1\times2\times3$, or $1\times2\times3\times4$, &c. when any index in the form is twice, thrice, or four times, &c. repeated; and the like for S, &c.

The operation muſt be repeated for every form, and the ſum of all will give the number of combinations required.

Cor. Hence, before the required number of combinations can be determined, all the different forms of combination muſt be firſt found; the beſt method for which is this:

Set down all the indices contained in the *m* quantities, taking the greateſt firſt, and the reſt in like order. Then, to get all the forms, write down the greateſt index firſt, and the next leſs, towards the right hand; and ſo on, till the ſum be equal to *n*; obſerving that the number of places cannot exceed the number of different letters.

Proceed from row to row, in breaking the leaſt figures, viz. thoſe towards the right hand, into others that are ſtill leſs, till they be units. And thus go on, figure by figure, from right to left, till the numbers are diminiſhed as low as the caſe will admit.

Example. How many combinations are there in a^4, b^2, c^2, d, e, taking 8 at a time?

Here the indices of the given quantity, are 42211; $n = 8$, and the number of places, in any form, cannot exceed 5.

	Forms.	Combinations.
	422	1
	4211	6
	41111	1
	3221	2
	32111	2
	22211	1
Total		13 the Anſw.

Here the method of deriving the forms in this Example, is ſo obvious, that it is needleſs to ſay any thing about it; but it may be neceſſary to explain the application of the preceding Rule, in finding the number of combinations according to each form.

The firſt form is 422. Now there is but one index in the given quantity that contains the firſt index of this form (4); therefore, $A = 1$; but there are three indices that contain the ſecond and third indices of this form; and therefore, $B = 3$, and $C = 3$; alſo, ſince in the ſaid form there is one index, (namely 2) that occurs twice, therefore, $R = 1\times2 = 2$.

Hence, by the Rule, the number of combinations $= \frac{1\times2\times1}{2} = 1$; in the ſecond form, $A = 1$, $B = 3$, $C = 5$, and $D = 5$; alſo one index (viz. 1) occurs twice; therefore, $R = 1\times2 = 2$.

Hence the number of combinations $\frac{1\times2\times3\times2}{2} = 6$.

In the third form, $A = 1$, $B = 5$, and $C = 5$, $D = 5$; and $E = 5$; and one index (viz. 1) occurs four times; therefore, $1\times2\times3\times4 = 24 = R$; and the number of combinations $= \frac{1\times4\times3\times2\times1}{24} = 1$.

In the fourth form, $A = 1$, $B = 3$, and $C = 3$, $D = 5$; and $R = 2$; conſequently the number of combinations $= \frac{1\times2\times1\times2}{2} = 2$.

In the fifth form, $A = 1$, $B = 3$, $C = 5$, $D = 5$, and $E = 5$; and $R = 1\times2\times3 = 6$; therefore, the number of combinations $= \frac{1\times2\times3\times2\times1}{6} = 2$.

In the laſt form, $A = 3$, $B = 3$, $C = 3$, $D = 5$, and $E = 5$; and here one index, (viz. 2) occurs thrice, therefore, $R = 1\times2\times3 = 6$; and another index (viz. 1) occurs twice, therefore, $S = 1\times2 = 2$; and, conſequently, the number of combinations $= \frac{3\times2\times1\times2\times1}{6\times2} = 1$.

The ſum of all the combinations is 13, the Anſwer.

Problem VII. To find how many compoſitions of things, each conſiſting of any ſpecified number, can be taken out of the ſpecified number of rows, each containing any given number of things.

Rule. Involve the number of things in each row, to the power denoted by the number, that is, in each compoſition; or, which is the ſame, to the power denoted by the number, which expreſſes the quantity of rows, and the reſult will be the Anſwer.

Cor. If *n* be the number of rows, or number in each compoſition, and *m* = number of things in each row; then $\frac{m^{n+1}-m}{m-1}$, (or $\frac{m^n-1}{m-1}\times m$.) is equal to the number of compoſitions of all the one's, two's, three's, &c. to *n*.

Example I. How many combinations of three letters are there in three alphabets, each containing 24 letters?

Here $24^3 = 13824$, the Anſwer.

Example II. How many words can be formed out of the whole alphabet, ſuppoſing any compoſition from 2 to 24, to make a word.

Here $m = 24$, and $n = 24$; and by the above Corollory $\frac{24^{24}-1}{23}\times24 =$ the number of words, if the compoſitions of 1 were included. Now the compoſitions of $1 = 24$; and therefore $\frac{24^{24}-1}{23}\times24-24 = 1391724288887252999425128493402176$, the Anſwer required.

Other Problems of the like nature might be given; but they are ſuch, as are ſeldom wanted; and, indeed, more have been already introduced, than are to be met with in moſt books of Arithmetic.

ART. XXV. OF CIRCULATING DECIMALS.

Definitions.

I. A Circulating, or Recurring Decimal, is that wherein one or more figures are continually repeating; as 42.5876666, &c. which is named a Single Circulate; and 285,264264264, &c. which is called a Compound Circulate.

II. The recurring part of a Decimal, is named the Repetend.

III. A Single Repetend, is expreſſed by writing a point over the circulating figure, thus .2333, &c. is denoted by $.2\dot{3}$.

IV. A Compound Repetend, is diſtinguiſhed by putting points over the firſt and laſt repeating figures; thus .375375375, &c. is expreſſed $.\dot{3}7\dot{5}$.

V. Similar Circulating Decimals, are ſuch as conſiſt of the ſame number of figures, and begin at the ſame place, either before or after the Decimal point; thus $.\dot{3}$ and $.\dot{4}$ are Similar Circulates; ſo alſo are $\dot{3}.4\dot{2}$ and $\dot{5}.2\dot{7}$, &c.

VI. Diſſimilar Repetends, conſiſt of an unequal number of figures, and begin at different places.

VII. Similar and conterminous Circulates, are ſuch as begin and end at the ſame place; as $2.4\dot{6}3\dot{8}$, $5.3\dot{2}4\dot{6}$, and 7.5435, &c.

N. B. Any Proper Vulgar Fraction, whoſe denominator is compounded of any other number than 2 and 5, will produce a Circulating Decimal; which will always repeat before there are as many figures obtained, as there are units in the denominator.

Theorem. In any Circulating Decimal, the whole circulating or repeating part, running on for ever, is equal to a Vulgar Fraction, whoſe numerator is the number repeating (or repetend) and the denominator as many 9's as there are figures in the repetend.

Cor. I. The circulation may be ſuppoſed to begin at any figure of the repetend.

Cor. II. If any circulating number be multiplied by any given number, the product will be a circulating number, and the repetend will conſiſt of the ſame number of figures as before.

Cor. III. If a circulating decimal has a repetend of any number of figures, it may be conſidered as having a repetend of twice, thrice, or any multiple of that number. Thus $4\dot{1}3\dot{7}$, is equivalent to $4.\dot{1}373\dot{7}$, or $4.\dot{1}37373\dot{7}$, &c.

Cor. IV. If two or more numbers be added together that have repetends of equal places, the ſum will have a repetend of the ſame number of places.

Prob. I. Having a vulgar fraction given in the loweſt terms, and the denominator a prime, (but neither 2 nor 5) to find the number of figures that circulate in the decimal thereof.

Rule. Divide 99999, &c. by the denominator till 0 remains; then the number of 9's, made uſe of, will be equal to the number of places in the repetend.

Example. Let the fraction be $\frac{2}{7}$,

Then $\frac{7)999999,\ \&c.}{142857,\ \text{and 0 remains}}$

So, in taking 6 nines, there is no remainder; and conſequently if the fraction $\frac{2}{7}$ be reduced to a decimal, it will have a repetend of ſix places.

Prob. II. Having a vulgar fraction in the loweſt terms, and the denominator made up of two or more primes (2 and 5 excluded) to find the number of figures that circulate in the decimal thereof.

Rule. Find by the laſt Problem the number anſwering to each prime; alſo find by Prob. IV. of fractions, the leaſt dividend that will divide by each ſuch number without a remainder, and it will be equal to the number of figures in the repetend of the decimal.

Example. Let the fraction be $\frac{13}{11\times37}$, or $\frac{13}{407}$.

Here the repetend by 11, conſiſts of 2 places, and that by 37, of 3 places: alſo the leaſt number that will divide by 2 and 3 is 6. Conſequently the fraction $\frac{13}{407}$ will produce a repetend of 6 places.

Problem III. Having given any number of diſſimilar repetends, to reduce them to ſimilar and conterminous ones.

Rule. Find the leaſt dividend that will divide by the ſeveral figures, denoting the number of places in the propoſed repetends. Then that dividend will denote the number of places in each ſimilar and conterminous repetend; then that number, whoſe repetend begins the farthermoſt to the right hand, (viz. at the greateſt diſtance from the units figure) muſt be increaſed till the repetend conſiſt of the due number of figures, as above mentioned; and then the decimals in the reſt of the numbers muſt be augmented, if need be, ſo as to have a like number in each.

Example. Let the diſſimilar repetend be $6.\dot{2}1\dot{4}$, $.\dot{1}\dot{5}$, and $1.\dot{2}$.

Here the number of places in the firſt repetend is 3; in the ſecond 2; and in the third 1; and the leaſt number that will divide by each of theſe is 6.

Therefore there muſt be ſix places in the repetend, and conſequently the numbers will become $6.\dot{2}1421\dot{4}$; $.\dot{1}5151\dot{5}$; and $1.\dot{2}2222\dot{2}$, reſpectively; and thus they are made ſimilar and conterminous. The nature of this proceſs is farther evident from what has been ſaid in Corollories I. and III. of the preceding Theorem.

Note. If a number be propoſed that is not a repetend of itſelf, yet one or more cyphers (as decimals) may be annexed, and ſo it may be conſidered as having a repetend of cyphers.

Problem IV. To add circulating decimals together.

Rule. Make the repetends ſimilar and conterminous, if they are not ſo already; find the ſum of the ſimilar repetends, and divide the ſame by a number, conſiſting of as many nines as is the common number of places in the ſimilar repetends; then the remainder will be the repetend of the required ſum; and the quotient will be the number to be carried to the next column to be added as finite decimals.

Example. Let it be required to add $2.\dot{5}$; $62.\dot{3}4\dot{2}$; and $.\dot{3}2\dot{7}$ together.

$$\begin{array}{r} 2.\dot{5}5555\dot{5} \\ 62.\dot{3}4234\dot{2}3 \\ .\dot{3}27327\dot{3} \\ \hline 65.2\dot{2}5225\dot{2} \\ \hline \end{array}$$

Here, the numbers being made ſimilar, and placed in order for addition, will ſtand as they are here put down; and the ſum of the repetends is 1252251, which divided by 999999, the quotient is 1, to be carried to the next row, and the remainder is 252252, to be put down for the repetend; and ſo the whole ſum is $65.2\dot{2}5225\dot{2}$, but it is obvious that this repetend may be taken in fewer figures; thus the above ſum is $= 65.\dot{2}2\dot{5} = 65.\dot{2}\dot{2}$.

Problem V. To ſubtract circulating decimals.

Rule. Make the repetends ſimilar and counterminous, and ſubtract as in finite decimals; obſerving to make the laſt figure in the remainder 1 leſs, when the repetend in the number ſubtracted is greater than the repetend in the number ſubtracted from.

Example. From $35.\dot{1}\dot{2}$ take 2.764.

Here the numbers reduced to a like repetend, are $35.12\dot{1}\dot{2}$, and $2.76\dot{4}\dot{4}$. And $35.12\dot{1}\dot{2} - 2.76\dot{4}\dot{4} = 32.3568$. But the repetend in the number ſubtracted (viz. $\dot{4}\dot{4}$) being greater than the other (viz. $\dot{1}\dot{2}$) therefore I take 1 from the laſt decimal figure, and ſo the proper remainder is $32.35\dot{6}\dot{7}$; the two laſt figures being a repetend.

Problem VI. To multiply or divide circulating decimals.

Rule. By the foregoing Theorem, turn both the terms into their equivalent vulgar fractions, and find the product or quotient of theſe fractions as uſual. Then, if the Anſwer is required in decimals, reduce the fractional product, or quotient, to a decimal.

Exampe I. Multiply $4.7\dot{2}$ by $3.\dot{6}$

Here $4.72 = 4.7\frac{2}{9} = \frac{42.5}{9} = \frac{425}{90}$; and $3.\dot{6} = 3\frac{6}{9} = 3\frac{2}{3} = \frac{11}{3}$.

Then, $\frac{425}{90}\times\frac{11}{3} = \frac{425\times11}{90\times3} = \frac{185\times11}{18\times3} = \frac{935}{54} = 17.\frac{17}{54} = 17.3\dot{1}4\dot{8}$.

Example II. Divide $3.\dot{5}$ by $.\dot{2}\dot{4}$.

Here $3.\dot{5} = 3.\frac{5}{9} = \frac{32}{9}$; and $.\dot{2}\dot{4} = \frac{24}{99}$. And $\frac{32}{9} \div \frac{24}{99} = \frac{32}{9}\times\frac{99}{24} = \frac{32\times99}{9\times24} = \frac{4\times11}{3} = \frac{44}{3} = 14.666,\ \&c. = 14.\dot{6}$.

ART. XXVI. OF PERFECT NUMBERS.

Definition.

A perfect number is one that is equal to the ſum of all its aliquot parts.

Theorem. If any number of terms of the following geometric progreſſion, 1, 2, 4, 8, 16, &c. be taken, and if the ſum be a prime number, then ſuch ſum, multiplied by the laſt term, will give a perfect number.

Thus the ſum of the two firſt terms $1+2=3$, a prime, and $2\times3=6$, a perfect number; for its aliquot parts are 3, 2 and 1, which make 6; and therefore 6, is a perfect number.

If three terms of the ſeries are taken $1+2+4=7$, a prime; and $4\times7=28$, a perfect number.

Alſo $1+2+4+8+16=31$, a prime; and $31+16=496$, a perfect number.

Likewiſe $1+2+4+8+16+32+64=127$, a prime; and $127\times64=8128$, a perfect number.

Again, if 13 terms of the ſeries be taken, the ſum will be 8191, a prime; which multiplied by the laſt term, (4096) gives 33550336, a perfect number.

This method will always find a perfect number; and, I believe, every perfect number, though that has not yet been demonſtrated; nor has it been demonſtrated what number of terms of the given ſeries muſt be taken each time that the ſum may be a prime; ſo that the finding whether the ſum be a prime or not, in large numbers is exceeding tedious, and renders the proceſs very intricate.

There are but few perfect numbers yet diſcovered; and Dr. Harris, in his Lexicon Technicum, ſays, there are but 10 ſuch numbers between 1, and 1 million of millions.

A SUPPLEMENT TO ARTICLE XII.

The following Rule for extracting the Cube Root, is derived from the ſame principles as the laſt in Art. XII. but it will be ſtill more commodious for practice.

Rule. Take $\frac{1}{3}$ of the difference between the number to be extracted, and the neareſt Cube: alſo take the *ſum of*, or *difference between*, the number to be extracted, and the ſaid third part, according as ſuch Cube is *leſs*, or *greater*, than the given number, and divide the reſult by the aforeſaid Cube; then the ſquare Root of the quotient, added to the aſſumed Root, will be equal to twice the required Root, *nearly*.

If more accuracy is requiſite, the operation muſt be repeated.

Generally, If any number to be extracted be denoted by N, the index of the power by *n*, and an aſſumed Root, taken at pleaſure (but as near as may be to the true one) by *r*, then will

$$\frac{1}{n-1}\times\sqrt{\frac{N \overset{+}{\backsim} \frac{n-2}{n}\overline{N \backsim r^n}}{r^{n-2}}} + \overline{n-2}.r,$$

be equal to the required Root, *nearly*.

N. B. When the aſſumed Root (r) is too ſmall, then $\frac{n-2}{n}\overline{N \backsim r^n}$ muſt be *added*, to N; but when *r*, is too great, then the *difference* between this quantity and N muſt be taken. This approximation, commonly *trebles* the number of true figures in the Root at each operation.

The above *general method* I inveſtigated after the Copy of this Syſtem went to the preſs. It appears inferior to none for eaſe and expedition; and, I believe, I need not ſcruple to aſſert, that it is *intirely new*.

I have nothing more to add under this Syſtem. And indeed (excepting duodecimal arithmetic or croſs multiplication, which will be introduced when we come to Mensuration*) I have ſo exhauſted the ſubject, that there ſcarce remains any thing that I could have farther inſiſted on; the conſideration of which, together with that correctneſs, and mathematical order, which, I truſt, is conſpicuous through the whole, gives me the moſt ſanguine hopes that it will completely anſwer the deſire of every Subſcriber.*

EXCISE OFFICE, BROAD STREET. *ROBERT MOODY.*

ARITHMETICAL, in a general ſenſe, implies any thing partaking of the nature of Arithmetic, whether whole or broken numbers, or analogical calculation.

ARITHOMANCY, ſignifies a ſpecies divination performed by numbers, which were written down at random by ſeveral perſons on various ſlips of paper, or parchment, for the uſe of the conjuror to impoſe on the underſtandings of weak credulous people.

ARISTOXENIANS, in the peripatetic ſcience, ſignify the diſciples of Ariſtoxenes of Tarentum, a ſcholar of Ariſtotle, who were diametrically oppoſite in their principles to the Pythagoreans, with regard to the meaſure of ſounds in muſic, and its intervals; as the former had recourſe to the ear, whilſt the latter laid claim to mathematical calculations to aſcertain their doctrine.

ARK, or *Noah's* Ark, in holy writ, ſignifies a floating veſſel built by Noah for the preſervation of his family and the ſeveral ſpecies of animals during the deluge.

The ark has afforded ſeveral points of curious inquiry among critics and naturaliſts, relating to its form, capacity, materials, &c.

By the deſcription Moſes gives of the ark, it appears to have been divided into three ſtories, each ten cubits or 15 feet high; and it is agreed on, as moſt probable, that the loweſt ſtory was for the beaſts, the middle for the food, and the upper for the birds, with Noah and his family; each ſtory being ſubdivided into different apartments, ſtalls, &c. Though Joſephus, Philo, and other commentators, add a kind of fourth ſtory under all the reſt; being, as it were, the hold of the veſſel, to contain the ballaſt and receive the filth and feces of ſo many animals: but F. Calmet thinks, that what is here reckoned a ſtory, was no more than what is called the keel of ſhips, and ſerved only for a conſervatory of freſh water.

Ark *of the Covenant*, in Scripture, denotes a ſmall cheſt or coffer, three feet nine inches in length, two feet three inches in breadth, and two feet three inches in height, in which were contained the golden pot that had manna, and Aaron's rod, and the tables of the covenant.

This coffer was made of ſhittim-wood, and covered with a lid, which was made of ſolid gold. The ark was repoſited in the holieſt place of the tabernacle. It was taken by the Philiſtines, and detained 20, ſome ſay 40, years, at Kirjath-jearim; but the people being afflicted with emerods on account of it, returned it with divers preſents. It was afterwards placed in the temple.

The lid or covering of the ark was called the propitiatory or mercy-ſeat; over which were two figures placed, called cherubims, with expanded wings of a peculiar form. Here the Schechinah reſted both in the tabernacle and temple in a viſible cloud: hence were iſſued the divine oracles by an audible voice; and the high prieſt appeared before this mercy-ſeat once every year on the great day of expiation; and the Jews, wherever they worſhipped, turned their faces towards the place where the ark ſtood.

In the ſecond temple there was alſo an ark, made of the ſame ſhape and dimenſions with the firſt, and put in the ſame place, but without any of its contents and peculiar honours. It was uſed as a repreſentative of the former on the day of expiation, and a repoſitory of the original copy of the holy Scriptures, collected by Ezra, and the men of the great ſynagogue, after the captivity.

And in imitation of this, the Jews to this day have a kind of ark in their ſynagogues, wherein their ſacred books are repoſited. This they call aron. Leo of Modena gives a deſcription thereof in his account of the cuſtoms and ceremodies of thoſe of his nation. "The Jews (ſays he), in the eaſtern ſide of their ſyuagogues, have an ark, or armory, called aron, in memory of the ark of the covenant. In this are preſerved the five books of Moſes."

A cheſt or coffer, very nearly reſembling the Jewiſh ark, and called the houſe of the god, was found in Huaheine, one of the iſlands in the ſouthern ſea. Sir Joſeph Banks could obtain no other information concerning it than what the name imports. Hawkeſworth's Account, &c. Vol. ii. p. 252.

ARM, in anatomy, implies a part of the human body, terminating at one end in the ſhoulder, and at the other in the hand.

Arm, in geography, ſignifies a branch of a ſea or river. Italy and Sicily are only parted by an arm of the ſea. St. George's arm in the Mediterranean is the Thracian Boſphorus.

Arm is alſo uſed figuratively for power. The ſecular arm is the lay or temporal authority of a ſecular judge; to which recourſe is had for the execution of the ſentences paſſed by eccleſiaſtical judges.

The church ſheds no blood: even the judges of inquiſition, after they have found the perſon guilty, ſurrender him to the ſecular arm.

The council of Antioch, held in 341, decrees, that recourſe be had to the ſecular arm to repreſs thoſe who refuſe obedience to the church: for ſecular arm, they here uſe exterior power.

ARMADA, a Spaniſh term, ſignifying a fleet of men of war. The armada which attempted to invade England in the time of Queen Elizabeth, is famous in hiſtory. It was in part diſperſed by the winds, and the reſidue ſubdued by the Engliſh fleet.

This armada, to which the Spaniards, in confidence of ſucceſs, gave the name of Invincible, conſiſted of 150 ſhips, moſt of which were greatly ſuperior in ſtrength and ſize to any that had been ſeen before. It had on board near 20,000 ſoldiers and 8000 ſailors, beſides 2000 volunteers of the moſt diſtinguiſhed families in Spain. It carried 2650 great guns, was victualled for half a year, and contained ſnch a quantity of military ſtores, as only the Spaniſh monarch, enriched by the treaſures of the Indies and America, could ſupply. After this total defeat there was a medal ſtruck on the occaſion with this motto, "Afflavit Deus, et diſſipantur."

ARMADARE, to give arms, in an heraldic phraſe, implies the giving title to, or dubbing of a knight: hence the king is ſaid to arm his ſubjects with honours; i. e. beſtowing on them titles that require a regiſtry in the office of arms, as family achievements.

ARMADILLA, in Spaniſh America, denotes a ſquadron of men of war, to the number of ſix or eight, from twenty-four to fifty pieces of cannon, which the king maintains, to prevent foreigners from trading with the Spaniards and the Indians, both in time of peace, and war.

The veſſels of this armadilla are thoſe that have been ſo much talked of, under the name of guarda coſtas. They have even power to take all Spaniſh merchant-ſhips they meet with on the coaſts that have not licences from the king.

The South ſea has its armadilla as well as the North ſea. The ordinary abode of the former are at Calao, a port of Lima; that of the latter at Carthagena.

ARMADILLO, in zoology, is a ſynonyme of the daſypus.

ARMAMENT, in military or ſea language, implies a large body of forces, raiſed and provided with the furniture of war, either for land or ſea ſervice.

ARMAMOLUTA, in law, implies acts performed with ſharp or dangerous weapons: hence, the puniſhment of fine and impriſonment for carrying concealed armamoluta.

ARMAMUTARE, or exchange of arms, was anciently a ceremony uſed to confirm a league of friendſhip between European powers; which is ſtill retained by the Northern States, and is always practiſed with rigid ceremony by the grand ſeignor, and all potentates of the Mahometan perſuaſion.

ARMAREVERSATA, inverted arms, was a puniſhment enforced by law when a man was convicted of treaſon or felony.

ARMATURA, or Armature, in a general ſenſe, is the ſame with what we otherwiſe call armour.

Armatura is more particularly uſed in the ancient military art, for a kind of exerciſe, performed with miſſive weapons, ſuch as darts, ſpears, arrows, and the like. In this ſenſe, armatura ſtands contradiſtinguiſhed from palaria; the latter being the exerciſe of the heavy-armed, the former of the light-armed.

The armatura was practiſed with great diligence among the Romans: they had their campidoctores, on purpoſe to inſtruct the tyrones or young ſoldiers in it. Under it were included the throwing of the ſpear or javelin, ſhooting with bows and arrows, &c.

ARMED, in heraldry, is uſed when the horns, feet, beak, or talons, of any beaſt or bird of prey, are of a different colour from the reſt of the body.

Armed *Ship*, is a veſſel occaſionally taken into the ſervice of government in time of war, and employed to guard ſome particular coaſt, or attend on a fleet. It is armed and equipped in all reſpects like a ſhip of war, commanded by an officer of the navy, who has the rank of maſter and commander. All ſhips of this ſort are upon the eſtabliſhment of the king's ſloops, having a lieutenant, maſter, purſer, ſurgeon, &c.

ARMENA, in botany, a ſpecies of wild aſparagus; alſo a ſynonyme of many eſculent plants, particularly young cabbages or greens in the ſprout.

ARMENIACA, in botany, is a ſynonyme of the apricot or prunus.

ARMENIANS, in eccleſiaſtical hiſtory, denote the Chriſtians who reſide in the country of Armenia, who are partly of the Greek church, having no communion with the Romiſh religion; but are governed by patriarchs and epiſcopacy peculiar to themſelves.

The Armenians are an honeſt, civil, polite people, ſcarce troubling themſelves about any thing elſe but trade, which they carry on in moſt parts of the world, by which means they have ſpread themſelves over the eaſt, and alſo great part of Europe; and wherever they come, commerce is carried on with ſpirit and advantage.

The religion of the Armenians is the Chriſtian, of the Eutychian ſect: that is, they own but one nature in Jeſus Chriſt; and when they ſpeak of the hypoſtatical union, that he is perfect God and perfect man without mixture.

The Armenian clergy conſiſt of patriarchs, archbiſhops, doctors, ſeculiar prieſts, and monks. The ſeculiar prieſts are not allowed to marry a ſecond time; and therefore they take care to chooſe young healthy wives: they maintain themſelves and families by following ſome occupation, inſomuch that they have hardly time to perform their eccleſiaſtical functions: they lie in the churches on the vigils of thoſe days they are obliged to officiate.

The Armenian monks are of the order of St. Baſil; and every Wedneſday and Friday they eat neither fiſh, nor eggs, nor oil, nor any thing made of milk; and during Lent they live upon nothing but roots: they are allowed wine only on the Saturday in the Holy Week, and meat on the Eaſter Sunday. Beſides the great Lent, they have four others of eight days each, which are inſtituted to prepare for the four great feſtivals of the Nativity, the Aſcenſion, the Annunciation, and of St. George; in which times they muſt not ſo much as ſpeak of eggs, fiſh, oil, or butter.

The Armenians have ſeven ſacraments: baptiſm, confirmation, penance, the euchariſt, extreme unction, orders, and matrimony. In baptiſm, the child is plunged three times into the water, and the ſame form of words that is uſed with us is repeated every time; the prieſt then puts a ſmall cord made with ſilk and cotton on the neck of the infant, and anoints his forehead, chin, ſtomach, arm-pits, hands, and feet, making the ſign of the croſs on each part. When the child is baptized, he is carried home by the godfather with the ſound of drums and trumpets. The women do not go to church till forty days after their delivery; and they obſerve many Jewiſh cuſtoms.

At the communion, to which infants of two or three months old are admitted, the prieſts give a piece of the conſecrated hoſt ſoaked in the conſecrated wine. The elements are covered with a great veil, and placed in a cup-board near the altar, on the ſide of the goſpels. When the prieſt takes the chalice and pattin, he is followed by his deacons and ſubdeacons, with flambeaux and plates of copper furniſhed with bells: in this manner, with a cenſer before him, he goes in proceſſion round the ſanctuary: he then ſets them on the altar, pronounces the words of conſecration, and turns himſelf to the people, who fall down, kiſs the earth, and beat their breaſts: then, after taking it himſelf, he diſtributes the hoſt ſoaked in wine to the people.

The Armenians ſeem to place the chief part of their religion in faſtings and abſtinences: and among the clergy, the higher the degree the lower they muſt live; inſomuch that it is ſaid the archbiſhops live on nothing but pulſe. They conſecrate holy water but once a-year; at which time every one fills a pot and carries it home, which brings in a conſiderable revenue to the church.

ARMENUS Lapis, Armenian ſtone, in natural hiſtory, denotes a mineral ſubſtance, improperly called a ſtone; being only an ocherous earth, and properly called blue ochre.

It was in ſo high eſteem as a paint among the ancients, that counterfeits were continually attempted to ſerve in its place.

It is of an even regular texture; and of a fine blue, and frequently mixed with green. It is ſoft, tender, and light; of an even, but ſomewhat duſty, ſurface; it adheres firmly to the tongue, and is dry, but not harſh to the touch. It eaſily breaks between the figures, and does not ſtain the hands.

It is of a brackiſh taſte, dut does not ferment with acids. It is a ſcarce foſſil, found very pure, though in ſmall quantities, in the mines at Goſſelaer in Saxony.

It is frequently found ſpotted with green, and ſometimes with black; and very often is mixed among the green ochre, called berggruen by the Germans, which has thence been erroneouſly called by its name.

ARMIGER, ſignifies a title of dignity, belonging to ſuch gentlemen as bear arms: and theſe are either by curteſy, as ſons of noblemen, eldeſt ſons of knights, &c.; or by creation, ſuch as the king's ſervants, &c.

ARMILAUSA, implies a ſhort jacket, or coat worn anciently by the archers and others in a military department. Hence the Armilauſians or Archers.

ARMILLA Membranosa, or Membrosa, in anatomy, ſignifies the circular ligament which comprehends all the tendons belonging to the whole band within a circle, in the region of the carpus.

ARMILLARY, in a general ſenſe, ſomething conſiſting of rigns or circles.

Armillary *Sphere*, is an artificial ſphere compoſed of a number of circles of the mundane ſphere, put together in their natural order, to eaſe and aſſiſt the imagination in conceiving the conſtitution of the heavens, and the motions of the celeſtial bodies. The armillary ſphere revolves upon its axis within a ſilvered horizon, which is divided into degrees, and moveable every way upon a braſs ſupporter. The other parts are the equinoctial, zodiac, meridian, the two tropics and the two polar circles.

Armillary Trigonometer, in mechanics, implies an inſtrument ſo contrived as to facilitate operations in aſtronomy, dialling, and trigonometry.

ARMILLATI Milites, in hiſtory, ancient and modern, comprehend all thoſe who wear a badge in commemoration of ſome exploit performed for the good of their country, and in token of which, ſuch conſpicuous mark is given by the ſovereign, but if ſuch badges of honour was only to the reward of real merit, the noble and honourable orders in theſe realms would have but few knights companions to wear ſtars, garters, or collars.

ARMINIANS, in eccleſiaſtical hiſtory, imply a religious ſect, which aroſe in Holland, by a ſeparation from the Calvaniſts; their apoſtle Armenius began his ſchiſm in the Dutch eſtabliſhed church by thinking the doctrine of Calvin, with regard to free-will, predeſtination, and grace, too ſevere, expreſſed his doubts concerning them in the year 1591; and upon farther inquiry adopted ſentiments more nearly reſembling thoſe of the Lutherans than of the Calviniſts.

The diſtinguiſhing tenets of the Arminians may be compriſed in the following five articles; relating to predeſtination, univerſal redemption, the corruption of man, converſion and perſerverance.

1. Predeſtination they maintain, "That God, from all eternity, determined to beſtow ſalvation on thoſe whom he foreſaw would perſevere unto the end in their faith in Chriſt Jeſus; and to inflict everlaſting puniſhments on thoſe who ſhould continue in their unbelief, and reſiſt, unto the end, his divine ſuccours; ſo that election was conditional, and reprobation in like manner the reſult of foreſeen infidelity and continued wickedneſs."

2. Univerſal redemption they maintain, "That Jeſus Chriſt, by his ſufferings and death, made an atonement for the ſins of all mankind in general, and of every individual in particular; that, however, none but thoſe who believe in him can be partakers of their divine benefit."

3. On the third article, they held, "That true faith cannot proceed from the exerciſe of our natural faculties and powers, nor from the force and operation of free will; ſince man, in conſequence of his natural corruption, is incapable either of thinking or doing any good thing; and that therefere it is neceſſary, in order to his converſion and ſalvation, that he be regenerated and renewed by the operation of the Holy Ghoſt, which is the gift of God through Jeſus Chriſt."

4. Converſion they maintain, "That this divine grace, or energy of the Holy Ghoſt, begins and perfects every thing that can be called good in man, and conſequenty all good works are to be attributed to God alone; that, nevertheleſs, this grace is offered to all, and does not force men to act againſt their inclination, but may be reſiſted and rendered ineffectual by the perverſe will of the impenitent ſinner." Some modern Arminians interpret this and the laſt article with a greater latitude.

5. Perſeverance they maintain, "That God gives to the truly faithful, who are regenerated by his grace, the means of preſerving themſelves in this ſtate;" and though the firſt Arminians made ſome doubt with reſpect to the cloſing part of this article, their followers uniformly maintain, "that the regenerate may loſe true juſtifying faith, forfeit their ſtate of grace, and die in their ſins."

The modern ſyſtem of Arminianiſm likewiſe, founded on a comprehenſive plan projected by Arminius himſelf, as appears from a paſſage in his laſt will, extends the limits of the Chriſtian church, and relaxes the bonds of fraternal communion in ſuch a manner, that Chriſtians of all ſects and denominations, whatever their ſentiments and opinions may be, papiſts excepted, may be formed into one religious body, and live together in brotherly love and concord. But, in order to avoid the reproach of being altogether unconnected by any common principles, Epiſcopius drew up a confeſſion of faith, expreſſed for the moſt part in words and phraſes of Holy Scripture, which the Arminians have generally adopted, though not enjoined upon them by any authoritative obligation. The Arminians are alſo called Remonſtrants, from an humble petition intitled their Remonſtrance, which, in the year 1610, they addreſſed to the Sates of Holland. The principal writers are, Arminius, Epiſcopius, Vorſtius, Grotius, Curcellæus, Limborch, Le Clerc, and Wetſtein.

ARMISTICE, in military affairs, implies a temporary truce or ceſſation of arms for a ſhort time. The word is Latin, *armiſtitium*; and compounded of *arma*, "arms," and *ſto*, "to ſtand, or ſtop."

ARMOISIN, a ſilk ſtuff, or kind of taffety, manufactured in the Eaſt Indies, at Lyons in France, and at Lucca, in Italy. That of the Indies is ſlighter, than thoſe made in Europe.

ARMONIAC, the ſame as Ammoniac.

ARMONICA, the ſame as Harmonica.

ARMORIAL, in an heraldic phraſe, implies ſomething relating to coats of arms.

ARMORACIA, in botany, is a ſynonymous term for the eſculent plant, the ſimple rhadiſh, which was uſed as the table vegetables of the ancients, who uſe them as the moderns do that of cabbage.

ARMORIC, in Galic antiquities, implies thoſe remains of time which have been collected in Brittany. Hence, the language of the provincials, is called the Armoric or Bas-breton; which ſeems to partake of the Welch, Iriſh and Erſe.

ARMORIST, in heraldry, ſignifies a perſon ſkilled in the knowledge of armory.

ARMORUM Concussio, in ancient hiſtory, denotes the claſhing of armour, practiſed by the Roman armies previous to an engagement, and intended to ſtrike terror in their enemies: it always followed the Claſſicum and the Barritus.

ARMOUR, in war, implies a defenſive habit, to ſecure the body from the attacks of an enemy. In ancient ſtatues, it is frequently called *harneſs*. Parts of armour are, the buckler, curiaſs, helmet, coat of mail, gantlet, &c.

A complete coat of armour, anciently conſiſted of a caſque or helm, a gorget, cuiraſs, gantlets, taſſes, braſſets, cuiſhes and covers for the legs, to which the ſpurs were faſtened. This they called *armour cap-a-pie*; and was the wear of the cavaliers and men at arms. The infantry had only part of it; viz. a pot or head-piece, a cuiraſs, and taſſes; but very light.

The horſes had alſo their armour, to cover the head and neck. Of all this furniture of war, ſcarce any thing is now retained except the cuiraſs; the gorget or neck-piece, worn by officers, being at preſent only a badge of honour, and of no defence.

Armour *of Coat*, is the eſcutcheon of any perſon, or family, with its ſeveral charges, and other furniture; as mantling, creſt, ſupporters, mottos, &c.

ARMOURER, a maker of arms, or armour. The Roman armourers were diſpoſed in certain places in the empire, it being forbid either to ſell, or buy, or make arms elſewhere. They were exempt from all offices and taxes, and received a ſalary from the public.

When once they had taken the employment on themſelves, neither they, nor their children, were allowed to quit it.

Armourer *of a Ship*, ſignifies a perſon whoſe office is to take care that the arms be in a condition fit for ſervice.

ARMOURY, is a ſtore-houſe of arms, or military habiliments, ſo as to be ready for uſe. There are armouries in the tower, and alſo in all arſenals, citadels, caſtles, &c.

Armoury is likewiſe uſed as a branch of heraldry; being the knowledge of coat-armours, as to their blazonry, and various intendments.

ARMS, *Arma*, in a general ſenſe, includes all kinds of weapons, whether for defence or offence.

It is ſuppoſed that the firſt artificial arms were of wood, and were only employed againſt beaſts; and that Belus, the ſon of Nimrod, was the firſt that waged war: whence, according to ſome, came the appellation bellum. Diodorus Siculus takes Belus to be the ſame with Mars, who firſt trained ſoldiers up to battle. Arms of ſtone, and even of braſs, appear to have been uſed before they came to iron and ſteel.

Joſephus aſſures us, that the patriarch Joſeph firſt taught the uſe of iron arms in Egypt, arming the troops of Pharoah with a caſque and buckler.

What contributed moſt to render the Romans, maſters of the world, was, that having ſucceſſively warred againſt all nations, they conſtantly renounced their own methods, arms, &c. whenever they met with better. Thus Romulus, during his war with the Sabins, a bold and warlike nation, adopted their broad buckler in lieu of the ſmall Argian buckler, which he had uſed till that time.

The principal arms of the ancient Britons were hatchets, ſcythes, lances, ſwords, and bucklers: the Saxons, &c. brought in the halbard, bow, arrows, arbalets, &c. It was enacted by the ancient laws of England, that every man was obliged to bear arms, except the judges and clergy.

Under Henry VIII. it was expreſsly enjoined on all perſons to be regularly inſtructed, in the exerciſe of the arms then in uſe; viz. the long bow and arrows; and to be provided with a certain number of them. Vide 33 H. VIII.

Arms, *Arma*, in law, are extended to any thing which a man takes in his hand in his wrath, to caſt at, or ſtrike another.

Arms of offence in uſe among us at preſent are, the ſword, piſtol, muſket, bayonet, pike, &c.

The arms of the Highlanders are, the broad ſword, target, poinard, and whinyar or durk, &c. There are ſeveral acts of parliament for diſarming the Highlanders; ſee 1 Geo. I. c. 54; 11 Geo. I. c. 26; 19 Geo. II. c. 39; 21 Geo. II. c. 34; 26 Geo. II. c. 22. and 29.

Fire **Arms** are thoſe charged with powder and ball: ſuch are cannon, mortars, and other ordinance; muſkets, carabines, piſtols, and even bombs, granadoes, carcaſſes, &c. In the Hiſtory of the Royal Academy for the year 1707, there is an account of ſome experiments made with fire-arms differently loaded, by M. Caſſini. And among other things he obſerves, that by loading the piece with a ball which is ſomewhat leſs than the caliber, and only laying a little gunpower below the ball and a good deal above it, it will yield a vehement noiſe, but have no ſenſible effect or impulſe on the ball.

Arms, *paſs of*, was a kind of combat in uſe among the ancient cavaliers.

Arms, *ſtand of*, ſignifies a muſket, a bayonet, a ſword, belt, and cartridge box.

Arms denote the natural weapons, or parts of defence, of beaſts: as claws, teeth, tuſks of elephants, beaks of birds, &c.

Arms are alſo uſed figuratively for the profeſſion of a ſoldier. Thus we ſay, he was bred to arms.

Arms, or *Armories*, are alſo uſed in heraldry for marks of dignity and honour, regularly compoſed of certain figures and colours, given or authoriſed by ſovereigns, and borne in banners, ſhields, coats, &c. for the diſtinction of perſons, families, and ſtates; and paſſing by deſcent to poſterity.

They are called arms, in regard they are borne principally on the buckler, cuiraſs, banners, and other aparatus of war.

They are alſo called *coats of arms*, *coat armour*, &c. becauſe anciently embroidered on fur-coats, &c.

Arms, at preſent, follow the nature of titles, which being made hereditary, theſe are alſo become ſo, being the ſeveral marks for diſtinguiſhing of families and kindreds, as names are of perſons and individuals.

Arms are variouſly diſtinguiſhed by the heralds.

Arms *of Alliance*, are thoſe which families or private perſons join to their own, to denote the alliances which they have contracted by marriage.

Arms, *Aſſumptive*, are ſuch as have a right to aſſume of themſelves, arms in virtue of ſome gallant action.

As, if a man who is no gentleman of blood, nor has coat armour, takes a gentleman, lord, or prince, priſoner, in any lawful war, he becomes intitled to bear the ſhield of ſuch priſoner, and enjoy it to him and his heirs. The foundation of which is that principle in military law, that the dominion of things taken in lawful war paſſes to the conqueror.

Arms, *charged*, are ſuch as retain their ancient integrity and value, with the addition of ſome new honourable charge or bearing, in conſideration of ſome noble action.

Arms *of Community*, are thoſe of biſhoprics, cities, univerſities, and other bodies corporate.

Arms *of Conceſſion*, or augmentation of honour, are either entire arms, or elſe one or more figures given by princes, as a reward for ſome extraordinary ſervice.

Arms *of Dominion*, are thoſe which emperors, kings, and ſovereign ſtates bear; being annexed to the territories which they poſſeſs. Thus the three lions, are the arms of England; the fleurs de lys, thoſe of France; the harp, Ireland, &c.

Arms *of Family*, or *Paternal Arms*, are ſuch as belong to a particular family, and which no other perſon has a right to aſſume.

Arms, *full*, or *entire*, are ſuch as retain their primitive purity, integrity, or value; without any alterations, diminutions, or abatements.

It a rule, that the ſimpler and leſs diverſified the arms, the more noble and ancient they are. For this reaſon Garcias Ximenes, firſt king of Navarre, and his ſucceſſors for ſeveral ages, bore only gules, without any figure at all.

The arms of princes of the blood, of all younger ſons, and junior families, are not pure and full; but diſtinguiſhed and diminiſhed by proper differences.

Arms *of Patronage*, are thoſe which governors of provinces, lords of manors, &c. add to their family arms, in token of their peculiar ſuperiority and juriſdiction.

Arms *of Pretenſion*, are thoſe of ſuch kingdoms or territories to which a prince or lord has ſome claim, and which he adds to his own, though the kingdoms or territories are poſſeſſed by a foreign prince or other lord.

Thus the kings of England have quartered the arms of France with their own, ever ſince the claim of Edward III. to that kingdom, in 1330.

Arms *of Succeſſion*, are aſſumed by thoſe who inherit eſtates, manors, &c. by will, entail, or donation, and which they either impale or quarter with their own arms.

Arms are alſo ſaid to be *parted*, *couped*, *quartered*, &c.

Arms are ſaid to be falſe and irregular, when there is ſomething in them contrary to the eſtabliſhed rules of heraldry. As, when metal is put on metal, or colour on colour, &c.

The laws, and other affairs of arms, with the cognizance of offences committed therein, belong to the earl-marſhal and college of arms of theſe realms.

ARMY, ſignifies a great number of ſoldiers, conſiſting of horſe and foot, completely armed, and provided with artillary, ammunition, proviſions, &c. under the command of one general, having lieutenant-generals, major-generals, brigadiers, and other officers, under him.

An army is compoſed of ſquadrons and battalions; and is uſually divided into three corps, and formed into three lines: the firſt line is called the *van-guard*, the ſecond the *main-body*, and the third the *rear-guard* or *body of reſerve*.

The middle of each line is poſſeſſed by the foot; the cavalry form the right and left wing of each line; but ſometimes there are placed ſquadrons of horſe in the intervals between the battalions.

When the army is drawn up in order of battle array, the horſe are placed at five feet diſtance from each other, and the foot at three. In each line the battalions are diſtant from each other 180 feet, which is nearly equal to the extent of their front; and the ſame holds of the ſquadrons, which are about 300 feet diſtant, the extent of their own front. Theſe intervals are left for the ſquadrons and battalions of the ſecond line to range themſelves againſt the intervals of the firſt, that both may more readily march through theſe ſpaces to the enemy: the firſt line is uſually 300 feet diſtant from the ſecond, and the ſecond from the third, that there may be ſufficient room to rally when the ſquadrons and battalions are broken.

This is to be underſtood of a land-army, only. A naval or ſea-army implies a number of ſhips of war, equipped and manned with ſailors, mariners, and marines, under the command of an admiral, with other inferior officers under him.

It has been obſerved, that in Europe a prince with a million of ſubjects cannot keep an army of above 10,000 men, without ruining himſelf. It was otherwiſe in the ancient republics: the proportion of ſoldiers to the reſt of the people, which is now as about 1 to 1000, might then be as about 1 to 8. The reaſon ſeems owing to that equal partition of lands which the ancient founders of commonwealths made among their ſubjects; ſo that every man had a conſiderable property to defend, and means to defend it with: whereas, among us, the lands and riches of a nation being ſhared among a few, the reſt have no way of ſubſiſting but by trades, arts, and the like; and have neither any free property to defend, nor means to enable them to go to war in defence of it, without ſtarving their families. A large part of our people are either artiſans or ſervants, and ſo only miniſter to the luxury and effeminacy of the great. While the equality of land ſubſiſted, Rome, though only a little ſtate, being refuſed the ſuccours which the Latins were obliged to furniſh after the taking of the city in the conſolate of Camillus, preſently raiſed ten legions within its own walls; which was more, Livy aſſures us, than they were able to do in his time, though maſters of the greateſt part of the world. A full proof, adds the hiſtorian, that we are not grown ſtronger; and that what ſwells our city is only luxury, and the means and effects of it.

Our armies anciently were a ſort of militia, compoſed chiefly of the vaſſals and tenants of the lords. When each company had ſerved the number of days or months enjoined by their tenure, they returned home.

The armies of the German empire, conſiſt of divers bodies of troops furniſhed by the ſeveral circles.

The groſs of the French armies, under the Merovingian race, conſiſted of infantry. Under Pepin and Charlemagne, the armies conſiſted almoſt equally of cavalry and foot: but ſince the declenſion of the Carlovingian line, the fees being become hereditary, the national armies, ſays Le Gendre, are chiefly cavalry.

" As it is only by means of a well-regulated ſtanding army that a civilized country can be defended, ſo it is only by means of it that a barbarous country can be ſuddenly and tolerably civilized. A ſtanding army eſtabliſhes, with an irreſiſtible force, the law of the ſovereign through the remoteſt provinces of the empire, and maintains ſome degree of regular government in countries which could not otherwiſe admit of any. Whoever examines with attention the improvements which Peter the Great introduced into the Ruſſian empire, will find that they almoſt all reſolve themſelves into the eſtabliſhment of a well regulated ſtanding army. It is the inſtrument which executes and maintains all his other regulations. That degree of order and internal peace which that empire has ever ſince enjoyed, is altogether owing to the influence of that army.

" Men of republican principles have been jealous of a ſtanding army as dangerous to liberty. It certainly is ſo, wherever the intereſt of the general and that of the principal officers are not neceſſarily connected with the ſupport of the conſtitution of the ſtate. The ſtanding army of Cæſar, deſtroyed the Roman republic; the ſtanding army of Cromwell turned the long parliament out of doors. But where the ſovereign is himſelf the general, and the principal nobility and gentry of the country the chief officers of the army; where the military force is placed under the command of thoſe who have the greateſt intereſt in the ſupport of the civil authority, becauſe they have themſelves the greateſt ſhare of that authority: a ſtanding army can never be dangerous to liberty; on the contrary, it may in ſome caſes be favourable to liberty. The ſecurity which it gives to the ſovereign renders unneceſſary that troubleſome jealouſy which in ſome modern republics ſeems to watch over the minuteſt actions, and to be at all times ready to diſturb the peace of every citizen. Where the ſecurity of the magiſtrate, though ſuppotred by the principal people of the country, is endangered by every popular diſcontent where a ſmall tumult is capable of bringing about in a few hoursa great revolution; the whole authority of government muſt be employed to ſuppreſs and puniſh every murmur and complaint againſt it. To a ſovereign, on the contrary, who feels himſelf ſupported not only by the natural ariſtocracy of the country, but by a well regulated ſtanding army, the rudeſt, the moſt groundleſs, and the moſt licentious remonſtrances, can give little diſturbance. He can ſafely pardon or neglect them, and his conſciouſneſs of his own ſuperiority naturally diſpoſes him to do ſo. That degree of liberty which approaches to licentiouſneſs can be tolerated only in countries where the ſovereign is ſecured by a well regulated ſtanding army. It is in ſuch countries only that the public ſafety does not require that the ſovereign ſhould be truſted with any diſcretionary power for ſuppreſſing even the impertinent wantonneſs of this licentious liberty."

ARNABOS, in the language of medical writers, implies the ſame as cinnamon, which was anciently ſo called in the Greek pharmacopiæs.

ARNALDIA, in medicine, ſignifies a low fever, which occaſioned a dropping off of the hair of the head, attending by pains in the joints, which fully anſwers to the Kentiſh and Cambridgeſhire agues, ſo fatal to ſtrangers who hire themſelves to gather in the harveſt of thoſe countries.

ARNICA, LEOPARDS BANE, in botany, is a genus of the polygamia ſuperflua order, belonging to the ſyngeneſia claſs of plants; and in the natural method ranking under the 49th order, *Compoſitæ diſcoides*. The receptacle is naked; the pappus is ſimple; and the filaments are five, without antheræ.

There are ſeven ſpecies all natives of Ethiopia, except the two following, viz.

1. The montana, with oval leaves, which grows naturally on the Alps, and alſo upon many of the high mountains in Germany, and other cold parts of Europe.

2. The ſcorpioides, with ſawed leaves growing alternately, is a native of Bohemia and Siberia.

The firſt ſpecies delights in a moiſt ſhady ſituation, and may be propagated by roots or ſeeds ſown in autumn.

The ſecond ſort is to be propagated in the ſame manner. Both are very hardy, and require no other care than to be kept free from weeds.

The montana has an acrid bitter taſte, and when bruiſed, emits a pungent odour, which excites ſneezing.

It is recommended in paralytic affections, and in caſes where a loſs or diminution of ſenſe ariſes from an affection of the nerves, as in inſtances of amauroſis, under which circumſtances it ſhould be employed by infuſion.

℞. From a dram to half an ounce of the flowers, may be infuſed in a pint of boiling water, and taken in different doſes in the courſe of the day; ſometimes it produces vomiting, ſweating, or diureſis; but frequently its uſe is attended with no ſenſible operation, unleſs it can be conſidered as ſuch, that in ſome caſes of paralyſis, the cure is ſaid to be preceded by a peculiar prickling, and by ſhooting pains in the affected parts.

Beſides being thus employed, it is repreſented as a powerful antiſpaſmodic; and to have been ſucceſsfully employed in fevers, particularly thoſe of the intermittent kind, and alſo in caſes of gangrene.

In thoſe diſeaſes it is as efficacious as the Peruvian bark, when employed under the form of a ſtrong decoction taken in ſmall doſes frequently repeated, or under the form of an electuary with honey.

ARNOT, in botany, the Engliſh name of the bunium.

ARNULPHIN, in commerce, was a French coin current in the 15th century, and which bore the ſame value as a modern ducat now does in that country, i. e. 4^{s}. 9d. ſterling.

AROLE, ſignifies an American weight, equal to 25 pounds, avoirdupoiſe weight.

AROMA PHILOSOPHORUM, denotes either ſaffron, or the aroph of Paracelſus; as *aroma germanicum* denotes elecampane.

AROMATIC, in medicine and perfumery, is an appellation given to ſuch plants as yield a briſk fragrant ſcent and a warm taſte; as all kinds of ſpices, &c.

AROMATITIS, in ancient phiſiology, indicated a bituminous foſſil, which had much the appearance and effluvia of myrrh. It was common to the countries of Arabia and Egypt, where it was uſed as a faſhionable perfume by the higher orders of people.

AROPH, implies a contraction of *aroma philoſophorum*; a name given to ſaffron.

AROPH, *Paracelſi*, a name given to a kind of chemical flowers, probably of the ſame nature with the Ens Veneris, elegantly prepared by ſublimation from equal quantities of lapis hæmatitis and ſal ammoniac.

AROURA, was an ancient Grecian meaſure of 50 feet. It was more frequently uſed for a ſquare meaſure of half the plethron. The Egyptian aroura was the ſquare of 100 feet.

ARPEGGIO, in muſic, ſignifies the method of cauſing the different ſounds of an accord to be heard ſucceſſively and rapidly, inſtead of ſtriking them all at one time.

ARPENT, ſignifies an acre or furlong of ground; and, according to the old French account in domeſday-book, 100 perches make an arpent. The moſt ordinary acre, called *l' arpent de France*, is 100 perches ſquare: but ſome account it but half an acre.

ARRAIGNMENT, in law, implies the arraigning a perſon to anſwer in form of law upon an indictment preferred before and admitted by the grand inqueſt or jury of a ſhire or corporation. town or city.

When brought to the bar, the criminal is called upon by name to hold up his hand; which, though it may ſeem a trifling circumſtance, yet is of this importance, that by the holding up of his hand he owns himſelf to be of that name by which he is called. However it is not an indiſpenſable ceremony; it being calculated merely for the purpoſe of identifying the perſon, for any other acknowledgement will anſwer the purpoſe as well: therefore, if the priſoner obſtinately and contemptuouſly refuſes to hold up his hand, but confeſſes he is the perſon named, it is fully ſufficient.

Then the indictment is to be read to him diſtinctly in the Engliſh tongue, that he may fully underſtand his charge. After which it is to be demanded of him, whether he be guilty of the crime of which he ſtands indicted, or not?

When a criminal is arraigned, he ſtands mute, confeſſes or pleads to the indictment.

If he will not ſpeak, the court are *ex officio* to impannel a jury to inquire whether he ſtands obſtinately mute, or whether he be dumb, *ex viſitatione Dei*. If the latter appears to be the caſe, the judges of the court are to proceed to the trial, and examine all points as if he had pleaded not guilty.

If he be found to be obſtinately mute, then it is equivalent to a conviction, and, if his crime deſerves it, he ſhall receive judgment and execution.

The Engliſh judgment for ſtanding mute was anciently as follows: " That the priſoner be remanded to the priſon from whence he came, and put into a low, and dark chamber; and there be laid on his back on the bare floor, naked, unleſs where decency forbade; and then there ſhould be placed upon his body as great a weight of iron as he could bear, and more; that he had no ſuſtenance, ſave only, on the firſt day, three morſels of the worſt bread; and, on the ſecond day, three draughts of ſtanding water that ſhould be neareſt to the priſon-door; and in this ſituation this ſhould be alternately his daily diet, *till he died*, or, as anciently the judgment ran, *till he anſwered*."

If the priſoner makes a ſimple and plain confeſſion, the court hath nothing to do but to award judgment: but it is uſually very backward in receiving and recording ſuch confeſſion, out of tenderneſs to the life of the ſubject; and will generally adviſe the priſoner to retract it, and plead to the indictment—Not Guilty.

ARRANGEMENT, or RANGEMENT, in rationals, implies the diſpoſition of the parts of a whole, in certain order.

Modern philoſophy ſhows, that the diverſity of the colours of bodies depends entirely on the ſituation and arrangement of the parts, which reflect the light differently; the diverſity of taſtes and ſmells on the different arrangements of the pores, which render them differently ſenſible; and the general diverſity of bodies on the different arrangements of their parts. Hence, the arrangement of words makes the beauty of diſcourſe.

ARRAS *Hangings*, in commerce and mercantile tranſactions, denote an article imported from the city of Arras, the capital of the county of Artois, in French Flanders. It is properly ſpeaking, a ſuperfine tapeſtry; but of late years, it is become of little uſe in this country, as the ſtaple commodities give ſeveral ſorts of uſeful and ornamental fabrics, which can no where be excelled for beauty of colour, texture, and durability.

ARRAY, in law, implies the ranking or ſetting forth of a jury, or inqueſt of men impanelled on a cauſe.

Battle ARRAY, in military matters, indicates the order or diſpoſition of an army, drawn up with a view to engage the enemy.

ARRAYERS, or ARRAGERS, ARRAITORES, in law, was uſed to imply in ancient ſtatutes, ſuch officers as had the care of the ſoldiers armour, and ſaw them duly accoutred.

In ſome reigns, commiſſioners have been appointed for this purpoſe. Such were the commiſſioners of array appointed by king Charles I. in the year 1642.

ARREARS, in law, ſignifies the remainder of a ſum due, or money remaining in the hands of an accountant. It likewiſe ſignifies the money due for rent, wages, &c. or what remains unpaid of penſions, taxes, &c.

ARRENTATION, in the foreſt law, implies the licenſing the owner of lands in a foreſt to incloſe them with a low hedge and a ſmall ditch, in conſideration of a yearly rent.

ARREST, in Engliſh law, from the French *arreſter*, to *ſtop* or *ſtay*, is the reſtraint of a man's perſon, obliging him to be obedient to the law; and is defined to be the execution of the command of ſome court of record.

An arreſt is the beginning of impriſonment; where a man is firſt taken, and reſtrained of his liberty, under colour of a lawful warrant.

Arreſts are either in *civil* or *criminal* caſes, viz.

1. An arreſt in a *civil cauſe* is reſtraining one's perſon by proceſs in execution of the command of ſome court of record.

An arreſt muſt be by corporal ſeiſing or touching the defendant's body; after which the bailiff may juſtify breaking open the houſe in which he is, to take him: otherwiſe he has no power to raiſe a latch, much leſs to unlock or break a door; but muſt watch his opportunity to arreſt him. For every man's houſe is in law his caſtle of defence and aſylum, wherein he ſhall ſuffer no violence. Which principle is carried ſo far in the civil law, that, for the moſt part, not ſo much as a common citation or ſummons, much leſs an arreſt, can be executed upon a man within his own walls.

Peers of the realm, members of parliament, and corporations, are privileged from arreſts; and of courſe from outlawries. And againſt them the proceſs to inforce an appearance muſt be by ſummons and diſtreſs *infinite*, inſtead of a *capias*.

Likewiſe attornies, and all other perſons attending the courts of juſtice, are not liable to be arreſted by the ordinary proceſs of the court, but muſt be ſued by bill, as being perſonally preſent in court.

Clergymen performing divine ſervice, and not merely ſtaying in the church with a fraudulent deſign, are for the time privileged from arreſts, by ſtatute 50 Edw. III. c. 5. and 1 Rich. II. c. 16.; as are likewiſe members of convocation actually attending thereon, by ſtatute 8 Hen. VI. c. 1.

Suitors, witneſſes, and other perſons, neceſſarily attending any courts of record upon buſineſs, are not to be arreſted during their actual attendance, which includes the neceſſary coming and returning.

Seamen in the king's ſervice are privileged from arreſts for debts under 20l. 1 Geo. II. c. 14. and 14 Geo. II. c. 38.; and ſoldiers or marines are not liable to arreſts for a debt of leſs than 10l. 30 Geo. II. c. 6, 11. Nor can any arreſt be made in the king's preſence, or within the verge of his palace or court, nor in any place where the king's juſtices are actually ſitting.

The king hath a ſpecial prerogative, that he may by his writ of protection privilege a defendant from all perſonal ſuits, for one year at a time, and no longer; in reſpect of his being engaged in his ſervice out of the realm.

The king may alſo by the common law take his creditor into his protection, ſo that no one may ſue or arreſt him till the king's debt is paid: but by the ſtatute 25 Edw. III. c. 19. notwithſtanding ſuch protection, another creditor may proceed to judgment againſt him, with a ſtay of execution, till the king's debt be paid; unleſs ſuch creditor will undertake for the king's debt, and then he ſhall have execution for both.

By 29 Car. II. c. 7. no arreſt can be made, nor proceſs ſerved, upon a Sunday, except for treaſon, felony, or breach of the peace.

2. An arreſt in a *criminal cauſe* is the apprehending or reſtraining one's perſon, in order to be forthcoming to anſwer an alledged crime. To this arreſt all perſons whatſoever are, without diſtinction, equally liable; and doors may be broke open to arreſt the offender: but no man is to be arreſted, unleſs charged with ſuch a crime as will at leaſt juſtify holding him to bail when taken.

There is this difference between arreſts in civil and criminal caſes; that none can be arreſted for debt, treſpaſs, or other cauſe of action, but by virtue of a precept or commandment out of ſome court of record; but for treaſon, felony, or breach of the peace, any man may arreſt with or without warrant or precept; however, in the laſt caſe, it will be hazardous to arreſt, unleſs a warrant is firſt given to a perſon duly authorized to ſerve it on the defendant; for otherwiſe the perſon ſo arreſted, upon proving his innocence may ſue the arreſtor for falſe impriſonment, and of courſe get ample damages.

But the king cannot command any one by word of mouth to be arreſted; for he muſt do it by writ, or order of his courts, according to law: nor can the king arreſt any man on ſuſpicion of treaſon, or felony, as his ſubjects may; becauſe, if he doth wrong, the party cannot have an action againſt him.

Arreſts by private perſons are in ſome caſes commanded. Perſons preſent at the committing of a felony muſt uſe their endeavours to apprehend the offender, under penalty of fine and impriſonment; and they are alſo, with the utmoſt diligence, to purſue and endeavour to take all thoſe who ſhall be guilty thereof out of their view, upon a hue and cry levied againſt them. By the vagrant act 17 Geo. II. c. 5. every perſon may apprehend beggars and vagrants; and every private perſon is bound to aſſiſt an officer requiring him to apprehend a felon.

In ſome caſes arreſts are rewarded by law. For by the 4 and 5 William and Mary, c. 8. perſons apprehending highwaymen, and proſecuting them to a conviction, are intitled to a reward of 40l. and if they are killed in the attempt, their executors, &c. are intitled to the like reward.

By the 6 and 7 William III. c. 17. perſons apprehending counterfeiters and clippers of the coin or coiners, and proſecuting them to conviction, are intitled to 40l.

By 5 Ann. c. 31. perſons who ſhall take any one guilty of burglary, or feloniouſly breaking and entering any houſe in the day-time, and proſecute them to conviction, ſhall receive the ſum of 40l. within one month after ſuch conviction.

With regard to arreſts by public officers, as watchmen, conſtables, &c. they are either made by their own authority, which differs but very little from the power of a private perſon; or by a warrant from a juſtice of peace.

ARREST *of Judgment*, in law, ſignifies the aſſigning juſt reaſon why judgment ſhould not paſs: as, want of notice of the trial; a material defect in the pleading; when the record differs from the deed impleaded; when perſons are miſnamed; where more is given by the verdict than is laid in the declaration, &c. This may be done either in criminal or civil caſes.

ARRESTANDIS *Bonis de diſſipentur*, is a writ which lies for a defendant againſt a plaintiff, in a cauſe at iſſue, by which the former releaſes his cattle or other property ſeized by the latter, who might otherwiſe be at liberty to make ſale of them; but is by this mode prevented from ſo doing, as not being reſponſible for their value, if required by law to give ſatisfaction, from the narrowneſs of his circumſtances.

ARRESTANDO *Ipſum*, ſignifies the bounty paid to a ſeaman on entering on board a ſhip, which holds him covenanted to the king as his ſervant during his wars, ſo that he can be ſecured under this writ if he deſerts from his employment.

ARRESTMENT, in the general acceptation of the word, denotes that diligence by which a creditor detains the goods or effects of his debtor in the hands of third parties, till the debt due to him be either paid or ſecured.

ARRESTO *Facto ſuper bonis*, &c. in law, is a writ brought by a denizen againſt the goods of aliens found within this kingdom, as a recompence for goods taken from him in a foreign country.

ARRESTS, in farriery, are mangy tumors upon a horſe's hinder-legs, between the ham and the paſtern.

ARRIERE BAN, in the French cuſtoms, ſignifies a general proclamation, by which the king may ſummons to the war all that holds of him, as vaſſals, i. e. the nobleſſe, as his vaſſals, and the vaſſals of his vaſſals, or their dependants or tenants.

ARRIERE *Fee*, or *Fief*, in law, is a fee dependent on a ſuperior one. Theſe fees commenced, when the dukes and counts, rendering their governments hereditary in their families, diſtributed to their officers parts of the royal domains which they found in their reſpective provinces, and even permitted thoſe officers to gratify the ſoldiers under them in the ſame manner.

ARROBAS, or Arobas, in commerce, is a weight uſed in Spain, Portugal, and the foreign dominions of both. The Arrobas of Portugal is alſo called Arata, and contains thirty-two Liſbon pounds; that of Spain contains twenty-five Spaniſh pounds. In Peru it is called arroue.

ARRONDEE, in heraldry, is a croſs, the arms of which are compoſed of ſections of a circle, not oppoſite to each other, ſo as to make the arms bulge out thicker in one part than another; but the ſections of each arm lying the ſame way, ſo that the arm is every where of an equal thickneſs, and all of them terminating at the edge of the eſcutcheon like the plain croſs.

ARROW, in war, is a miſſive weapon of offence, ſlender, pointed, and barbed, to be caſt or ſhot with a bow.

Arrow *Makers*, or *Fletchers*, were formerly called bowyers, and were perſons of great conſequence in the commonwealth.

Arrow *Heads and Quarrels* were to be well boched or braſed, and hardened at the points with ſteel; the doing of which ſeems to have been the buſineſs of the arrow ſmith.

Arrow *Head*, in botany, is the ſame as Sagittaria.

Arrow *Root*, in botany, is the ſame with Maranta.

ARSCHIN, in commerce, ſignifies a long meaſure uſed in China to meaſure ſtuffs. Four arſchins make three yards, Engliſh meaſure.

ARSENAL, ſignifies a royal or public magazine, appointed for the making and keeping of arms, neceſſary either for defence or aſſault.

ARSENIC, in mineralogy and chemiſtry, is an heavy opake ſubſtance, uſually ſold in white maſſes, which, when broken, diſcover a ſemi-tranſparency ſomewhat reſembling that of ſal ammoniac, but by expoſure to the air become white and opake like the outſide of the original maſs.

By various chemical proceſſes it may be made to aſſume the appearance either of an acid ſalt or metal, at the pleaſure of the operator; and therefore has been conſidered both as a ſaline ſubſtance and as a ſemi-metal It is not known by whom arſenic was firſt reduced to a metallic form. Paracelſus aſſerts that arſenic, ſublimed with egg-ſhell lime becomes like ſilver; and, in 1675, M. Lemeri makes mention of a method of ſubliming arſenic with fixed alkali and ſoap.

The true nature of arſnic being thus ſo little known, it is no wonder to find chemiſts differing very much as to the claſs of natural bodies in which it ought to be placed. Avicenna and a great number of others claſs it with the ſulphurs; Albertus Magnus and his followers, among the ſalts. Becher conſiders it as a kind of ſoap, or ſaline ſulphureous body. Later experiments, however, have made it evident, that white arſenic conſiſts of an acid united to phlogiſton; and that by diminiſhing the latter, the acid becomes more and more apparent; while, on the contrary, by augmenting the quantity of phlogiſtic matter, the arſenic aſſumes the metallic form.

With reſpect to the ſulphurous nature of arſenic, it appears that the regulus itſelf, as well as orpiment and realgar, are inflammable ſubſtances; but it is not ſo with white arſenic. This inflammability, therefore, which arſenic in a certain ſtate has in common with zinc and ſeveral other ſubſtances, will not denominate it ſulphurous, any more than thoſe of other bodies which poſſeſs the common property of inflammability can be denominated ſulphurs.

This mineral, ſo troubleſome to the mineralogiſt, occaſioned the alchemiſts to ſuſpect the exiſtence of a certain arſenical principle indiſpenſably neceſſary to the perfection of every metal. And even ſo late as 1773 a queſtion to this purpoſe was propoſed by the Royal Academy of Sciences at Berlin: the prize was adjudged to M. Monnet, who in his anſwer conſidered arſenic as a ſemi-metal of a peculiar kind, which is ſo far from conſtituting any aſſential part of metals, that its preſence is always attended with inconveniences, either by carrying off the metal as it flies away, or ſpoiling the maſs in which it remains.

Theſe conſiderations, however, do not hinder us from aſſerting that the acid of arſenic, like others, is a mineralizing ſubſtance, if at any time it happens to meet with metals in the bowels of the earth, and to unite with it in that form.

Arſenic in its pure ſtate is well known to be a moſt deſtructive and deadly poiſon, for which the art of medicine has ſcarcely as yet afforded a cure. Mr. Bergman is of opinion that it acts as an highly corroſive acid, even when applied externally. He alſo tells us, that the dry acid is more deſtructive than white arſenic; the regulus and realgar leſs ſo.

From an experiment of Mr. Scheele, in which eight grains of arſenical acid were given to a cat, it does not appear that it acts more violently than white arſenic. The extreme danger attending this ſubſtance when taken into the human body, ariſes from its inſolubility, and the difficulty of decompounding it; for there can but little danger ariſe from a liquid, unleſs, like corroſive acids, it ſhould at once burn the ſubſtance of the ſtomach like fire; or, like laurel-water ſuſpend the action of the nervous ſyſtem.

Corroſive ſublimate, ſolutions of mercury in aquafortis, &c. will as certainly poiſon as arſenic; but they are much leſs difficult to cure, becauſe any alkaline ſubſtance will certainly decompound them and deſtroy their deleterious efficacy.

Arſenic, on the contrary, cannot be decompounded, nor united with any known ſubſtance, at leaſt in ſuch a ſhort time as the exigence of the caſe we ſpeak of would require, without a conſiderable degree of heat. It will of courſe remain in the ſtomach, continually exerting its miſchievous qualities, unleſs it can be diſcharged by vomiting.

The ſymptoms attending arſenic when ſwallowed are, nauſea, ſickneſs, and retching to vomit, about half an hour after it is taken. Theſe indications are followed by violent vomitings, hiccoughs, and pains in the ſtomach and bowels. Convulſions and palſies of the limbs preſently ſucceed, with intenſe heats, cold ſweats, palpitations of the heart, extreme anxiety, reduction of ſtrength, thirſt and dryneſs of the mouth and throat, loſs of reaſon, and at laſt death.

If the quantity taken is conſiderable, the patient dies in ſeven or eight hours after; and the ſtomach and inteſtines are found, upon diſſection, to be corroded and perforated. When this is not the caſe, violent putrefactive ſymptoms ſoon enſue after arſenic is ſwallowed; for the bodies of thoſe who are poiſoned by it, generally have abundance of red or purple ſpots even before death.

It remarkably inflames the coats of the ſtomach, and the putrefaction is ſaid particularly to take place in the genitals of men.

Mr. Bergman relates, that in the body of a man who was poiſoned with arſenic and diſſected in the anatomical theatre at Upſal, the putrefaction had been ſo ſtrong that the mineral was deprived of part of its phlogiſton, and emitted the garlic ſmell, that peculiar characteriſtic of arſenic when in this ſituation.

Many antidotes have been propoſed againſt this dreadful poiſon by authors of the higheſt reputation; but without that ſucceſs which the confidence of thoſe who propoſed them ſeemed to enſure.

ARSIS and Thesis, in muſic, and proſody, implies a term applied to compoſitions in which one part riſes and the other falls.

ARSMART, in botany, is the ſame as Persicaria.

ARSON, in Engliſh law, is the malicious and wilful burning of the houſe or outhouſe of another man; which is felony in common law.

This is an offence of very great malignity, and much more pernicious to the public than ſimple theft: being an offence againſt that right of habitation which is acquired by the law of nature as well as by the laws of national ſociety; next, becauſe of the terror and confuſion that neceſſarily attends it; and, laſtly, becauſe in ſimple theft the thing ſtolen only changes its owner, but ſtill remains *in eſſe* for the benefit of the public; whereas by burning, the very ſubſtance is abſolutely deſtroyed.

It is in the eye of the law more deſtructive than murder; and of which too it is often the cauſe: ſince murder, atrocious as it is, ſeldom extends beyond the felonious act deſigned; whereas fire too frequently involves in the common calamity perſons unknown to the incendiary, and not intended to be hurt by him, and conſequently friends as well as enemies.

ARSURA, in ancient cuſtoms, is a term uſed for the melting of gold or ſilver, either to refine them, or examine their value.

The method of performing it is explained at large in the black book of the Exchequer, aſcribed to Gervaiſe in the chapter *De Officio Militis Argentarii*, being in thoſe days of great uſe, on account of the various places and different manners in which the king's money was paid.

Arsura, alſo implies the loſs or diminution of metal in infuſion. In this ſenſe, a pound was ſaid *tot ardere denarios*, to loſe ſo many penny-weights.

Arsura likewiſe implies the duſt and ſweepings of ſilverſmiths, and others, who work in ſilver, melted down.

ART is a proper diſpoſal of the things of nature by human thought and experience, ſo as to anſwer the ſeveral purpoſes of mankind; in which ſenſe art ſtands oppoſed to nature.

Art is principally underſtood to be a ſyſtem of rules ſerving to facilitate the performance of certain actions; in which ſenſe it ſtands oppoſed to ſcience, or a ſyſtem of ſpeculative principles.

Art is generally divided into uſeful or mechanic, liberal or polite. The former are thoſe in which the hand and body are more concerned than the mind: of this kind are moſt of thoſe which furniſh us with the neceſſaries of life, and are popularly known by the name of trades; as baking, brewing, carpentry, ſmithery, weaving, &c.

Polite arts are ſuch as depend more on the labour of the mind than that of the hand; and are the produce of imagination; their eſſence conſiſts in expreſſion, and their end is pleaſure. Of this kind are poetry, painting, muſic, &c.

Some of the arts muſt be nearly coeval with the human race; for food, cloathing, and habitation, even in their original ſimplicity, required ſome art. And many other arts are of ſuch antiquity as to place the inventors beyond the reach of tradition.

In all countries where the people are barbarous and illiterate, the progreſs of arts is extremely ſlow.

The progreſs of art ſeldom fails to be rapid, when a people happen to be rouſed out of a torpid ſtate by ſome fortunate change of circumſtances. Proſperity, contraſted with former abaſement, gives to the mind a ſpring, which is vigorouſly exerted in every new purſuit.

The reign of Auguſtus Cæſar, which put an end to the rancour of civil war, and reſtored peace to Rome with the comforts of ſociety, proved an auſpicious æra for literature; and produced a cloud of Latin hiſtorians, poets, and philoſophers, to whom the moderns are indebted for their taſte and talents. One who makes a figure rouſes emulation in all: one catches fire from another, and the national ſpirit is every where triumphant: claſſical works are compoſed, and uſeful diſcoveries made in every art and ſcience. With regard to Rome, it is true, that the Roman government, under Auguſtus was in effect deſpotic: but deſpotiſm, in that ſingle inſtance, made no obſtruction to literature, it having been the politic of that reign to hide power as much as poſſible.

As the progreſs of arts and ſciences toward perfection, is greatly promoted by emulation, nothing is more fatal to an art or ſcience, than to remove that ſpur, as where ſome extraordinary genius appears who ſoars above rivalſhip.

Mechanical arts, in proceſs of time, introduced polite arts; for the profeſſors of the former had beſtowed every convenience, and turned their thoughts to the latter. Beauty was ſtudied in objects of ſight; and men of taſte attached themſelves to the fine arts, which multiplied their enjoyments, and improved their benevolence.

Sculpture and painting made an early figure in Greece; which afforded plenty of beautiful originals to be copied in theſe imitative arts. Statuary, a more ſimple imitation than painting, was ſooner brought to perfection: the ſtatue of Jupiter by Phidias, and of Juno by Polycletes, though the admiration of all the world, were executed long before the art of light and ſhade was known.

Apollodorus, and Zeuxis his diſciple, who flouriſhed in the 15th Olympiad, were the firſt who became eminent in that art. Another cauſe concurred to advance ſtatuary before painting in Greece, viz. a great demand for ſtatues of their gods.

Uſeful arts will never be neglected in a country where there is any polity, for every man finds his account in them. Fine arts are more precarious. They are not reliſhed but by perſons of taſte, who are very few indeed; for which reaſon, they will never flouriſh in any country, unleſs patronized by the ſovereign, or men of power and opulence. They merit ſuch patronage, as one of the ſprings of government; by multiplying amuſements, and humanizing manners; upon which account they have always been encouraged by princes of wiſdom and diſcernment.

The eſſence of the polite arts conſiſts in expreſſion. The end of all theſe is pleaſure; whereas the end of the ſciences is inſtruction and utility.

Some of the polite arts, ſuch as eloquence, poetry, and architecture, are frequently applied to objects that are uſeful, or exercifed in matters that are inſtructive: but in theſe caſes, though the ground-work belongs to thoſe ſciences which employ the underſtanding, yet the expreſſion ariſes from the inventive faculty. This union forms the perfection of the art, according to that ſententious and well known precept of Horace: *Omne tulit punctum, qui miſcuit utile dulci.*

Under the denomination of polite arts, is comprehended oratory, poetry, muſic, painting, ſculpture, engraving, and architecture. Particular deſcriptions of theſe arts are given under their reſpective names.

There is one very eſſential reflection, which it appears proper to make, on the polite arts in general; viz. all the rules in the world are not ſufficient to make a great poet, an able orator, or an excellent artiſt; becauſe the qualities neceſſary to form theſe, depend on the natural diſpoſition, and the fire of genius, which no human art can confer, but which is the pure gift of heaven.

The rules, however, will prevent a man from being a bad artiſt, a dull orator, or a wretched poet; being the reflections of the greateſt maſters in thoſe arts, and that they point out the method by which the ſtudent ſhould exerciſe his talents: and they are of uſe in facilitating his labours, and in directing him to arrive by the ſhorteſt and ſureſt road to perfection. They refine, ſtrengthen, and confirm, his taſte.

Art, founded on juſt and ſagacious rules, gives to nature elegance, dignity, and politeneſs.

Beauty is the object of all the polite arts, and conſiſts, principally, in the agreeable and delightful proportions which are found, 1. Between the ſeveral parts of the ſame objects; 2. Between each part and the whole together; 3. Between the parts and the end or deſign of the object to which they belong.

Genius, or invention, is that faculty of the mind, by which beauty is produced.

Taſte, diſpoſition, or rather the natural ſenſation of the mind, refined by art, ſerves to guide the genius in diſcerning, embracing, and producing, that which is beautiful of every kind.

From whence it follows, that the general theory of the polite arts is nothing more than the knowledge of what they contain that is truly beautiful and agreeable; and it is this knowledge, this theory, which modern philoſophers call by the Latin name of *æſthetica.*

The eſſence of the polite arts conſiſts in expreſſion. This expreſſion lies ſometimes in the words, and ſometimes in the pen; ſometimes in ſounds and their harmony, and at others, in corporeal attitudes; ſometimes in the pencil or in the chiſel, and at others, in the graver; ſometimes in a proper diſpoſition, or judicious employment of the mechanic arts, and at others, merely in their manner of acting the artiſt's part.

Every artiſt ought inceſſantly to labour in the improvement of his taſte or genius; in acquiring that refined diſcernment, by which he will be enabled to diſtinguiſhed the real beauties in each object, the ornaments that are agreeable to it, and the proportions and relations that ſubſiſt analogically in the ſeveral parts: and by this faculty, he will be regulated in the employment of his natural talents.

This labour conſiſts, not only in the profound reflections he muſt make on the properties of objects, as they relate to the fine arts, but alſo in a conſtant, aſſiduous ſtudy of the grand models of beauty.

A very material rule to be obſerved in the practice of the polite arts, is the imitation of nature. Every object in the univerſe has its peculiar nature, of which the artiſt ſhould never loſe ſight in his manner of treating it. In vain will he otherwiſe ornament his work with the moſt refined and moſt brilliant ſtrokes; for, if nature be not juſtly imitated, it will for ever remain imperfect.

In all the polite arts, and the ſubjects they embrace, there muſt neceſſarily reign an elevation of ſentiment, that expreſſes each object in the greateſt perfection of which it is capable, and that imitates nature in her moſt exalted beauty.

The deſign of the fine arts being ſolely to excite pleaſure by the expreſſion of that which is beautiful, every artiſt ſhould therefore raiſe himſelf above his ſubject, and chuſe the moſt favourable light to place it in; beſides, he ſhould embelliſh it with the moſt noble, and beautiful ornaments, that his genius can ſuggeſt; ſtill obſerving a ſtrict imitation of nature.

Art is alſo an appellation given to ſeveral ſuperſtitious practices, as, St. Anſelhm's art, St. Paul's art, &c.

ARTABA, in hiſtory, ſignifies an ancient meaſure of capacity, uſed by the Perſians, Medes, and Egyptians.

ARTADA, or **Artedar**, in pharmacy, implies calcined realgar, uſed in caſes of malignant ulcers, and the cure of the polypus.

ARTEDIA, in botany, is a genus of the digynia order, belonging to the pentandria claſs of plants; and, in the natural method, ranking under the 45th order, Umbellatæ.

The characters generic are the involucra, which are pinnatifid; the floſcules of the diſc are maſculine; and the fruit is hiſpid with ſcales.

There is but one ſpecies, the ſquamata, with ſquamoſe ſeeds, a native of the Eaſt Indies.

It is an annual plant, whoſe ſtalks riſe about two feet high, ſending out a few ſide-branches, which are garniſhed with narrow compound leaves, reſembling thoſe of a daffodil; the extremity of the ſtalk is terminated by a large umbel of white flowers, compoſed of five unequal petals.

ARTEMESIA, in antiquity, were yearly feſtivals obſerved by the Greeks, in honour of Diana, ſurnamed Artemis.

At this feſtival, a mullet was offered as a ſacrifice to the goddeſs, being ſaid to partake of her nature, i. e. hunting. The mullet, it is ſaid, will hunt and kill the ſea-hare or lernia.

ARTEMIA, in ornithology, is the trivial name of the Italian water-fowl, called the avis diomedis, of which it is a ſynonyme.

ARTEMISIA, *Mugwort, Southernwood,* or *Wormwood,* in botany, is a genus of the polygamia ſuperflua order, belonging to the ſyngeneſia claſs of plants; and, in the natural method, ranking under the 49th order, Compoſitæ-nucamentaceæ. The receptacle is either naked, or a little downy; it has no pappus; the calyx is imbricated with roundiſh ſcales; and the corolla has no radii.

There are 23 ſpecies; the moſt material of which are the following:

1. The vulgaris, or common mugwort, grows naturally in many parts of England; it flowers in June, at which time the plant is ready for uſe.

2. The dracunculus, or tarragon, which is frequently uſed in ſallads, eſpecially by the French.

3. The abrotanum, or ſouthernwood, which is kept in gardens for its agreeable ſcent, is a low ſhrub, ſeldom riſing more than three or four feet high, ſending out lateral ſhrubby branches, growing erect, garniſhed with five briſtly leaves, having an agreeable ſcent when bruiſed: the flowers are produced in ſpikes from the extremity of the branches.

4. The ſantonicum produces the ſemen ſantonicum, which is much uſed for worms in children. It grows naturally in Perſia, from whence the ſeeds are brought to Europe.

5. The artemiſia maritima, or ſea-wormwood, grows naturally on the ſea-coaſts in moſt parts of Great Britain, where there are ſeveral varieties, if not diſtinct ſpecies, to be found.

6. The pontica, or pontic wormwood, commonly called Roman wormwood, is a low herbaceous plant, whoſe ſtalks die in autumn, and new ones appear in the ſpring.

7. The abſinthium, or common wormwood, grows naturally

in uncultivated places, and is too well known to require any particular deſcription.

8. The arboreſcens, or tree wormwood, grows naturally in Italy and the Levant, near the ſea.

The other ſpecies are of little note.

The ſouthernwood is propagated by ſlips, planted in a ſhady border about the beginning of April, where they may remain till the following autumn, when they ſhould be tranſplanted where they are to remain. The ſantonicum is likewiſe propagated by ſlips.

The true wormwood is eaſily propagated in the ſame manner.

The other ſorts ſpread by their creeping roots; and require no culture, as they are very hardy, and will thrive any where.

The ſeeds of the ſantonicum are ſmall, light, chaffy, compoſed as it were of a number of thin membranous coats, of a yellowiſh colour, an unpleaſant ſmell, and a very bitter taſte. They are celebrated for anthelmintic virtues.

The leaves of the ſea, common, and Roman wormwood, are uſed as ſtomachics, but are all very diſagreeable.

The diſtilled oil of wormwood is ſometimes made uſe of to rub on the belly as a cure for worms.

The leaves of the vulgaris, or common mugwort, have a light aromatic ſmell, and an herbaceous bitteriſh taſte; and were formerly celebrated as uterine and antihyſteric. This medicine is certainly a very mild one, and conſiderably leſs hot than moſt others to which theſe virtues are attributed. It is now very little employed in medicine; and it is probably with great propriety that the London College of phyſicians have rejected it from their pharmacopœia.

The moxa, ſo famous in the Eaſtern countries for curing the gout by burning it on the part affected, is the lanugo or down growing on the under ſide of the leaves of a ſpecies of mugwort, ſuppoſed to be the ſame with our common ſort.

ARTERIACS, in pharmacy, are medicines ſuited to diſorders of the trachea and the voice.

ARTERIAL, or Arterious, in anatomy, implies ſomething acting in or with the arteries: hence arterial or live blood.

ARTERIOSUS Canalis, in anatomy, implies a tube which leads to the heart of a fœtus, which the foramen ovale ſerves to maintain the circulation of blood, and to convey it from the lungs.

ARTHRITICA, in botany, is ſynonymous with the ground pine; as alſo with the primroſe.

ARTERIOTOMY, in ſurgery, ſignifies the opening an artery, with deſign to procure a diſcharge of blood.

ARTERY, in anatomy, implies a tube or canal which conveys the blood from the heart to all parts of the body.

ARTHRITIS, in medicine, indicates an attack of the gout.

ARTHRODIA, in natural hiſtory, is a genus of imperfect cryſtals, found always in complex maſſes, and forming long ſingle pyramids, with very ſhort and ſlender columns.

Arthrodia, in anatomy, is a ſpecies of articulation, in which the flat head of one bone is received into a ſhallow ſocket in the other. The humerus and ſcapula are joined by this ſpecies of articulation.

ARTICHOKE, in botany, is the ſame as Cinara.

ARTICLE, in human œconomy, implies a clauſe or condition of a contract, treaty, &c. It is alſo a ſmall part or diviſion of a diſcourſe, book, or writing, &c.

Article *of Faith*, in a religious ſenſe, implies a point of chriſtian doctrine, which we are obliged to believe, as having been revealed by God himſelf, and allowed and eſtabliſhed as ſuch by the church.

The thirty-nine articles of the church by England, were founded, for the moſt part, upon a body of articles compiled and publiſhed in the reign of Edward VI. and were firſt paſſed in the convocation, and confirmed by royal authority in the year 1562. They were afterwards ratified anew in the year 1571, and again by Charles I.

The law requires a ſubſcription to theſe articles by all perſons ordained deacons or prieſts, 13 El. cap. 12. and by all clergymen inducted to any eccleſiaſtical living; and by the ſame ſtatute, all licenſed lecturers and curates, 13 El. cap. 12. and 13. and 14. Ch. 2. cap. 4. by the heads of colleges, chancellors, officials and commiſſaries, and ſchool-maſters.

By 1 Will. 3. cap. 18. diſſenting teachers are to ſubſcribe all, except the 34th, 35th, and 36th, and part of the 20th (and in the caſe of Anabaptiſts, except alſo part of the 27th); otherwiſe they are exempted from the benefits of the act of toleration.

Article, in grammar, denotes a particle uſed in moſt languages for the declining of nouns, and denoting the ſeveral caſes and genders thereof.

The uſe of articles ariſes chiefly hence, that in languages which have no different terminations, to expreſs the different ſtates and circumſtances of nouns, there is ſomething required to ſupply that office.

ARTICULATE Sounds, in acouſtics, are ſuch ſounds as expreſs the letters, ſyllables, or words, of any alphabet or language: ſuch are formed by the human voice, and by ſome few birds, as parrots, &c.

ARTICULATION, or Jointing, in anatomy, is the joining of bones together.

Articulation, in botany, is the connection of parts that conſiſt of joints or knees, ſuch as the pods of French honeyſuckles, which when ripe divide into ſo many parts as there are knees or joints; alſo thoſe parts of plants which ſwell into nodes or joints, and which uſually ſend forth branches.

ARTIFICER, a perſon whoſe employment it is to manufacture any kind of commodity, as in iron, braſs, wool, &c. ſuch are ſmiths, braziers, carpenters, &c.

ARTIFICIAL, in a general ſenſe, denotes ſomething made, faſhioned, or produced by art, in contradiſtinction from the productions of nature.

Artificial *Lines*, on a ſector or ſcale, in mathematics, are certain lines ſo contrived, as to repreſent the logarithmic ſines and tangents; which, by the help of the line of numbers, will ſolve all queſtions in trigonometry, navigation, &c. with tolerable exactneſs.

ARTILLERY in its general ſenſe, denotes the offenſive apparatus of war, particularly of the miſſile kind.

In its modern acceptation it ſignifies fire arms, mounted on their carriages and ready for action, with their balls, bombs, grenades, &c.

By artillery is likewiſe underſtood the ſcience which the officers of artillery ought to poſſeſs. Which ſcience teaches to know the nature of all the materials and ingredients relative to artillery, ſuch as, nitre, ſulphur, charcoal; the properties of air and fire; the compoſition and preparation of gun-powder; the materials for fire-works; the conſtruction, proportion, &c. of the different warlike machines; the arrangement, movement, and whole management, of cannon, &c. in the field or in ſieges, in ſuch a manner, that each of them, according to the length of its tube and the diameter of its bore, may be ſituated in the moſt proper place for execution, and that the whole train taken together may reciprocally aſſiſt and ſupport each other with the greateſt advantage.

The hiſtory of the riſe and progreſs of fire arms, comes within the province of Projectiles or Gunnery, to which the reader is referred.

Artillery *Park*, in war, is the place in the rear of both lines in the army, for encamping the artillery, which is drawn up in lines, of which one is formed by the guns; the ammunition-waggons make two or three lines, 60 paces behind the guns, and 30 diſtant from each other; the pontoons and tumbrils make the laſt line. The whole is ſurrounded with a rope which forms the park: the gunners and matroſſes encamp on the flanks; and the bombardeers, pontoon-men, and artificers, in the rear.

Artillery *of Train*, implies a certain number of pieces of ordnance mounted on carriages, with all their tackle, apparel, and furniture fit for marching.

Artillery *Company*, denotes a band of infantry, conſiſting of 600 men, making part of the militia or city-guard of London.

ARTISCUS, *αρτος*, *bread*, in pharmacy, denotes the preparation of viper ſfleſh with bread, in the compoſition of Venice treacle.

ARTIST, or Artisan, in a general ſenſe, denotes a perſon ſkilled in ſome art. In an academical ſenſe, it denotes a philoſopher or proficient in the faculty of arts.

ARTIZOOS, among the faculty, implies an infant who dies as ſoon as it is born. The word is compounded of *αρτι*, *ſhort*, and *ζωη*, *life*.

ARTOCARPUS, in botany, is the bread-fruit tree: a genus of the monandria order, belonging to the monœcia claſs of plants. It has a cylindric amentum or catkin, which thickens gradually, and is covered with flowers; the male and female in a different amentum. In the male, the calyx is two-valved, and the corolla is wanting. In the female, there is no calyx or corolla; the ſtylus is one, and the drupa is many-celled.

Though this tree has been mentioned by many voyagers, particularly Dampier, Rumphius, and Lord Anſon, yet little notice was taken of it till the return of Captain Wallis from the South Seas.

Captain Dampier relates, that in Guam, one of the Ladrone iſlands, "there is a certain fruit called the bread-fruit, growing on a tree as big as our large apple trees, with dark leaves. The fruit is round, and grows on the boughs like apples, of the bigneſs of a penny loaf: when ripe, it turns yellow, ſoft, and ſweet; but the natives take it green, and bake it in an oven till the rind is black: this they ſcrape off, and eat the inſide, which is ſoft and white, like the inſide of new-baked bread, having neither ſeed nor ſtone; but if it is kept above twenty-four hours, it is harſh. As this fruit is in ſeaſon eight months in the year, the natives feed upon no other ſort of bread during that time. They told us that all the Ladrone iſlands had plenty of it. I never heard of it in any other place."

Rumphius, after deſcribing the tree, obſerves, that "the fruit is ſhaped like a heart, and increaſes to the ſize of a child's head. Its ſurface or rind is thick, green, and covered every where with warts of a quadragonal or hexagonal figure, like cut diamonds, but without points. The more flat and ſmooth theſe warts are, the fewer ſeeds are contained in the fruit, and the greater is the quantity of pith, and that of a more glutinous nature. The internal part of the rind, or peel, conſiſts of a fleſhy ſubſtance, full of twiſted fibres, which have the appearance of fine wool; theſe adhere to, and in ſome meaſure form it. The fleſhy part of this fruit becomes ſofter towards the middle, where there is a ſmall cavity formed without any nuts or ſeeds, except in one ſpecies, which has but a ſmall number, and this ſort is not good unleſs it is baked, or prepared ſome other way: but if the outward rind be taken off, and the fibrous fleſh dried, and afterwards boiled with meat, as we do cabbage, it has then the taſte of artichoke bottoms. The inhabitants of Amboyna dreſs it in the liquor of cocoa-nuts; but they prefer it roaſted on coals, till the outward part or peel is burnt. They afterwards cut it into pieces, and eat it with the milk of the cocoa-nut. Some people make fritters of it, or fry it in oil; and others, as the Sumatrians, dry the internal ſoft part, and keep it to uſe inſtead of bread with other food. It affords a great deal of nouriſhment, and is very ſatisfying, therefore proper for hard-working people: and, being of a gentle aſtringent quality, is good for perſons of a laxative habit of body. It is more nouriſhing boiled in our manner, with fat meat, than roaſted on coals.

"The milky juice which diſtils from the trunk, boiled with the cocoa-nut oil, makes a very ſtrong bird-lime.

"This tree is to be found on the eaſtern parts of Sumatra, and, in the Malay language, is called ſoccus and ſoccum capas. It grows likewiſe about the town of Bantam, in Java, and in Balega and Madura, and is known there by the name of ſoccum."

In Anſon's voyage we are informed, "that the rima, or bread-fruit teee, is common in all the Ladrone iſlands, and ſome of the Philippines. It is ſomewhat larger than our apple-tree, and bears a broad, dark-coloured leaf, with five indentures on each ſide. The fruit hangs on boughs, like apples; and of the ſize of a penny loaf, with a thick tough rind, which, when full ripe, turns yellow. The natives gather it before it is quite ripe, and bake it till the cruſt is pretty black; then they raſp it, and there remains a pretty loaf, with a tender yellow cruſt, and the crumb of it is ſoft and ſweet as a new-baked roll: it is without any ſeeds or ſtones.

"This fruit the inhabitants enjoy for about ſeven months; during which they never eat any other kind of bread: but they are obliged to bake it every day; for, when it grows a little ſtale, it becomes harſh and huſky, ſomewhat like the potato-bread made in the weſt of England. There is, however, a remedy for this; which is cutting the loaf into ſlices, when it is new, and drying it in the ſun, by which it is changed into the pleaſanteſt ruſk that can be eaten."

Captain Cook obſerves, that this fruit not only ſerves as a ſubſtitute for bread among the inhabitants of Otaheite, and the neighbouring iſlands in the South Seas, but alſo, variouſly dreſſed, compoſes the principal part of their food. It grows on a tree that is about the ſize of a middling oak, whoſe leaves are frequently a foot and an half long, of an oblong ſhape, deeply ſinuated, like thoſe of the fig-tree, which they reſemble in colour and conſiſtence, and produce a milky juice when broken.

The fruit is about the ſize and ſhape of a child's head; and the ſurface is reticulated, not much unlike a truffle; it is covered with a thin ſkin, and has a core about as big as the haft of a ſmall knife. The eatable part lies between the ſkin and the core; it is extremely white, and ſomewhat of the conſiſtence of new bread; but it muſt be roaſted before it is eaten, being firſt divided into three or four parts; its taſte is inſipid, with a ſlight ſweetneſs, ſomewhat reſembling that of the crumb of wheaten bread mixed with a Jeruſalem artichoke.

This fruit is alſo cooked in a kind of oven, which renders it ſoft, and ſomething like a boiled potatoe; not quite ſo farinaceous as a good one, but more ſo than thoſe of the middling ſort.

Of the bread-fruit they alſo make three diſhes, by putting either water, or the milk of the cocoa-nut to it, then beating it to a paſte with a ſtone peſtle, and afterwards mixing it with ripe plantains, bananas, or the ſour paſte, which they call mahie.

The mahie, which is likewiſe made to ſerve as a ſuccedaneum for ripe bread-fruit before the ſeaſon comes on, is thus made: the fruit of the bread-tree is gathered juſt before it is perfectly ripe; and being laid in heaps, is cloſely covered with leaves: in this ſtate it undergoes a fermentation, and becomes diſagreeably ſweet; the core is then taken out entire, which is done by gently pulling out the ſtalk, and the reſt of the fruit is thrown into a hole which is dug for that purpoſe, and neatly lined in the bottom and ſides with graſs; the whole is then covered with leaves, and heavy ſtones laid upon them; in this ſtate it undergoes a ſecond fermentation, and becomes ſour; after which it will ſuffer no change for many months. It is taken out of the hole as it is wanted for uſe; and, being made into balls, it is wrapped up in leaves, and baked: after it is dreſſed, it will keep five or ſix weeks. It is eaten both cold and hot; and the natives ſeldom make a meal without it, though to Europeans the taſte is as diſagreeable as that of a pickled olive generally is the firſt time it is eaten. The fruit itſelf is in ſeaſon eight months in the year, and the mahie ſupplies the inhabitants during the other four.

To procure this principal article of their food, coſts theſe happy people no trouble or labour, except climbing up a tree: the tree which produces it does not indeed grow ſpontaneouſly; but if a man plants ten of them in his life-time, which he may do in about an hour, he will as completely fulfil his duty to his own and future generations, as a native of our leſs temperate climate can do by ploughing in the cold of winter, and reaping in the ſummer's heat, as often as theſe ſeaſons return; even if, after he has procured bread for his preſent houſhold, he ſhould convert a ſurplus into money, and lay it up for his children.

There are two ſpecies of artocarpus, viz. the inciſus, with gaſhed leaves; and the integrifolia, with entire leaves. There is alſo ſaid to be another diſtinction, into that which bears fruit with ſtones or ſeeds, and that in which the fruit has none. The parts of fructification of that tree which bears the fruit without ſtones, are defective. The amentum, or catkin, which contains the male parts, never expands. The ſtyli, or female part of the fruit, are likewiſe deficient. Hence it may be inferred, that there can be no ſeeds; therefore this tree can only be propagated by ſuckers or layers.

Dr. Solander was aſſured, by the oldeſt inhabitants of Otaheite and the adjoining iſlands, that they well remember there was, formerly, plenty of the ſeed bearing bread-fruit; but they had been neglected upon account of the preference given to the bread-fruit without ſeeds, which they propagate by ſuckers.

ARVALES Fratres, in Roman antiquity, was a college of twelve prieſts, inſtituted by Romulus, and choſen out of the moſt noble families, himſelf being one of that body: they aſſiſted in the ſacrifices of the ambervalia, annually offered to Ceres and Bacchus, for the proſperity of the fruits of the earth; when they wore on their heads crowns made of ears of corn.

The origin of this inſtitution was as follows: Acca Laurentia, Romulus's nurſe, was accuſtomed, once a year, to make a ſolemn ſacrifice for a bleſſing on the fields; her twelve ſons always aſſiſting her in the ſolemnity; but at laſt, loſing one of her ſons, Romulus offered himſelf to ſupply his place, and gave this ſmall ſociety the name of Arvales Fratres.

This order was in great repute at Rome: they held the dignity for life, and never loſt it upon account of impriſonment, baniſhment, or any other accident.

ARVIL Supper, in Engliſh cuſtoms, ſignifies a feaſt or entertainment, made at funerals in the north of England. Arvil bread is the bread delivered to the poor at funeral ſolemnities: and arvil, arval, arſal, are uſed for the burial or funeral rites.

ARUM, Wakerobin, or Cuckow Pint, in botany, is a genus of the polyandria order, belonging to the gynandria claſs of plants, and, in the natural method, ranking under the 2d order, Piperitæ.

The ſpatha is monophyllous, and cowl-ſhaped; the ſpadix is naked above, female below, and ſtamened in the middle.

There are 22 ſpecies, of which the following are the principal.

1. The maculatum, or common wake-robin, grows naturally in moſt parts of Great Britain. The leaves are halberd-ſhaped, and ſpotted; the berries numerous, growing in a naked cluſter. The flowers appear in April; and their wonderful ſtructure hath given riſe to many diſputes among the botaniſts. The receptacle is long, in the ſhape of a club, with the ſeed-buds ſurrounding its baſe. The chives are fixed to the receptacle, amongſt the ſeed-buds, ſo that there is no occaſion for the tips to be ſupported upon threads, and therefore they have none; but they are fixed to the fruit-ſtalk, and placed between two rows of tendrils: the point in diſpute is, what is the uſe of thoſe tendrils?

2. The proboſcidium.

3. The ariſarium.

4. The tenuifolium.

Theſe three ſpecies have uſually been ſeparated from this genus, and diſtinguiſhed by the general name of ariſarum, or friar's cowl, on account of the reſemblance of their flowers to the ſhape of the cowls worn by friars.

5. The italicum, is a native of Italy, Spain, and Portugal.

6. The dracunculus, or common dragons, grows naturally in moſt of the ſouthern parts of Europe.

7. The trilobatum, or arum of Ceylon, is a native of that iſland and ſome other parts of India.

8. The colocaſia.

9. The divaricatum, with ſpear-ſhaped leaves.

10. The peregrinum, or elder.

11. The eſculentum, or eatable arum.

12. The ſagittifolium, or greateſt Egyptian arum. All theſe ſpecies have mild roots, which are eaten by the inhabitants of the hot countries, where they grow naturally; and ſome of them are cultivated by the inhabitants of the ſugar colonies, where their roots are conſtantly eaten, as alſo the leaves which they call Indian kale; which, in thoſe countries, proves a good ſuccedaneum for European eſculent plants.

13. The arboreſcens, or dumb cane, is a native of the ſugar iſlands and warm parts of America, where it grows chiefly on low grounds.

All the ſpecies of this plant are hardy, except the trilobatum and the arboreſcens. The former muſt be kept conſtantly in a ſtove, and the laſt in a moderate hot bed. The arboreſcens is propagated by cutting off the ſtalks into lengths of three or four joints, which muſt be left to dry ſix weeks or two months; for if the wounded part is not perfectly healed over before the cuttings are planted, they will rot and decay.

The roots of the maculatum and dracunculus are uſed in medicine, and differ in nothing but that the latter is ſomewhat ſtronger than the former.

All the parts of the arum, particularly the root, have an extremely pungent, acrimonious taſte; if the root be but lightly chewed, it continues to burn and vellicate the tongue for ſome hours, occaſioning at the ſame time a conſiderable thirſt: theſe ſymptoms are alleviated by butter, milk, or oily liquors.

This root is a powerful ſtimulant and attenuant. It is reckoned a medicine of great efficacy in ſome cachectic and chlorotic caſes, in weakneſs of the ſtomach occaſioned by a load of viſcid phlegm. Great benefit has been obtained from it in rheumatic pains, particularly thoſe of the fixed kind.

In theſe caſes it may be given from 10 grains to a ſcruple of the freſh root twice or thrice a-day, made into a bolus or emulſion with unctuous and mucilaginous ſubſtances, which cover its pungency, and prevent its making any painful impreſſion on the tongue.

It generally excites a ſlight tingling ſenſation through the whole habit, and, when the patient is kept warm in bed, produces a copious ſweat.

ARUNDEL *Oil*, in the materia medica, is the produce of a tree that grows at Bombay, Gambroon, and Surat, in the Eaſt Indies, incloſed in a rough huſk; and the kernel of the nut yields an oil, which is of a purgative nature. A tea ſpoonful of it is reckoned a doſe.

ARUNDELIAN Marbles, Oxford Marbles, or Parian Chronicle, are ancient ſtones, on which is inſcribed a chronicle of the city of Athens, engraven in capital letters in the iſland of Paros, one of the Cyclades, 264 years before Jeſus Chriſt. They take their firſt name from Thomas Earl of Arundel, who procured them out of the Eaſt, or from Henry his grandſon, who preſented them to the univerſity of Oxford.

The Arundelian Marbles, in their perfect ſtate, contained a chronological detail of the principal events of Greece during a period of 1318 years, beginning with Cecrops, before Chriſt 1582 years, and ending with the archonſhip of Diognetus, before Chriſt 264. But the chronicle of the laſt 90 years is loſt; ſo that the part now remaining ends at the archonſhip of Diotimus, 354 years before the birth of Chriſt: and in this fragment the inſcription is at preſent ſo much corroded and effaced, that the ſenſe can only be diſcovered by very learned and induſtrious antiquaries.

This chronicle, and many other relics of antiquity, real or pretended, were purchaſed in Aſia Minor, in Greece, and in the iſlands of the Archipelago, by Mr. William Petty, who in the year 1624 was ſent by Thomas Earl of Arundel for the purpoſe of making ſuch collection for him in the Eaſt. They were brought into England about the beginning of the year 1627, and placed in the gardens belonging to Arundel-houſe in London.

Soon after their arrival they excited a general curioſity, and were viewed by many learned men; among others by Sir Robert Cotton, who prevailed upon Mr. Seldon to employ his abilities in explaining the Greek inſcriptions. Selden and two of his friends, Patrick Young, and Richard James, immediately commenced their operations, by cleaning and examining the marble containing the Smyrnean and Magneſian league, and afterwards proceeded to the Parian chronicle. The following year Selden publiſhed a ſmall volume in quarto, including about 39 inſcriptions copied from the marbles.

In the turbulent reign of Charles I. and the ſubſequent uſurpation, Arundel-houſe was often deſerted by the illuſtrious owners; and, in their abſence, ſome of the marbles were defaced and broken, and others either ſtolen or uſed for the ordinary purpoſes of architecture. The chronological marble, in particular, was unfortunately broken and defaced. The upper part, containing 31 epochas, is ſaid to have been worked up in repairing a chimney in Arundel-houſe.

In the year 1667, the Hon. Henry Howard, afterwards Duke of Norfolk, the grandſon of the firſt collector, preſented theſe ſuppoſed remains of antiquity to the univerſity of Oxford.

Selden's work becoming very ſcarce, Biſhop Fell engaged Mr. Prideaux to publiſh a new edition of the inſcriptions, which was printed at Oxford in 1676. In 1732 Mr. Maittaire obliged the public with a more comprehenſive view of the marbles than either of his predeceſſors. Laſtly, Dr. Chandler publiſhed a new and improved copy of the marbles in 1763, in which he corrected the miſtakes of the former editors; and in ſome of the inſcriptions, particularly that of the Parian chronicle, ſupplied the *lacunæ* by many ingenious conjectures.

The Arundelian marbles have generally been regarded as a curious monument of antiquity. They were, however, diſcovered in ſome inſtances to be inconſiſtent with the moſt authentic hiſtorical accounts; Sir Iſaac Newton and ſeveral other modern philoſophers paid little or no regard to them; and of late their abſolute authenticity has been ſeverely queſtioned in an expreſs diſſertation upon the ſubject, entitled The Parian Chronicle. In this diſſertation, much ingenuity as well as judgment, and a great extent of ancient learning are diſplayed.

ARUNDO, the Reed, in botany, is a genus of the digynia order, belonging to the triandria claſs of plants; and in the natural method ranking under the 4th order, Gramina. The calyx conſiſts of two valves, and the floſcules are thick and downy.

There are four ſpecies, viz. 1. The phragmitis, or common marſh-reed, grows by the ſides of the rivers and in ſtanding waters.

2. The donax, or manured reed, is a native of warm countries, but will bear the cold of our moderate winters in the open air. It dies to the ſurface in autumn, but appears again in the ſpring, and, if kept ſupplied with water, will grow 10 or 12 feet high in one ſummer.

3. The verſicolor, or Indian variegated reed, is ſuppoſed to be a variety of the ſecond, differing from it only in having variegated leaves.

4. The bambos, or bamboo, is a native of the Eaſt Indies and ſome parts of America; where it frequently attains the height of 60 feet. The main root is long, thick, jointed, ſpreads horizontally, and ſends out many cylindrical woody fibres, of a whitiſh colour, and many feet long. The flowers are produced in large panicles from the joints of the ſtalks, placed three in a parcel cloſe to their receptacles: they reſemble thoſe of the common reed, and are ſucceeded by ſeeds of the ſame form ſurrounded with down. The pods are pickled, and what are called achian by the Eaſt Indians.

The ſmaller ſtalks are uſed for walking ſticks. The inhabitants of Otaheite make flutes of them, about a foot long, with two holes only, which they ſtop with the firſt finger of the left hand and the middle one of the right, and they blow through their noſtrils.

5. The arborea, with a tree-like ſtalk, differs from the former only in having narrower leaves.

6. The orientalis is what the Turks uſe as writing-pens; it grows in a valley near mount Athos, as alſo on the banks of the river Jordan. None of theſe plants are at preſent to be found in Great Britain.

Arundo *Saccharifera*, or *Sugar-cane*, is the ſame as Saccharum.

ARUSPICES, or Haruspices, in Roman antiquity, were an order of prieſts who pretended to foretel future events by inſpecting the intrails of victims killed in ſacrifice; they were alſo conſulted on occaſion of portents and prodigies.

The Haruſpices were always choſen from the beſt of families; as their employment was of the ſame nature as that of the augurs, they were as much honoured.

Their college, as well as thoſe of the other religious orders, had its particular regiſters and records.

ARVUM, in agriculture, implies all the land which is actually in tillage, thereby contradiſtinguiſhing ſuch land, from meadow, and paſture ground.

ARX, in the ancient military art, ſignifies a town, fort, or caſtle of defence.

Arx alſo denoted a conſecrated place on the Palatine Mount, where the augurs publicly performed their office.

ARYTÆNOIDES, in anatomy, is the name of two cartilages, which, together with others, conſtitute the head of the larynx.

ARYTHMUS, in medicine, ſignifies the want of a juſt modulation in the pulſe. It is oppoſed to *eurythmus*, a pulſe modelated agreeably to nature.

AS, in antiquity, implies a particular weight, conſiſting of 12 ounces; being the ſame with the *libra*, or the Roman pound.

As, was alſo a Roman coin, which was of different weights and different matter in different ages of the commonwealth.

In the time of Tullus Hoſtillius, it was of braſs, and called *as*, *libra*, *libella*, or *pondo*, becauſe actually weighing a pound or 12 ounces. Four hundred and twenty years after, the firſt Punic war having exhauſted the treaſury, they reduced the *as* to two ounces. In the ſecond Punic war, Hannibal preſſing very hard upon them, they reduced the *as* to half its weight, viz. to one ounce. And laſtly, by the Papirian law, they took away half an ounce more, and conſequently reduced the *as* to the diminutive weight of half an ounce: and it is generally thought that it continued the ſame during the commonwealth, and even till the reign of Veſpaſian.

Its original ſtamp was that of a ſheep, ox, or ſow: but from the time of the emperors, it had on one ſide a Janus with two faces, and on the reverſe the roſtrum or prow of a ſhip.

As, alſo denoted any integer or whole. Whence the Engliſh word *ace*. Thus *as* ſignified the whole inheritance; whence *hæres ex aſſe*, the heir to the whole eſtate.

ASA, or Assa, in the materia medica, is a name given to two very different ſubſtances, called *aſa-dulcis* and *aſa-fœtida*.

Asa *Dulcis* is the ſame with Benzoin.

Asa *Fœtida* is the concrete juice of a large embelliferous plant, growing in ſeveral parts of Aſia.

Asa, among naturaliſts, an odoriferous and fragrant gum.

ASAPPES, or Azapes, ſignify an order of ſoldiers in the Turkiſh army, whom they always expoſe to the firſt ſhock of the enemy; to the end that the enemy being thus fatigued, and their ſwords blunted, the ſpahis and janiſaries may fall on and find an eaſy conqueſt.

ASAROTA, ασαρωτα from α and σαιρω, *I ſweep*, were a kind of painted pavements in uſe before the invention of Moſaic work.

The moſt celebrated was that at Pergamus, painted by Seſus, and exhibiting the appearance of crumbs, as if the floor had not been ſwept after dinner, whence, according to Pliny, the denomination. Perault ſuppoſes them to have been a black kind of pavements of a ſpongy matter.

ASARUM, **Asarabacca**, in botany, is a genus of the monogynia order, belonging to the dodecandria claſs of plants. The calyx is trifid or quadrifid, and reſts on the germen; there is no corolla; the capſule is leathery and crowned. There are three ſpecies, viz. the Europeum, the Canadenſe, and Virginicum. The firſt grows naturally in England. It has a thick fleſhy jointed root; the leaves grow ſingly upon ſhort foot ſtalks, which ariſe immediately from the root: the flowers grow cloſe to the ground, ſo are hid under the leaves. They have a bell-ſhaped implement, of a purple colour, which is cut into three parts at the top, where it turns backward. It grows in a moiſt ſhady place, and may be propagated by parting the roots in autumn.

The two other ſpecies have no remarkable properties.

Both the roots and leaves have a nauſeous, bitter, acrimonious, hot taſte; their ſmell ſtrong, and not diſagreeable. Given in ſubſtance from half a dram to a dram, they cauſe the patient to evacuate powerfully both upwards and downwards.

The principal uſe of this plant in medicine is a ſternutatory. The root of which is perhaps the ſtrongeſt of all the vegetable errhines, white hellebore itſelf not excepted. Snuffed up the noſe, in quantity of a grain or two, it occaſions a large evacuation of mucus, and raiſes a plentiful ſpitting. The leaves are conſiderably milder, and may be uſed to the quantity of three, four, or five grains.

The leaves are the principal ingredient in the *pulvis ſternutatorius*, or *pulvis aſari compoſitus*, as it is now called, of the ſhops.

ASASI, in botany, ſignifies a tree or ſhrub, which grows on the coaſt of Guinea in Aſia, being ſo called by the natives, which in their language implies, a tooth healer; for the leaves boiled in water, and applied to the teeth and gums, inſtantly remove the diſagreeable pain called the tooth ach. The tree bears a very great reſemblance to laurel, with this difference, that the branches and leaves have reddiſh ſpots that are protuberant to the touch.

ASBESTINE, in pyrotechny, implies any thing that is incombuſtible, ſuch as the *lapis abeſtos*, and other adamantine ſubſtances that are fire proof.

ABESTOS, in natural hiſtory, is a ſort of native foſſile ſtone, which may be ſplit into threads and filaments, from one inch to ten in length, very fine, brittle, ſomewhat tractable, ſilky, and of a greyiſh colour, not unlike talc of Venice. It is inſipid to the taſte, indiſſoluble in water, and endued with the wonderful property of remaining unconſumed in the fire, which only whitens it.

The abeſtos is found in Crete and Cyprus; in Tartary; at Namur in the Low Countries; in Thuringia among the mines; in the Old Noricum; in Egypt; in the mountains of Arcadia; at Puteoli; in the iſland of Corſica; in the iſland of Angleſey in Wales; in Aberdeenſhire in Scotland; at Montauban in France; and in the kingdom of Siberia.

ASCARIS, or **Ascaides**, in zoology, is a genus of inſects belonging to the order of vermes inteſtina. The body of the aſcaris is cylindrical, filiform, and tapers at both ends.

The ſpecies are two, viz. 1. The vermicularis, with faint annular rugæ, and the mouth tranſverſe, is about a quarter of an inch long, and thicker at one end than the other. It is found in boggy places, in the roots of putrid plants, and very frequently in the rectum of children and horſes. It emaciates children greatly, and is ſometimes vomited up.

2. The lumbricoides is about the ſame length with the lumbricus terreſtris, or common earth worm; but it wants the protuberant ring towards the middle of the body, the only mark by which they can properly be diſtinguiſhed. The body of the lumbricoides is cylindrical, and ſubulated at each extremity; but the tail is ſomewhat triangular. The lumbricoides is the worm which is moſt commonly found in the human inteſtines. It is viviparous, and produces vaſt numbers.

ASCENDANT, in aſtrology, denotes the horoſcope, or degree of the ecliptic which riſes upon the horizon at the time of the birth of any one. This is ſuppoſed to have an influence on the perſon's life and fortune, by giving him a bent and propenſity to one thing more than another.

Ascendant, in a moral ſenſe, implies a certain ſuperiority which one man has over another, from ſome unknown cauſe.

ASCENDANTS, in law, are oppoſed to deſcendants in ſucceſſion; i. e. when a father ſucceeds his ſon, or an uncle his nephew, &c. heritage is ſaid to aſcend, or to go to aſcendants.

ASCENDING, in aſtronomy, is ſaid of ſuch ſtars as are riſing above the horizon in any parallel of the equator.

Ascending *Latitude*, is the latitude of a planet when going towards the north pole.

Ascending *Node*, is that point of a planet's orbit, in which it paſſes the ecliptic, and ſo proceeds northward.

Ascending *Veſſels*, in anatomy, are thoſe which carry the blood upwards; as the aörta aſcendens.

ASCENSION, in aſtronomy, is either right or oblique. Right aſcenſion of the ſun, or a ſtar, is that degree of the equinoctial, counted from the beginning of aries, which riſes with the ſun or ſtar in a right ſphere. Oblique aſcenſion is an arch of the equator intercepted between the firſt point of aries and that point of the equator which riſes together with a ſtar in an oblique ſphere.

Ascension *Day* ſignifies a feſtival of the Chriſtian church, held ten days before Whitſuntide, in memory of our Saviour's aſcenſion into heaven after his reſurrection.

ASCENSIONAL Difference, in aſtronomy, is the difference between the right and oblique aſcenſion of the ſame point to the ſurface of the ſphere.

ASCENT, in a general ſenſe, implies the motion of a body upwards, or the continual receſs of a body from the earth.

Thus Peripatetics attribute the ſpontaneous aſcent of bodies to a principle of levity inherent in them. The modern philoſophers deny any ſuch thing as ſpontaneous levity; and ſhow, that whatever aſcends, does it by virtue of ſome external impulſe or extruſion.

Thus ſmoke and other rare bodies aſcend in the atmoſphere; and oil, light woods, &c. in water; not by any external principle of levity, but by the ſuperior gravity or tendency downwards of the parts of the medium in which they are.

The aſcent of light bodies in heavy mediums is produced after the ſame manner as the aſcent of the lighter ſcale of a balance. It is not that ſuch ſcale has an internal principle by which it immediately tends upwards; but it is impelled upwards by the preponderancy of the other ſcale; the exceſs of the weight of the one having the ſame effect, by augmenting its impetus downwards, as ſo much real levity in the other; the tendencies mutually oppoſing each other, ſo that action and reaction are always equal.

Ascent *of Bodies on Inclined Planes*, are explained under the Syſtem of MECHANICS.

Ascent *of Fluids*, under the article HYDROSTATICS.

Ascent *of Vapours*, under the article EVAPORATION.

ASCESIS, in medical language, properly denotes exerciſe of the body. It is formed from the verb *ασκειν*, uſed by the ancients in ſpeaking of the ſports and combats of the athletæ.

Ascesis is alſo uſed by philoſophers, to denote an exerciſe conducive to virtue, or to acquire a greater degree of virtue.

ASCETERIUM, in eccleſiaſtical hiſtory, frequently implies a monaſtery, or place ſet apart for the exerciſes of virtue and religion. The word is formed from aſceſis, exerciſe; or aſcetra, one who performs exerciſe. Anciently it ſignified a place where the athletæ or gladiators performed their exerciſes.

ASCETIC, is an ancient appellation given to ſuch perſons as, in the primitive times, devoted themſelves more immediately to the exerciſes of piety and virtue, in a retired life; and particularly to prayer, abſtinence, and mortification.

Ascetic is alſo a title of ſeveral books of ſpiritual exerciſes. As, the Aſciatics, or devout exerciſes of St. Baſil, archbiſhop of Cæſarea in Cappadocia, &c.

ASCHARIANS, in the Mahomedan code, imply the followers of a celebrated doctor of that ſect called Aſcharius.

ASCHIA, in ichthyology, is a ſynonyme or trivial name of the Grayling.

ASCIA, in antiquity, ſignifies the axe which the Roman ſculptors uſed to act and hew their tomb ſtones with, generally repreſented on the head ſtone of deceaſed perſons.

Ascia, in ſurgery, implies a crooked or uneven bandage put upon a certain part for ſome particular purpoſe, ſo that all bandages or poultices, uſed in the art of healing, may be ſaid to be, for ſome cauſe or other, Aſciatical applications, as there is a mode of form to be uſed, with proper changes, in every caſe that can poſſibly fall within the caſualties of human nature; for no two diſeaſes or accidents are exactly the ſame, therefore no two applications or cures can be alike.

ASCIDIA, implies a genus of animals belonging to the order of vermes molluſca. The body is cylindrical, and fixed to a ſhell, rock, &c. It has two appertures; one on the ſummit, the other lower, forming a ſheath.

There are ſix ſpecies, viz. the papilloſum, gelatinoſum, inteſtinalis, quadridentata, ruſtica, and echinata, only one of which, viz. the ruſtica, is found in the Britiſh ſeas. Animals of this genus have the faculty of ſquirting out the water they take in. The expanſion and contraction of their bodies occaſion their aſſuming various forms.

ASCII, among geographers, is an appellation given to thoſe inhabitants of the earth who, at certain ſeaſons of the year, have no ſhadow; ſuch are all the inhabitants of the torrid zone, when the ſun is verticle to them.

ASCINIS *Piſcis*, in ichthyology, is a trivial name for the eglifirnes, or haddock, of which it is a ſynonyme.

ASCITÆ, in antiquity, were a ſect of the Montaniſts, who appeared in the ſecond century. They were ſo called, becauſe they introduced a kind of Bacchanals into their aſſemblies, who danced round a bag or ſkin blowed up; ſaying, they were thoſe new bottles filled with new wine, of which our Saviour makes mention, Matth. ix. 17; they are ſometimes alſo called Aſcodrogitæ.

ASCITES, in medicine, ſignifies the dropſy of the abdomen.

ASCLEPIA, in mythology, was a feſtival of Æſculapius the god of phyſic, obſerved particularly at Epidaurus, where it was attended with a conteſt between the poets and muſicians, whence it was likewiſe called Ιερος Αγων, *the ſacred contention.*

ASCLEPIAD, in ancient poetry, implied a verſe compoſed of four feet, the firſt a ſpondee, the ſecond a choriambus, and the two laſt dactyls; or of four feet and a cæſura, the firſt a ſpondee, the ſecond a dactyl, after which the cæſura, then the two dactyls; as, *Mæcenas atavis edite regibus.*

ASCLEPIAS, Swallow-Wort, in botany, is a genus of the digynia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 30th order, Contortæ. The generic character is taken from five oval, concave, horn-like nectaria which are found in the flower.

There are 19 Species, viz.

1. The alba, or common ſwallow-wort, which has a root compoſed of many ſtrong fibres connected at top like thoſe of aſparagus, from whence ariſe many ſtalks, in number proportional to the ſize of the roots, which grow two feet high, and are very ſlender at the top: the leaves are placed oppoſite by pairs; the flowers white, growing in umbels near the top of the ſtalk, from whence are ſent out ſmaller umbels.

After the flower is paſt, the two germens become long pointed pods, incloſing many compreſſed ſeeds lying imbricatim, which are crowned with a ſoft white down.

It flowers in June, and the ſeeds ripen in September.

It is a native of the ſouth of France, Spain, and Italy.

2. The Syriaca, or greater Syrian dogſbane, is a perennial plant.

3. The curraſſavica, or baſtard ipecacuanha, is a native of the warm parts of America.

The other ſpecies are not worth enumerating, being of little or no value.

The root of the firſt ſpecies is uſed in medicine. The root has a ſtrong ſmell, eſpecially when freſh, approaching to that of valerian, or nard; the taſte is at firſt ſweetiſh and aromatic, but ſoon becomes bitteriſh, ſub-acrid, and nauſeous. It is eſteemed ſudorific, diuretic, and emmenagogue: it is alſo frequently employed by the French and German phyſicians as an alexipharmic, and ſometimes as a ſuccedaneum to contrayerva, whence it has received the name of Contrayerva Germanorum.

ASCODUTÆ, in antiquity, were a ſect of heretics, in the ſecond century, who rejected all uſe of ſymbols and ſacraments, on this principle, that incorporeal things cannot be communicated by things corporeal, nor divine myſteries by any thing viſible.

ASCOLIA, in Grecian antiquity, was a feſtival celebrated by the Athenian huſbandmen in honour of Bacchus, to whom they ſacrifice a he-goat, becauſe it deſtroys the vines; and, to ſhow the greater indignity to an animal hated by Bacchus, the peaſants, after having killed him, made a foot-ball of his ſkin. Virgil has beautifully deſcribed the occaſion of the ſacrifice, and manner of celebrating the feſtival.

ASCRIPTITII, or Adscriptitii, in law, ſignify a kind of aliens or foreigners newly admitted to the freedom of a city or country.

Ascriptitii, in the Roman military laws, ſignify the recruits appointed to ſupply the loſſes of the legions, called alſo *accenſi*.

ASCYRUM, Peter's-wort, in botany, a genus of the polyandria order, belonging to the polydelphia claſs of plants; and in the natural method ranking under the 20th order, Rotaceæ.

The calyx conſiſts of four leaves; the corolla has four petals; the filaments are numerous, and divided into four bundles.

There are three ſpecies, the crux andreæ, the hypericoides, and the villoſum, all natives of the Weſt Indies or America, but poſſeſſing no property worthy of notice.

ASEKI, or Asekai, imply the name which the Turks give to the favourite ſultaneſſes who have brought forth ſons. Theſe are greatly diſtinguiſhed above others in their apartments, attendants, penſions, and honours.

The ſultana who firſt preſents the emperor with a male child, is reckoned the chief favourite, is called *buyuk aſeki*, and ranks as a legitimate wife: though, from the time of Bajazet I. the ſultans are forbid to marry by a public law, which Solyman II. violated in favour of Roxalana.

ASELLUS, in zoology, ſignifies the trivial name of a ſpecies of oniſcus.

ASH, in botany, is the ſame as Fraxinus.

Ash *Hole*, among chemiſts, ſignifies the loweſt part of a furnace; and is intended to receive the aſhes falling from the fire, and to give a paſſage to the air which is to be introduced into the furnace, to keep up the combuſtion.

Ash *Wedneſday*, ſignifies the firſt day of Lent; ſuppoſed to have been ſo called from a cuſtom in the church, of ſprinkling aſhes that day on the heads of penitents then admitted to penance.

ASHES, are the earthy particles of combuſtible ſubſtances after they have been burnt.

If the aſhes are produced from vegetable bodies, they contain a conſiderable quantity of fixed ſalt, blended with the terrene particles: and from theſe aſhes the fixed alkaline ſalts called pot-aſh, pearl-aſh, &c. are extracted.

The aſhes of all vegetables are vitreſiable, and found to contain iron. They are alſo an excellent manure for cold and wet grounds.

Several religious ceremonies depend upon the uſe of aſhes. St. Jerome relates, that the Jews in his time rolled themſelves in aſhes, as a ſign of mourning.

To repent in ſackcloth and aſhes, is a frequent expreſſion in Scripture for mourning and being afflicted for our ſins.

There was a ſort of lye and luſtral water made with the aſhes of an heifer ſacrificed upon the great day of expiation; the aſhes of which were diſtributed to the people, and this water was uſed in purifications as often as any touched a dead body, or was preſent at funerals, Numb. xix. 17. The Pſalmiſt in great ſorrow ſays, that he had eaten aſhes as if it were bread, Pſ. cii. 9.; which, however, is to be conſidered as an hyperbole. He ſat on aſhes, he threw aſhes on his head; his food, his bread, was ſpoiled with the aſhes wherewith he was covered.

The ancient Perſians had a ſort of puniſhment for ſome great criminals, which conſiſted in executing them in aſhes. 2 Mac. xiii. 5, 6.

ASHLAR, is a term uſed among builders; by which they imply free ſtone, as they come out of the quarry of different lengths and thickneſſes.

ASHLERING, among builders, ſignifies quartering, to lath to, in garrets, about two and a half, or three feet high, perpendicular to the floor, up to the under ſide of the rafters.

ASIARCHÆ, in antiquity, termed by St. Paul, Chief of Aſia, Acts xix. 31. were the Pagan Pontifs of Aſia, choſen to ſuperintend and have the care of the public games; which they did at their own expence; upon which account they were always the richeſt and moſt conſiderable men of the towns.

ASIDE, in the drama, implies ſomething ſaid by an actor, which ſome of the other actors preſent, are ſuppoſed not to hear.

ASILUS, or Hornet-fly, in entomology, is a genus of inſects belonging to the order of inſecta diptera. It has two wings; and a horny, ſtrait, two-valved beak. There are 17 ſpecies of this inſect. Many of them wound in a very painful manner, and are particularly troubleſome to cattle in low meadows; others of them are quite harmleſs.

ASLANI, in commerce, is a ſilver coin, worth from 115 to 120 aſpers, and is ſynonymous with Aſper.

ASMODAI, or Asmodeus, was a name given by the Jews to the prince of demons; which, according to ſome, is the ſame with Sammael.

ASMOTUS, in ichthyology, is a ſpecies of the Silenus.

ASORE, or Asker, in zoology, is a ſynonyme of the water newt or eft.

ASP, in natural hiſtory, a ſmall poiſonous kind of ſerpent, whoſe bite gives a ſpeedy but eaſy death. It is ſaid to be thus denominated from the Greek ασπις, *ſhield*, in regard to the manner of its lying convolved in a circle, in the centre of which is the head, which it exerts, or raiſes, like the umbo or umbilicus of a buckler.

This ſpecies of ſerpent is frequently mentioned by authors; but ſo diffuſely deſcribed, that it is not eaſy to determine which of the ſpecies known at preſent may properly be called by this name. It is ſaid to be common in Africa, and on the banks of the Nile.

It is with the aſp that Cleopatra is ſaid to have diſpatched herſelf, and prevented the deſigns of Auguſtus, who intended to have carried her captive to adorn his triumphal entry into Rome. However, the fact is conteſted; which Brown places among vulgar errors.

The indications of that queen's having uſed the miniſtry of the aſp, were only two almoſt inſenſible pricks found in her arm; and Plutarch ſays it is unknown what ſhe died of. At the ſame time, it muſt be obſerved, that the ſlightneſs of the pricks found in her arm furniſhes no preſumption againſt the fact; for no more than the prick of a needle-point dipt in the poiſon was neceſſary for the purpoſe.

Lord Bacon deſcribes the bite of the aſp as the leaſt painful of all the inſtruments of death. He ſuppoſes it to have an affinity to opium, but to be leſs diſagreeable in its operation; which opinion ſeems to correſpond with the accounts of the beſt writers, as well as with the effects deſcribed to have been produced upon Cleopatra.

The ancients had a plaſter called δι Ασπιδων, made of this terrible animal, of great efficacy as a diſcutient of ſtrumæ and other indurations, and uſed likewiſe againſt pains of the gout.

The fleſh and ſkin, or exuviæ, of this creature, had alſo their ſhare in the ancient materia medica.

ASPALATHUS, African Broom, in botany, is a genus of the decandria order, belonging to the diadelphia claſs of plants; and in the natural method ranking under the 32d order, Papilionaceæ.

The calyx conſiſts of 5 diviſions; the pod is oval, and contains 2 ſeeds.

There are 19 ſpecies; all of which are natives of warm climates, and muſt be preſerved in ſtoves by thoſe who would cultivate them here.

The roſe-wood is one of the ſpecies, but of which we have yet had no particular deſcription.

It was anciently in much repute as an aſtringent, ſtrengthener, and drier; but it is now diſuſed in internal practice. It affords an oil of an admirable ſcent, reputed one of the beſt perfumes: it is chiefly uſed in ſcenting pomatums and liniments.

ASPARAGUS, Sparagus, Sperage, or Sparrowgrass, in botany, is a genus of the monogynia order, belonging to the hexandria claſs of plants; and in the natural method ranking under the 11th order, Sarmentaceæ.

The calyx is quinquepartite, and erect; the three inferior petals are bent outwards; the berry has three cells, and contains two ſeeds.

There are 10 ſpecies, but the only one cultivated in the gardens is that with an upright herbaceous ſtalk, briſtly leaves, and equal ſtipula, or the common aſparagus. The other ſpecies are kept in the gardens of the curious for the ſake of variety.

The garden aſparagus is with great care cultivated for the uſe of the table. The propagation of this uſeful plant is from ſeed; which muſt be ſown about the beginning of February in a bed of rich earth. They muſt not be ſown too thick, and trod into the ground, the earth raked over them ſmooth: the bed is to be kept clear of weeds all the ſummer; and in October, when the ſtalks are withered and dry, a little rotten dung muſt be ſpread half an inch thick over the whole ſurface of the bed. The ſpring following, the plants will be fit to plant out for uſe; the ground muſt therefore be prepared for them by trenching it well, and burying a large quantity of rotten dung in the trenches, ſo that it may lie at leaſt ſix inches below the ſurface of the ground: when this is done, level the whole plot exactly, taking out all the looſe ſtones. This is to be done juſt at the time when the aſparagus is to be planted out; which muſt be in the beginning of March, if the ſoil is dry and the ſeaſon forward; but in a wet ſoil, it is better to wait till the beginning of April, which is about the ſeaſon that the plants are beginning to ſhoot.

The ſeaſon being come, the roots muſt be carefully taken up with a narrow pronged dung fork, ſhaking them out of the earth, ſeparating them from each other, and obſerving to lay all their heads even, for the more convenient planting them.

Between every four rows a ſpace of two feet and a half ſhould be left for walking in, to cut the aſparagus. When the aſparagus is thus planted, a crop of onions may be ſown on the ground, which will not at all hurt it. A month after this, the aſparagus will come up, when the crop of onions muſt be thinned, and the weeds carefully cleared away. About Auguſt the onions will be fit to fill up.

In October following, cut off the ſhoots of the aſparagus within two inches of the ground, clear well all weeds away, and throw up the earth upon the beds, ſo as to leave them five inches above the level of the alleys. A row of colworts may be planted in the middle of the alleys, but nothing muſt be now ſown on the beds. In the ſpring the weeds muſt be howed up, and all the ſummer the beds kept clear of weeds.

In October they muſt be turned, and earthed again, as the preceding ſeaſon. The ſecond ſpring after planting, ſome of the young aſparagus may be cut for the table. The larger ſhoots ſhould only be taken, and theſe ſhould be cut at two inches under ground, and the beds every year managed as in the ſecond year.

The roots have a bitteriſh mucilaginous taſte, inclining to ſweetneſs; the fruit has much the ſame kind of taſte; the young ſhoots are more agreeable than either. Aſparagus promotes appetite, but affords little nouriſhment. It gives a ſtrong ill ſmell to the urine in a little time after eating it, and for this reaſon chiefly is ſuppoſed to be diuretic: it is likewiſe eſteemed aperient and deobſtruent; the root is one of the five called opening roots.

Aſparagus appears from experience to contribute very little either to the exciting of urine when ſuppreſſed, or increaſing its diſcharge; and in caſes where aperient medicines generally do ſervice, this has little or no effect.

Aspacia, among ancient phyſicians implies a conſtrictive medicine for the *prudenda muliebria*. It conſiſted only of wool, moiſtened with an infuſion of unripe galls.

ASPATICUM, in eccleſiaſtical hiſtory, was a place, or apartment, adjoining to the ancient churches, in which the biſhop and preſbyters ſat, to receive the ſalutations of the perſons who came to viſit them, deſire their bleſſing, or conſult them on buſineſs.

This was alſo called *aſpaticum*, *diaconicum*, *roceptorium*, *metatorium*, or *meſatorium*, and *ſalutatorium*; in Engliſh, greeting-houſe.

ASPECT, in aſtronomy, denotes the ſituation of the planets and ſtars with reſpect to each other.

There are five different aſpects. 1. Sextile aſpect is when the planets or ſtars are 60° diſtant, and marked thus *. 2. The quartile, or quadrate, when they are 90° diſtant, marked □. 3. Trine, when 120° diſtant, marked △. 4. Oppoſition, when 180° diſtant, marked ☍. And, 5. Conjunction, when both in the ſame degree, marked ☌.

It is to be obſerved, that theſe aſpects being firſt introduced by aſtrologers, were diſtinguiſhed into benign, malignant, and indifferent; the quartile and oppoſition being accounted malign; the trine and ſextile, benign or friendly; and the conjunction, indifferent.

ASPEN Tree, in botany, is the ſame as Populus.

ASPER, in grammar, ſignifies an accent peculiar to the Greek language, marked thus (ʽ); and importing, that the letters over which it is placed ought to be ſtrongly aſpirated, or pronounced, as if an *h* were joined with them.

Asper, or *Aſpre*, in commerce, is a Turkiſh coin, three of which make a medine.

ASPERA Arteria, in anatomy, is the ſame with the wind-pipe or trachea.

ASPERIFOLIATE, or Asperifolious, among botaniſts, imply ſuch plants as have rough leaves placed alternately on their ſtalks, and a monopetalous flower divided into five parts.

They conſtitute an order of plants in the *Fragmenta methodi naturalis* of Linnæus, in which are theſe genera, viz. tournefortia, cerinthe, ſymphytum, pulmonaria, anchuſa, lithoſpermum, myoſotis, heliotropium, cynogloſſum, aſperugo, lycopſis, echium, borrago: *magis minuſve oleraceæ, mucilaginoſæ, & glutinoſæ ſunt.* Lin.

In the preſent ſyſtem of nature theſe are among the pentandria monogynia.

ASPERIFOLIÆ Plantæ, in botany, are rough leaved plants. The name of a claſs in Hermanus, Boerhaave, and Ray's methods, conſiſting of plants which have four naked ſeeds, and whoſe leaves are rough to the touch.

In Tournefort's Syſtem, theſe plants conſtitute the third ſection or order of the ſecond claſs; and in Linnæus's Sexual Method, they make a part of the pentandria monogynia.

ASPERITY, implies the inequality of the ſurface of any body, which hinders the hand from paſſing over it freely. From the teſtimony of ſome blind perſons, it has been ſuppoſed that every colour hath its particular degree of aſperity.

ASPERSION, ſignifies the act of ſprinkling with ſome liquid ſubſtance. Hence in the ceremonial of baptiſm ſome contend for aſperſion, whilſt others as ſtrenuouſly oppoſe them, and declare for immerſion.

ASPERUGO, small wild buglos, in botany, is a genus of the petandria monogynia claſs; and in the natural method ranking under the 49th order, Aſperifoliæ.

The calyx of the fruit is compreſſed with folds flatly parallel, and ſinuous.

There are two ſpecies, viz. the procumbens, or wild buglos, a native of Britain; and the Egyptiaca, a native of Egypt.

ASPERULA, Asperjula, or Woodroof, in botany, a genus of the monogynia order, belonging to the hexandria claſs of plants; and in the natural method ranking under the 47th order, Stellatæ.

The corolla is infundibuliform; and the capſule contains two globular ſeeds.

There are two ſpecies, viz. the cynanchia and the odorata. Both of them grow wild in Britain, ſo are ſeldom admitted into gardens. The fruit is found on chalky hills. The latter in woods and copſes, and flowering in May. It has an exceeding pleaſant ſmell, which is improved by moderate exſiccation; the taſte is ſubſaline, and ſomewhat auſtere. It imparts its flavour to vinous liquors.

Aſperula is ſuppoſed to attenuate viſcid humours, and ſtrengthen the tone of the bowels; it is recommended in obſtructions of the liver and biliary ducts, and by ſome in epilepſies and palſies.

The ſmell of it is ſaid to drive away ticks and other inſects. The roots of the firſt are uſed in Sweden to dye red.

ASPHALITES, in anatomy, ſignifies the 5th vertebra of the loins, being ſo called from its ſituation, as it is conceived to ſupport the whole ſpine of the loins.

The wood is compounded of the privative α, and σφαλλω, I ſupplant.

ASPHALTUM, Bitumen Judaicum, or Jews Pitch, in foſſilogy, is a light ſolid bitumen, of a duſky colour on the outſide, and a deep ſhining black within; of very inſipid taſte; having ſcarcely any ſmell, unleſs heated, when it emits a ſtrong pitchy one. It is found in a ſoft or liquid ſtate on the ſurface of the Dead Sea, and by age grows dry and hard.

The ſame kind of bitumen is found in the earth, in other parts of the world, viz. in China, America, and in ſome parts of Europe, as the Carpathian hills, France, Neuſchatel, &c.

ASPHODELUS, Asphodel, or King's Spear, in botany, is a genus of the monogynia order, belonging to the hexandria claſs of plants. The calyx is divided into ſix parts; and the nectarium conſiſts of ſix valves covering the nectarium.

There are five ſpecies, viz.

1. The luteus, or common yellow aſphodel, hath roots compoſed of many thick fleſhy fibres, which are yellow, and joined into a head at the top; from whence ariſe ſtrong round ſingle ſtalks near three feet high, garniſhed on the upper part with yellow ſtar ſhaped flowers, which appear in June, and the ſeeds ripen in autumn.

2. The ramoſus, or branching aſphodel, hath roots compoſed of fleſhy fibres, to each of which is faſtened on oblong bulb as large as a ſmall potatoe; the leaves are long and flexible, having ſharp edges; between theſe come out the flower ſtalks, which ariſe more than three high, ſending forth many lateral branches. The upper parts of theſe are adorned with white ſtar ſhaped flowers, which grow in long ſpikes flowering gradually upward.

3. The ramoſus, or unbranched aſphodel, hath roots like the ſecond, but the leaves are longer and narrower; the ſtalks are ſingle, never putting out in any ſide branches.

4. The albus, with keel ſhaped leaves, hath roots compoſed of ſmaller fibres than the two laſt, nor are the knobs at bottom half ſo large; the leaves are long, almoſt triangular, and hollow like the keel of a boat.

5. The ſtuloſus, or annual branching ſpiderwort, hath roots compoſed of many yellow fleſhy fibres: the leaves are ſpread out from the crown of the root, cloſe to the ground, in a large cluſter; theſe are convex on their under ſize, but plain above. They produce white ſtarry flowers, with purple lines on the outſide.

The way to increaſe theſe plants is by parting their roots in Auguſt. They may be raiſed from ſeeds ſown in Auguſt, and will produce flowers the ſecond year.

ASPHURELATA, in natural hiſtory, are ſemimetallic foſſils, fuſible by fire, and not malleable in their pureſt ſtate, being in their native ſtate compounded with ſulphur and other adventitious matter, ſo that they are reduced to what are called ores.

Of this ſeries of foſſils there are only five bodies, each of which makes a diſtinct genus, viz. anatomy, biſmuth, cobalt, zinc, and quickſilver.

ASPIRATE, in grammar, denotes words marked with the ſpiritus aſper.

ASPIRATION, among grammarians, is uſed to denote the pronouncing a ſyllable with ſome vehemence.

ASPLENIUM, Ceterach, a genus of the order of filices, belonging to the cryptogamia claſs of plants. The parts of fructification are ſituated in the ſmall ſparſe line under the diſk of the leaves. There are 24 ſpecies; the two moſt remarkable of which, and the only ones worth noticing, are natives of Great Britain, and grow upon old walls or moiſt rocks; one is called ſcolopendrium, or hart's-tongue; the other is, properly, ceterach, alſo called ſpleenwort. It has an herbaceous, ſomewhat mucilaginous, roughiſh taſte: it is recommended as a pectoral, and for promoting urine in nephritic caſes.

ASS, in zoology, is ranked as a ſpecies of equus, or the horſe.

Coronation of the Ass, in antiquity, was a part of the ceremony of the feaſt of Veſta, wherein the bakers put bread crowns on the heads of theſe quadrupeds. This honour, it ſeems, was done the beaſt, becauſe, by its braying, it had ſaved Veſta from being raviſhed by the Lampſacan god. Hence the formula, *Veſtæ delicium eſt aſinus.*

ASSAI, in muſic, according to ſome, ſignifies quick; and, to others, that the motion of the piece be kept in a middle degree of quickneſs or ſlowneſs.

ASSARIUM, in antiquity, denotes a ſmall copper coin, being a part or diminutive of the *as.* We find mention of the aſtarion in the goſpel of St. Matthew, chap. x. verſe 29.

ASSARON, or Omer, a meaſure of capacity, anciently in uſe among the Hebrews, containing five pints. It was the meaſure of manna which God appointed for every Iſraelite.

ASSASIN, or Assassin, a perſon who kills another with the advantage either of an inequality in the weapons, or by means of the ſituation of the place, or by attacking him at unawares.

The word aſſaſſin is ſaid by ſome to have been brought from the Levant, where it took its riſe from a certain prince of the family of the Arſacidæ; popularly called aſſaſſins, living in a caſtle between Antioch and Damaſco, and bringing up a number of young men, ready to pay a blind obedience to his commands; whom he employed in murdering the princes with whom he was at enmity But, according to Mr. Volney, the word Haſſaſſin, (from the root haſs, "to kill, to aſſaſſinate, to liſten, to ſurpriſe,") in the vulgar Arabic, ſignifies "Robbers of the night", perſons who lie in ambuſh to kill the unwary, and plunder them of their property.

ASSASSINS, a tribe or clan in Syria, called alſo Iſmaelians and Bataniſts or Batenians. Theſe people probably owed their origin to the Karmatians, a famous heretical ſect among the Mahometans, who ſettled in Perſia about the year 1090; whence, in proceſs of time, they ſent a colony into Syria, where they became poſſeſſed of a conſiderable track of land among the mountains of Lebanon, extending itſelf from the neighbourhood of Antioch to Damaſcus.

Moſt ſovereigns paid ſecretly a penſion to the ſcheik, however ſcandalous and derogatory it might be to the luſtre of majeſty, for the ſafety of their perſons.

Theſe people reigned a long time in Perſia, and on Mount Lebanon. Hulaku, a khan of the Mogul Tartars, in the year 655 of the Hegira, or 1254 of the Chriſtian æra, entered their country and diſpoſſeſſed them of ſeveral places; but it was not till the year 1272 that they were totally conquered. This atchievement was owing to the conduct and intrepidity of the Egyptian forces ſent againſt them by the ſultan Bibaris. It has, however, been thought that the Druſes, who ſtill reſide among the eminences of Mount Lebanon, and whoſe religion and cuſtoms are ſo little known, are a remnant of thoſe barbarians.

ASSAULT, in law, is an attempt or offer to beat another, without touching him: as if one lifts up his cane or his fiſt in a threatening manner at another; or ſtrikes at him, but miſſes him; this is an aſſault, *inſultus*, which Finch deſcribes to be "an unlawful ſetting upon one's perſon." This alſo is an inchoate violence, amounting conſiderably higher than bare threats; and, therefore, though no actual ſuffering is proved, yet the party injured may have redreſs by action of treſpaſs, *vi et armis*, wherein he may recover damages as a compenſation for the injury.

Assault, in the military art, a furious effort made to carry a fortified poſt, camp, or fortreſs, wherein the aſſailants do not ſcreen themſelves by any works: while the aſſault continues, the batteries ceaſe, for fear of killing their own men.

ASSAY, Essay, or Say, in metallurgy, the proof or trial of the goodneſs, purity, value, &c. of metals and metalline ſubſtances. The method ſtill in uſe, of aſſaying gold and ſilver, was firſt eſtabliſhed by an act of the Engliſh parliament 1354.

Assaying, *ars docimaſtica*, in its extent, comprehends particular manners of examining every ore, or mixed metal, according to its nature, with the beſt adapted fluxes; ſo as to diſcover, not only what metals, and what proportions of metal, are contained in ores; but likewiſe how much ſulphur, vitriol, allum, arſenic, ſmelt, &c. may be obtained from every one reſpectively.

Aſſaying is more particularly uſed by moneyers and goldſmiths, for the making a proof or trial by the cuppel, or teſt, of the fineneſs or purity of the gold and ſilver to be uſed in the coining of money, and manufacture of plate, &c. or that have been already uſed therein.

There are two kinds of aſſaying; the one before metals are melted, in order to bring them to their proper fineneſs; the other after they are ſtruck, to ſee that the ſpecies be ſtandard. For the firſt aſſay, the aſſayers take 14 or 15 grains of gold, and half a drachm of ſilver, if it be for money; and 18 grains of the one, and a drachm of the other, if for other occaſions.

As to the ſecond aſſay, it is made of one of the pieces of money already coined, which they cut in four parts. The quantity of gold for an aſſay, among us, is ſix grains; in France, nearly the ſame; and in Germany, about three times as much.

Assay *Balance*, or *Eſſay Balance*, the flat pieces of glaſs often placed under the ſcales of an aſſay-balance, which ſeem, by their power of electricity, capable of attracting, and thereby making the lighter ſcale preponderate, where the whole matter weighed is ſo very ſmall.

The electricity of a flat ſurface, of about three inches ſquare, has been known to hold down one ſcale, when there were about 200 grains weight in the other.

Assay *Maſter* or *Eſſay-Maſter*, an officer under certain corporations entruſted with the care of making true touch, or aſſay, of the gold and ſilver brought to him; and giving a juſt report of the goodneſs or badneſs thereof. Such is the aſſay-maſter of the mint in the Tower, called alſo aſſayer of the king.

The aſſay-maſter of the goldſmiths company, is a ſort of aſſiſtant warden, called alſo a touch-warden, appointed to ſurvey, aſſay, and mark all the ſilver-work, &c. committed to him.

There are alſo aſſay-maſters appointed by ſtatute, at York, Exeter, Briſtol, Cheſter, Norwich, Newcaſtle, and Birmingham, for aſſaying wrought plate. The aſſay-maſter is to retain eight grains of every pound Troy of ſilver brought to him; four whereof are to be put in the pix, or box of deal, to be re-aſſayed the next year, and the other four to be allowed him for his waſte and ſpillings.

Note, The number of pennyweights ſet down in the aſſay-maſter's report, is to be accounted as per pound, or ſo much in every pound of 12 ounces Troy. For every 20 pennyweight, or ounce Troy, the ſilver is found by the aſſay to be worſe than ſtandard, or ſterling, ſixpence is to be deducted; becauſe every ounce will coſt ſo much to reduce it to ſtandard goodneſs, or to change it for ſterling.

In gold, for every carat it is ſet down to be worſe than ſtandard, you muſt account that in the ounce Troy it is worſe by ſo many times 3s. 8d.; and for every grain it is ſet down worſe, you muſt account it worſe by ſo many times 11d. in the ounce Troy; and for every half grain 5½d.: for ſo much it will coſt to make it of ſtandard goodneſs, &c.

ASSEMBLAGE, the uniting or joining of things together; or the things themſelves ſo united or joined. It is alſo uſed, in a more general ſenſe, for a collection of various things ſo diſpoſed and diverſified, that the whole produces ſome agreeable effect.

ASSEMBLY, the meeting of ſeveral perſons, in the ſame place, upon the ſame occaſion.

Assembly, in the beau monde, an appointed meeting of faſhionable perſons of both ſexes, for the ſake of play, dancing, gallantry, converſation, &c.

Assembly, in the military art, the ſecond beating of a drum before a march; at which the ſoldiers ſtrike their tents, roll them up, and ſtand to arms.

Assemblies of the clergy are called convocations, ſynods, councils. The annual meeting of the church of Scotland is called a General Aſſembly: in this aſſembly His Majeſty is repreſented by his commiſſioner, who diſſolves one meeting, and calls another, in the name of the King, while the moderator does the ſame in the name of the Lord Jeſus Chriſt.

Assemblies of the ſtates of kingdoms are called parliaments; ſuch as thoſe of Great Britain, France, Sweden and Poland.

ASSENT, in a general ſenſe, implies an agreement to ſomething propoſed or affirmed by another.

Royal Assent, the approbation given by the king to a bill in parliament, after which it becomes a law.

ASSERTION, in the language of the ſchools, a propoſition advanced by the aſſertor, who avows the truth of it, and is ready to defend it.

ASSESSOR, an inferior officer of juſtice, appointed chiefly to aſſiſt the ordinary judge with his opinion and advice.

Assessor, is alſo one who aſſeſſes, or ſettles taxes and other public dues.

ASSETS, in law, ſignifies goods enough to diſcharge that burthen which is caſt upon the executor or heir, in ſatisfying the debts and legacies of the teſtator or anceſtor. Aſſets are real or perſonal. Where a man hath lands in fee ſimple, and dies ſeiſed thereof, the lands which come to his heir are aſſets real; and where he dies poſſeſſed of any perſonal eſtate, the goods which come to the executors are aſſets perſonal.

Aſſets are alſo divided into aſſets per deſcent, and aſſets inter maines. Aſſets by deſcent is where a perſon is bound in an obligation, and dies ſeiſed of lands which deſcend to the heir, the land ſhall be aſſets, and the heir ſhall be charged as far as the land to him deſcended will extend. Aſſets inter maines, is when a man indebted makes executors, and leaves them ſufficient to pay his debts and legacies; or where ſome commodity or profit ariſeth to them in the right of the teſtator, which are called aſſets in their hands.

ASSEVERATION, a poſitive and vehement affirmation of ſomething.

ASSIDENT Signs, in medicine, are ſymptoms which uſually attend a diſeaſe, but not always; hence differing from pathognomic ſigns, which are inſeparable from the diſeaſe: e. gr. In the pleuriſy, a pungent pain in the ſide; in an acute fever, difficulty of breathing, &c. collectively taken, are pathognomic ſigns; but that the pain extends to the hypochondrium or clavicle, or that the patient lies with more eaſe on one ſide than on the other, are aſſident ſigns.

ASSIDUUS, or Adsiduus, among the Romans, denoted a rich or wealthy perſon.

ASSIENTO, a Spaniſh word ſignifying a farm, in commerce, is uſed for a bargain between the king of Spain and other powers, for importing negroes into the Spaniſh dominions in America, and particularly to Buenos Ayres. The firſt aſſiento was made with the French Guinea company; and, by the treaty of Utrecht, transferred to the Engliſh, who were to furniſh 4800 negroes annually.

ASSIGN, in common law, a perſon to whom a thing is aſſigned or made over.

ASSIGNATION, an appointment to meet. The word is generally underſtood of love-meetings.

ASSIGNEE, in law, a perſon appointed by another to do an act, tranſact ſome buſineſs, or enjoy a particular commodity.

ASSIGNING, in a general ſenſe, implies making over the right of one perſon to another. In a particular ſenſe, it ſignifies pointing out ſomething; as, an error, falſe judgment, or waſte.

ASSIGNMENT, transferring the intereſt one has in a leaſe, or other thing, to another perſon.

ASSIMILATION, in phyſics, is that motion by which bodies convert other bodies related to them, or at leaſt ſuch as are prepared to be converted, into their own ſubſtance and nature. Thus, flame multiplies itſelf upon oily bodies, and generates new flame; air upon water, and produces new air; and all the parts, as well ſimilar as organical, in vegetables and animals, firſt attrack with ſome election or choice, nearly the ſame common or not very different juices for aliment, and afterwards aſſimilate or convert them to their own nature.

ASSINARII, in heathen Rome, was a name given to both Jews and Chriſtians by the Pagans, intimating that they might with equal propriety worſhip an aſs, as a deity they could neither hear, ſee, or converſe with.

ASSISE, in old Engliſh law-books, is defined to be an aſſembly of knights, and other ſubſtantial men, together with a juſtice, in a certain place, and at a certain time: but the word, in its preſent acceptation, implies a court, place, or time, when and where the writs and proceſſes, whether civil or criminal, are decided by judge and jury.

The counties of England are divided into ſix circuits; and two judges are aſſigned by the king's commiſſion, who hold their aſſiſes twice a-year in every county, except London and Middleſex, where courts of *niſi prius* are holden in and after every term, before the chief or other judge of the ſeveral ſuperior courts; and except the four northern counties, where the aſſiſes are taken only once a-year, to try by a jury of the reſpective counties the truth of ſuch matters of fact as are then under diſpute in the courts of Weſtminſter Hall.

The judges upon their circuits ſit by virtue of five ſeveral authorities. 1. The commiſſion of the peace, in every county of the circuits; and all juſtices of the peace of the county are bound to be preſent at the aſſiſes; and ſheriffs are alſo to give their attendance on the judges, or they ſhall be fined. 2. A commiſſion of oyer and terminer, directed to them and many other gentlemen of the county, by which they are empowered to try treaſons, felonies, &c. and this is the largeſt commiſſion they have. 3. A commiſſion of general gaol-delivery, directed to the judges and the clerk of aſſiſe aſſociate, which gives them power to try every priſoner in the gaol committed for any offence whatſoever, but none but priſoners in the gaol; ſo that one way or other they rid the gaol of all the priſoners in it. 4. A commiſſion of aſſiſe, directed to the judges and clerk of aſſiſe, to take aſſiſes; that is, to take the verdict of a peculiar ſpecies of jury called an aſſiſe, and ſummoned for the trial of landed diſputes. The other authority is, 5. That of *niſi prius*, which is a conſequence of the commiſſion of aſſiſe, being annexed to the office of thoſe juſtices by the ſtatute of Weſtm. 2. 13 Edw. I. c. 30. And it empowers them to try all queſtions of fact iſſuing out of the courts of Weſtminſter, that are then ripe for trial by jury.

ASSOCIATION, the act of aſſociating, or conſtituting a ſociety, or partnerſhip, in order to carry on ſome ſcheme or affair with more advantage.

Association *of Ideas*, is where two or more ideas conſtantly and immediately follow or ſucceed one another in the mind, ſo that one ſhall almoſt infallibly produce the other whether there be any natural relation between them or not.

ASSOILZIE, in law, to abſolve or free.

ASSONANCE, in rhetoric and poetry, a term uſed where the words of a phraſe or a verſe have the ſame ſound or termination, and yet make no proper rhyme.

ASSUMPSIT, in the law of England, a voluntary or verbal promiſe, whereby a perſon aſſumes, or takes upon him to perform or pay any thing to another.

ASSUMPTION, a feſtival in the Romiſh church, in honour of the miraculous aſcent of the Virgin Mary into heaven: the Greek church, who alſo obſerve this feſtival, celebrate it on the 15th of Auguſt with great ceremony.

Assumption, in logic, is the minor or ſecond propoſition in a categorical ſyllogiſm.

Assumption is alſo uſed for a conſequence drawn from the the propoſitions whereof an argument is compoſed.

ASSUMPTIVE Arms, in heraldry, are ſuch as a perſon has a right to aſſume, with the approbation of his ſovereign, and of the heralds: thus, if a perſon, who has no right by blood, and has no coat of arms, ſhall captivate, in any lawful war, any gentleman, nobleman, or prince, he is, in that caſe, intitled to bear the ſhield of that priſoner, and enjoy it to him and his heirs for ever.

ASSUROR, a merchant, or other perſon, who makes out a policy of aſſurance, and thereby inſures a ſhip, houſe, or the like.

ASTANDA, in antiquity, a royal courier or meſſenger.

ASTARTE, in Pagan mythology, a Phœnician goddeſs, called the queen of heaven, and the goddeſs of the Sidonians.

ASTER, Star-wort, a genus of the polygamia ſuperflua order, belonging to the ſyngeneſia claſs of plants; and in the natural method ranking under the 49th order, Compoſitæ diſcoides. The receptacle is naked; the pappus is ſimple; the rays of the corolla are 10; and the calyx is imbricated. There are above 30 ſpecies, all of which may be raiſed from ſeed ſown either in autumn or ſpring: but the greateſt part being perennial plants, and increaſing greatly at the roots, are generally propagated by parting their roots early in the ſpring, and they will grow in almoſt any ſoil or ſituation; and the larger ſorts increaſe ſo faſt, that, if not prevented, they will in a little time run over a large ſpace of ground. They grow beſt in the ſhade: the lower kinds do not run ſo much at the root, but ſhould be taken up and tranſplanted every other year; which will make them produce much fairer flowers. Some few ſorts, which are natives of warm climates, will require artificial heat to raiſe them, if not to preſerve them.

ASTERIA, in zoology, a name by which ſome authors have called the *falco palumbarius*, or *goſhawk*.

Asteria is alſo the name of a gem, uſually called the *cat's eye*, or *oculus cati*. It is a very ſingular and very beautiful ſtone, and ſomewhat approaches to the nature of the opal, in having a bright included colour, which ſeems to be lodged deep in the body of the ſtone, and ſhifts about, as it is moved, in various directions: but it differs from the opal in all other particulars, eſpecially in its want of the great variety of colours ſeen in that gem, and in its ſuperior hardneſs. It is uſually found between the ſize of a pea and the breadth of a ſixpence; is almoſt always of a ſemicircular form, broad and flat at the bottom, and rounded and convex at the top; and is naturally ſmooth and poliſhed. It has only two colours, a pale brown and a white; the brown ſeeming the ground, and the white playing about in it, as the fire colour in the opal. It is conſiderably hard, and will take a fine poliſh, but is uſually worn with its native ſhape and ſmoothneſs. It is found in the Eaſt and Weſt Indies, and in different parts of Europe.

Asteria is alſo the name of an extraneous foſſil, called in Engliſh the *ſtar-ſtone*. Theſe foſſils are ſmall, ſhort, angular, or ſulcated columns, between one and two inches long, and ſeldom above a third of an inch in diameter: compoſed of ſeveral regular joints; when ſeparated, each reſembles a radiated ſtar. They are, not without reaſon, ſuppoſed to be a part of ſome ſea-fiſh petrified, probably the aſterias or ſea-ſtar. The aſteria is alſo called aſtrites, aſtroites, and aſteriſcus. They may be reduced to two kinds: thoſe whoſe whole bodies make the form of a ſtar; and thoſe which in the whole are irregular, but adorned as it were with conſtellations in the parts. The curious frequently meet with theſe ſtones in many parts of England, particularly at Cleydon in Oxfordſhire.

ASTERIAS, Star-fish, or Sea-star, in zoology, a genus of the order of vermes molluſca. It has a depreſſed body, covered with a coriaceous coat; is compoſed of five or more ſegments, running out from a central part, furniſhed with numerous tentacula; and has the mouth in the centre.

Among the various ſpecies of the aſterias, the following are found in the Britiſh ſeas. 1. The glacialis, with five rays, depreſſed, broad at the baſe, yellow, and having a round ſtriated operculum on the back, is the moſt common; it feeds on oyſters, and is very deſtructive to the beds. 2. The clathatra, or cancellated ſea-ſtar, with five ſhort thick rays, hirſute beneath, cancellated above, is found with the former, but more rare. 3. The oculata, with five ſmooth rays, dotted or punctured, is of a fine purple colour, and is found about Angleſea. 4. The hiſpida, with five rays, broad, angulated at top, and rough with ſhort briſtles, is of a brown colour, and likewiſe found about Angleſea. 5. The placenta, with five very broad and membranaceous rays, extremely thin and flat, is found about Weymouth. 6. The ſpherulata, with a pentagonal indented body; a ſmall globular bead between the baſe of each ray; the rays ſlender, jointed, taper, and hirſute on their ſides; found off Angleſea. 7. The caput meduſæ, or arboreſcent ſea-ſtar, with five rays iſſuing from an angular body; the rays dividing into innumerable branches, growing ſlender as they recede from the baſe. Theſe the animal, in ſwimming, ſpreads like a net to their full length; and when he perceives any prey within them, draws them in again, thus catching it with all the dexterity of a fiſherman. It is an inhabitant of every ſea; and is called by ſome the *Magellanic ſtar-fiſh* and *baſket fiſh*. When it extends its rays fully, it forms a circle of near three feet in diameter. The fragments of theſe rays furniſh the foſſile entrochi. There are ſeveral other ſpecies mentioned by authors; ſome of them 10, 12, 13, or even 14 rays.

Asterias likewiſe ſignifies the ancient name of the bittern.

ASTERISK, a mark in form of a ſtar (*), placed over a word or ſentence, to refer the reader to the margin, or elſewhere, for a quotation, explanation, or the like.

ASTERN, a ſea-phraſe, uſed to ſignify any thing at ſome diſtance behind the ſhip.

ASTEROPODIUM, a kind of extraneous foſſil, of the ſame ſubſtance with the aſteriæ or ſtar-ſtones, to which they ſerve as a baſe.

ASTRAL, that which belongs, or relates to the ſtars. Aſtral year, is the time the earth takes to make its revolution round the ſun.

ASTRÆA, in aſtronomy, a name which ſome give to the ſign Virgo, by others called Erigone, and ſometimes Iſis.

ASTRAGAL, in architecture, a little round moulding, which in the orders ſurrounds the top of the ſhaft or body of the column. It is alſo called the talon and tondino; it is uſed at the bottoms as well as tops of columns, and on other occaſions; it properly repreſents a ring, on whatever part of a column it is placed. It is often cut into beads and berries, and is uſed in the ornamented entablatures to ſeparate the ſeveral faces of the architrave.

Astragal, in gunnery, a round moulding, encompaſſing a cannon, about half a foot from its mouth.

ASTRAGALUS, Mik-vetch, or Liquorice-vetch, a genus of the decandria order, belonging to the diadelphia claſs of plants; and in the natural method ranking under the 32d order, Papilionaceæ. The pod is gibbous and bilocular. Of this genus there are 39 ſpecies. The common ſort grows wild upon dry uncultivated places, and is recommended by Mr. Anderſon to be cultivated as proper food for cattle. The other ſpecies deſerving notice is the tragagantha, a thorny buſh growing in Crete, Aſia, and Greece, which yields the gum tragacanth. This is of ſo ſtrong a body, that a dram of it will give a pint of water the conſiſtence of a ſyrup, which a whole ounce of gum Arabic is ſcarce ſufficient to do. Hence its uſe for forming troches, and the like purpoſes, in preference to the other gums.

ASTRANTIA, Masterwort, a genus of the dyginia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 45th order, Umbellatæ. The involucrum is lanceolated, open, equal, and coloured. The ſpecies are two, the major and minor, both natives of the Alps, but poſſeſſing no remarkable properties.

Astriction, among phyſicians, denotes the operation of aſtringent medicines.

ASTRINGENTS, in the materia medica, ſubſtances diſtinguiſhed by a rough auſtere taſte, and changing ſolutions of iron, eſpecially thoſe made in the vitriolic acid, into a dark purple or black colour; ſuch are galls, tormentil root, biſtort root, balauſtines, terra japanica, acacia, &c.

ASTROGNOSIA, the ſcience of the fixed ſtars, or the knowledge of their names, conſtellations, magnitudes, &c.

ASTROITES, or Star-stone, in natural hiſtory. See the article Asteria and Star-stone.

ASTROLABE, the name for a ſtereographic projection of the ſphere, either upon the plane of the equator, the eye being ſuppoſed to be in the pole of the world; or upon the plane of the meridian, when the eye is ſuppoſed in the point of the interſection of the equinoctial and horizon.

Astrolabe is alſo the name of an inſtrument formerly uſed for taking the altitude of the ſun or ſtars at ſea.

ASTROLOGY, a conjectural ſcience, which teaches to judge of the effects and influences of the ſtars, and to foretel future events by the ſituation and different aſpects of the heavenly bodies. This ſcience has been divided into two branches, natural and judiciary. To the former belongs the prediction of natural effects; as, the changes of weather, winds, ſtorms, hurricanes, thunder, floods, earthquakes, &c. This art properly belongs to natural philoſophy; and is only to be deduced, *à poſteriori*, from phenomena and obſervations. Judiciary or judicial aſtrology, is that which pretends to foretel moral events; i. e. ſuch as have a dependence on the free will and agency of man; as if they were directed by the ſtars. This art, which owed its origin to the practices of knavery on credulity, is now univerſally exploded by the intelligent part of mankind. The chief province of it that remain to the modern profeſſors, is the making of calendars or almanacks.

Judicial aſtrology is commonly ſaid to have been invented in Chaldea, and thence tranſmitted to the Egyptians, Greeks, and Romans; though ſome will have it of Egyptian origin, and aſcribe the invention to Cham. But it is to the Arabs that we owe it. At Rome the people were ſo infatuated with it, that the aſtrologers, or, as they were then called, the mathematicians, maintained their ground in ſpite of all the edicts of the emperors to expel them out of the city.

The Bramins, who introduced and practiſed this art among the Indians, have hereby made themſelves the arbiters of good and evil hours, which gives them great authority: they are conſulted as oracles; and they have taken care never to ſell their anſwers but at good rates.

The ſame ſuperſtition has prevailed in more modern ages and nations. The French hiſtorians remark, that in the time of queen Catharine de Medicis, aſtrology was in ſo much vogue, that the moſt inconſiderable thing was not to be done without conſulting the ſtars. And in the reigns of king Henry III. and IV. of France, the predictions of aſtrologers were the common theme of the court converſation. This predominant humour in that court was well rallied by Barclay, in his Argenis, lib. ii. on occaſion of an aſtrologer, who had undertaken to inſtruct king Henry in the event of a war then threatened by the fraction of the Guiſes.

ASTRONIUM, in botany, a genus of the pentandria order, belonging to the diœcia claſs of plants. The male calyx conſiſts of five leaves, and the corolla is quinquepetalous; of the female the calyx and corolla are the ſame as in the male; the ſtyli are three, and the ſeed is ſingle. There is but one ſpecies, the graveolens, a native of Jamaica.

ASTRONOMICAL, ſomething relating to Astronomy.

Astronomical *Calender*, an inſtrument engraved on copper plates, printed on paper, and paſted on a board, with a braſs ſlider carrying a hair: it ſhows by inſpection the ſun's meridian altitude, right aſcenſion, declination, riſing, ſetting, amplitude, &c. to a greater degree of exactneſs than the common globes.

ASTRONOMY, ſignifies a knowledge of the heavenly bodies, with regard to their magnitudes, motions, diſtances, &c. real or apparent; and of the natural cauſes whereon; the whole of which the reader will find diſplayed in the Syſtem on this ſubject.

The following Syſtem of Aſtronomy is compiled and arranged by the Rev. T. Bankes, of St. Mary Hall, Oxon, and Vicar of Dixton, in Monmouthſhire, for whoſe liberal contribution to this Work I am conſiderably indebted, for which I return my public acknowledgements.

C. COOKE.

In the following Syſtem I have carefully conſulted the beſt authors, and it has been my ſtudy to expunge every thing that appeared frivolous, and to retain all that is eſſential to the attainment of a competent underſtanding of this Science, as far as the extent of the Work will permit.

To this end, the Reader will find I have given a variety of Problems of the Sphere, with the different modes of projection, and the methods of computation; ſubjects which have been wholly neglected in every work of this kind, even in that voluminous, and expenſive Edition, entitled the "Encyclopædia Britannica," publiſhed in Scotland.

I have alſo ſhewn, how to aſcertain the Elements of the Sun, Moon, and Planets, by Obſervation; and have been particularly attentive to the New Diſcoveries made by that excellent Aſtronomer, Dr. Herſchell.

As for Aſtronomical Tables, for calculating the Planets' Places, Lunations, Eclipſes, &c. there are ſuch perpetual alterations and amendments neceſſary to be made therein, ſo as to adjuſt them to the planetary motions, that I rather choſe to leave the Reader to procure (if wanted) ſuch a ſet as he may judge the moſt correct, than ſacrifice ſo many pages as they would have taken to ſo vague a purpoſe, and to the excluſion of thoſe eſſential articles, which are conſtantly the ſame, and which ſhould not be diſpenſed with.

But indeed the following Syſtem is ſo comprehenſive, that the Reader will be enabled to make Tables for himſelf, provided he is furniſhed with proper obſervations, on which he may found his calculations; and, I truſt, that nothing is omitted which can tend to give a clear, comprehenſive, and practical knowledge in this delightful Science.

T. BANKES.

SYSTEM OF ASTRONOMY.

SECTION I.

HISTORY OF ASTRONOMY.

THAT Aſtronomy was ſtudied in the very firſt ages of the world is beyond a doubt, as it muſt have been a neceſſary reſearch to form ſome judgment of the elapſe of time; for without that there could be no way of communicating ideas of paſt events, much leſs any intelligible records made of them.

And this could only be done by duly obſerving the motions and revolutions of the ſun and moon, which the All-wiſe Creator has appointed as indexes for that purpoſe. From this it ſhould appear that even Adam was not deſtitute of ſome knowledge in Aſtronomy; for, otherwiſe, how could an account of his age at the birth of Seth, or the number of years that he lived, have been preſerved?

Beſides, it ſeems extremely probable, that he, whom the Almighty had made Lord over the Creation, by placing every creature in ſubordination, and to whom he committed the naming of every thing, ſhould know ſomething of the nature of each, and their ſeveral uſes.

Joſephus, however, writes that Seth or his nephews firſt obſerved the order of the heavens, and the courſes of the ſtars; and ſuppoſes that longevity was beſtowed upon the Antediluvians for the very purpoſe of improving the ſciences of Geometry and Aſtronomy; adding, that the latter could not be learned in leſs than 600 years, the extremity of that period being the grand year. It is ſuppoſed Joſephus meant the period in which the ſun and moon came again into the ſame ſituation, with regard to the moons, nodes, apogee, &c. as at the beginning.

If this was a fixed period of the Antediluvians, they muſt have known more of Aſtronomy than was known many ages after the flood.

Among the nations who firſt made any conſiderable figure in hiſtory, the Chaldeans and Egyptians were the moſt remarkable for their Aſtronomical knowledge. They diſputed with each other the honour of having the firſt cultivators of Aſtronomy. The Chaldeans boaſted of their temple of Belus, and of Zoroaſter, who, as they pretended, flouriſhed 5000 years before the deſtruction of Troy; though, it is pretty certain, that he lived within a thouſand years of that event. The Egyptians on the other hand exulted in their ancient colleges of prieſts, where Aſtronomy was taught, and of the monument of Oſymandyas; in which it is ſaid, there was a golden circle of 365 cubits in circumference, and one cubit thick. It is recorded that the upper face was divided into 365 equal parts, correſponding to the days in a year; and that on each diviſion was written the name of the day, the heliacal riſing of the ſeveral ſtars for ſuch day, with prognoſtications, &c.

It is farther ſaid, that the Babylonians had obſervations for 700 years engraven upon bricks; and that when Alexander took Babylon, he carried away obſervations for almoſt 2000 years; but as they fell into the hands of ignorant and careleſs people, the greateſt part of them were loſt; which is ſuch a period of time, and fund of obſervations, as we have not to ſhew at this day. So arts and ſciences, as well as the ſtars, have their periods, ſtations, and retrogradations.

However, according to the beſt accounts, the Chaldeans derived the chief of their knowledge in Aſtronomy from the Egyptians who fled to Babylon, when Egypt was invaded by the Ethiopians.

The riſe of Aſtronomy, among the Greeks, is unknown; though many are of opinion that they, as well as the Phœnicians, derived their knowledge in this ſcience from the Egyptians.

After Aſtronomy was carried into Greece, Thales, the Mileſian, went thither for inſtruction. He flouriſhed about 580 years before Chriſt, and delighting himſelf in the ſcience, made conſiderable improvements. He is ſaid to have obſerved the exact time of the ſolſtices, and equinoctial points, to have taught the obliquity of the ecliptic, and to have been the firſt who foretold eclipſes.

He predicted a total eclipſe of the ſun, which happened on the 28th of May, 585 years before Chriſt, and alſo another of the moon.

After Thales, Anaximander, Anaximanes, Anaxagoras, and Pythagoras, contributed conſiderably to the advancement of Aſtronomy. Pythagoras made great improvements both in Aſtronomy and Geometry, and deſcribed the order of the univerſe agreeable to the preſent Newtonian ſyſtem.

Then followed Philolaus, Hicetas, Meton, Euctemon, Plato, Ariſtotle, Eudoxus, Calippus, &c. all of whom were men of conſiderable renown, and aſſiduous in promoting the progreſs of this and other ſciences; though Plato and Ariſtotle inſtead of advancing, rather clouded Aſtronomy, by embracing an erroneous ſyſtem, which was afterwards rigidly taught by Ptolemy, and from thence it was called the Ptolemaic ſyſtem.

Ariſtarchus, who lived about 270 years before Chriſt, diligently ſtrove to reſcue Aſtronomy from the obſcurity into which it was brought by Plato and Ariſtotle, ſtrenuouſly aſſerting and defending the Pythagorean ſyſtem.

He gave a method of determining the diſtance of the ſun by the moon's dichotomy.

The celebrated Archimedes, about 220 years before Chriſt, was no leſs ſkilful in Aſtronomy than Geometry. He invented a planetarium, or orrery, for repreſenting the phænomena and motions of the heavenly bodies; he alſo determined the diſtance of the moon from the earth, of Mercury from the moon, of Venus from Mercury, of the ſun from Venus, of Mars from the ſun, of Jupiter from Mars, and of Saturn from Jupiter; as likewiſe the diſtance of the fixed ſtars from the orbit of Saturn.

Hipparchus, who flouriſhed about 140 years before Chriſt, was a diligent obſerver of the ſtars. He was the firſt who diſcovered the orbits of the moon and planets to be excentric, and the anticipation of the moon's nodes. He alſo determined the length of the year with great accuracy; conſtructed tables of the motions of the ſun and moon; and gave a catalogue of the latitudes, longitudes, and apparent magnitudes of 1022 ſtars.

In ſhort, he is reputed to have been the firſt who applied his ſtudy to every part of Aſtronomy; and ſo indefatigable was he in his purſuits, that he is ſaid to have calculated all the eclipſes that were to happen for the ſpace of 600 years after his time.

From the time of Hipparchus to that of Ptolemy, who flouriſhed about A. D. 70, Aſtronomy made but little progreſs, and then it became inveloped in miſt and obſcurity, through Ptolemy's reviving the erroneous notions of Plato and Ariſtotle, as was before obſerved.

From this period, till the 16th century, the Pythagorean Syſtem was intirely laid aſide; when it was reſtored again by Nicholaus Copernicus, who wrote a treatiſe dedicated to Pope Paul III. in the preface of which he attempted to apologize as much as poſſible for the extraordinary doctrines it appeared to contain. He died, however, within a few hours of its publication. But although, from the time of Ptolemy to that of Copernicus, the true ſyſtem was exploded, yet there were ſome who in other reſpects improved the ſcience.

Among the Arabians, the Caliph Al Mamun, who aſcended the throne in A. D. 814, was a great encourager of the Sciences. He made many aſtronomical obſervations himſelf, and determined the obliquity of the ecliptic to be 23° 35′. Alſo Albategnius, about A. D. 880, greatly reformed Aſtronomy, he determined the preceſſion of the Equinoxes to be 1 degree in 70 years, and with Al Mamun fixed the Sun's greateſt declination, at 23° 35′.

Uleg Beg, grandſon of the famous Tamerlane, was a great proficient in practical Aſtronomy. He compoſed Aſtronomical Tables from his own obſervations ſo exact as to differ very little from thoſe afterwards conſtructed by Tycho Brache. He alſo gave a Catalogue of the fixed Stars made from his own obſervations in A. D. 1437; and determined the latitude of Samarcand, his capital, to be 39° 37′ 23″. This ſhews how accurate he was in his obſervations. Likewiſe, previous to the time of Copernicus, John De Sacro Boſco (an Engliſhman), Purbach, John Muller of Monteregio, in Franconia, generally named Regiomontanus, and John Werner, a clergyman, at Nuremberg, were great ſtudents in aſtronomy. The laſt of whom determined the preceſſion of the equinoctial points to be 1 degree and 10 minutes in 100 years; and the obliquity of the ecliptic to be 23° 28′, which numbers nearly agree with modern obſervations.

After the death of Copernicus, which was on the 23d of May, 1543, Aſtronomy was much improved by Schoner, Nonius, Apian, and Gemma Friſius; though Schoner only ſurvived Copernicus four years. Gemma Friſius was the firſt who propoſed a time-keeper for aſcertaining the longitude at ſea.

About A. D. 1561, William the IVth, Langrave of Heſſe Caſſel, applied himſelf to the ſtudy of this Science, and erected an obſervatory on the top of his palace, and afterwards gave a catalogue of the latitudes and longitudes of 400 ſtars from his own obſervations.

Tycho Brache was cotemporary with the Landgrave of Heſſe beforementioned; he made a vaſt number of obſervations, and publiſhed a catalogue of 770 ſtars.

He invented a new Syſtem of the World, which he vainly endeavoured to eſtabliſh on the ruins of that of Copernicus; but the conſonancy and ſimplicity of the Copernican Syſtem ſoon prevailed over the unnatural and complicated Syſtem of Tycho.

But, notwithſtanding his odd notion of the Univerſe, his works diſcover him to have been a man of vaſt abilities.

The famous John Kepler, was for ſome time under the tuition of Tycho Brache; but he ſoon diſcovered the error of Tycho's Syſtem, and alſo found that his predeceſſors had been wrong in ſuppoſing the orbits of the Planets to be circular; for from his own obſervations he found them to be eliptical, and the Sun to be placed in one of the foci; he alſo diſcovered that all the Planets deſcribe equal areas in equal times,and that the ſquares of the periodical times round the ſun are as the cubes of their mean diſtances.

He likewiſe diſcovered ſomething of the principle of gravity; for he ſignified that gravity is a mutual power betwixt two bodies; that the moon and earth tend towards each other, and would meet in a point nearer to the earth than the moon in the proportion of the ſuperior magnitude of the former; provided they were not hindered by their projectile motions. He further added, that the tides ariſe from the gravitation of the waters towards the moon.

But though Keplar, from the obſervations he made, went thus far, yet the true theory of the planetary motions, as reſulting from the principles of mechanics, and the doctrine of centripetal forces, he was an utter ſtranger to; and therefore it is not to be wondered at that he afterwards did not ſteadily adhere to thoſe principles, but in lieu thereof ſubſtituted others as the cauſes of the planetary motions.

The buſineſs of adjuſting and demonſtrating theſe matters; of determining the true figures of the planets' orbits, and ſhewing that the irregular motions of the Satellites, &c. are perfectly conformable to the laws of motion and gravity, was reſerved for the immortal Engliſh philoſopher Sir Iſaac Newton, to whom aſtronomy, philoſophy, and the various branches of the mathematical ſciences, are indebted for almoſt every thing that is truly valuable.

Galileus, an Italian, in the beginning of the 17th century, by the help of teleſcopes, diſcovered the Satellites of Jupiter, and Saturn, the ring of Saturn, &c.

In 1636, Mr. Jeremiah Horrox foretold a tranſit of Venus that would happen on November 24th, 1639; he alſo formed a new theory of the moon, ſo ingenious as to attract the notice of Sir Iſaac Newton; but the hopes of Aſtronomers, from the abilities of this excellent young man, were blaſted, by his death in January 1640, he being then only about 22 years of age.

Mr. John Flamſtead, the firſt Aſtronomer Royal in this kingdom, made many obſervations on the Sun, Moon, Planets, and Comets; and on the ſtars alſo; publiſhing a catalogue of 3000. He likewiſe publiſhed new ſolar tables, and a theory of the moon, according to Horrox,; and it was from his obſervations that Dr. Halley's tables and Sir Iſaac Newton's theory of the moon were conſtructed.

Mr. Flamſtead died A. D. 1719, and was ſucceeded by Dr. Halley, a moſt excellent Aſtronomer and Mathematician, as appears clearly by his writings in the Philoſophical Tranſactions. He was the firſt who diſcovered the acceleration of the Moon; and gave a very ingenious method of finding her parallax by three obſerved phaſes of a Solar Eclipſe. He compoſed a complete ſet of tables of the ſun, moon, and all the planets, except the Georgium Sidus, ſince diſcovered; and, in the courſe of nine years ſpent at the Obſervatory, he made near 1500 obſervations of the Moon.

Dr. Halley dying, A. D. 1742, was ſucceeded by Dr. Bradley, who was a moſt accurate obſerver, and who diſcovered the aberration of light, and the mutation of the earth's axis. He alſo obſerved the places and computed the elements of the comets which appeared in the years 1723, 1736, 1743, and 1757.

He made new and accurate tables of Jupiter's Sallellites, and accompliſhed various other improvements in aſtronomy too tedious to mention.

Dr. Bradley died A. D. 1762, and was ſucceeded by Mr. Bliſs, Savilian Profeſſor of Aſtronomy at Oxford, who died ſoon after, and was ſucceeded by Nevile Maſkelyne, D. D. the preſent Aſtronomer Royal.

The moſt remarkable foreign Aſtronomers ſince Mr. Flamſtead's time are M. De la Caille, Clairault, Euler, Mayer, Wargentine, and M. De la Lande, all of whom have ſhewn great genius and induſtry in improving aſtronomical tables.

M. De la Lande's planetary tables, Mayer's lunar tables, as improved by Maſon, and Wargentine's tables of the Satellites are ſuppoſed the moſt correct, and are uſed by our preſent Aſtronomer Royal in calculating the Nautical Ephemeris for the uſe of the navy.

But, perhaps, the greateſt aſtronomer of the preſent time is Dr. Herſchel, who, through his wonderful improvement of teleſcopes, has explored the celeſtial regions far beyond whatever had been done; and has diſcovered the new planet Georgium Sidus, and an immenſe number of ſtars that were totally unknown before. By his diſcoveries among the fixed ſtars he has greatly enlarged our ideas of the univerſe. In ſhort, if I may venture to judge of his abilities from the ſpecimens which I have ſeen, I think him a man in every reſpect qualified to perfect all that the Great Newton left unfiniſhed.

SECT. II.

ON THE SOLAR SYSTEM.

MANY hypotheſes have been formed for explaining the motions and appearances of the ſun and planets, &c. but none, except the following, could account for all the phænomena of theſe celeſtial bodies.

This hypotheſis, as has been obſerved, was firſt advanced by Pythagoras; revived ſince by Copernicus and Keplar; and then fully eſtabliſhed and demonſtrated by the immortal Newton.

In this ſyſtem the ſun is placed nearly immoveable in the centre of the orbits of all the planets, or more properly ſpeaking in one of the foci of their reſpective orbits, for the orbits are not circular but eliptical. And though the ſun always keeps nearly in the ſame place, yet he is obſerved to move round his own axis in about 25 days 15 hours and 16 minutes. The orbits of the planets are not all in one plane, but interſect one another in lines that paſs through the centre of the ſun; and the places of the orbits where they interſect are called the Nodes.

The number of planets (including the Earth) are 7; namely Mercury, Venus, the Earth, Mars, Jupiter, Saturn, and the *new diſcovered planet* GEORGIUM SIDUS. Theſe all move round the ſun in the manner above deſcribed, and in the order they are inſerted, Mercury being ſtationed the neareſt to the ſun, and the Georgium Sidus, at the moſt remote diſtance from him. Alſo ſome of theſe planets have attendants called Secondary Planets, or Satellites, moving round them. Thus our ſatellite the MOON revolves round the earth; alſo four moons or ſatellites revolve round Jupiter; five round Saturn; and two round the Georgium Sidus. Theſe likewiſe revolve from Weſt to Eaſt; but none of them, except the Moon, were obſerved before the invention of teleſcopes. The diſtances, magnitudes, revolutions, &c. of the planets and ſatellites will be ſhewn hereafter.

But beſides the planets and their ſatellites, there is another ſort of bodies revolving round the ſun, called wandering Stars or Comets. Theſe move in eliptical orbits, which extend to almoſt an immenſe diſtance from the ſun, or it may be that the orbits of ſome of them are of the parabolic kind, in which caſe, after they diſappear, they are never more ſeen, as they muſt, according to the laws of gravitation, proceed on to eternity through open ſpace without returning to perform a revolution.

The comets move round the ſun in all manner of directions, and cut the plane of the earth's orbit in all ſorts of angles, ſome of them proceeding the ſame way as the planets, and others the contrary way.

Plate III. *Fig*. 1, is a repreſentation of the ſolar ſyſtem. The fixed ſtars do not belong to this ſyſtem; but, it is probable, are as ſo many ſuns to other ſyſtems. The diſtance of the neareſt of them is aſtoniſhingly great; for let the earth be in what part of its orbit ſoever, they ſtill appear to be in the ſame places; and therefore a globe, whoſe diameter is equal to the earth's orbit, if viewed from a fixed ſtar, at the diſtance of the earth, would appear as a point.

The characters of the Sun and Planets are as follow: the Sun, ☉; Mercury, ☿; Venus, ♀; the Earth, ⊕; Mars, ♂; Jupiter, ♃; Saturn, ♄; and the Moon, ☾.

Other Syſtems of the Univerſe, as I have before obſerved, have been propoſed at different times, as

THE PTOLEMAIC SYSTEM, which ſuppoſes the earth at reſt in the centre of the world, and the planets moving round him in circles; as firſt the Moon, then Mercury, next Venus; then the Sun, and above him Mars; then Jupiter; and next Saturn; and laſtly the ſphere of the fixed ſtars; the planets and ſtars being all ſuppoſed to move round the earth in the ſpace of 24 hours.

THE TYCHONIC SYSTEM ſuppoſes the earth abſolutely at reſt; that the moon and ſun revolve about the earth, the moon in a month, and the ſun in a year; and that the reſt of the planets, Mercury, Venus, Mars, Jupiter, and Saturn, revolve round the ſun, the three laſt encompaſſing the earth. Moreover both the planets and ſtars are all ſuppoſed to have a diurnal motion round the earth.

THE SEMI-TYCHONIC SYSTEM ſuppoſes the planets to revolve round the ſun, while the ſun and moon revolve round the earth as their centre of motion, and it ſuppoſes the earth to move about its axis from Weſt to Eaſt in 24 hours. This differs from the *Tychonic Syſtem*, only in this, that it ſuppoſes a diurnal motion of the earth, though, like the *Tychonic*, it denies an annual one.

But none of theſe latter mentioned ſyſtems can account for all the phænomena, and therefore are juſtly exploded; while, on the other hand, the ſyſtem which I have firſt deſcribed, will ſolve every appearance in nature; and its truth is demonſtrable with mathematical certainty.

SECT. III.

AN EXPLANATION OF THE RISING AND SETTING OF THE SUN, MOON, AND STARS; THE CAUSE OF DAY AND NIGHT, &c.

THE phænomena of the apparent motion of the ſun, occaſioned by the real diurnal motion of the earth, is explained thus. See Plate III. *fig*. 2.

Let FGHI be the earth; O, its centre; and let it revolve about an axis perpendicular to the plane of the figure, in the order IFGH, that is, from Weſt to Eaſt.

Let A be the ſun; draw AFOHG and GOI perpendicular to it; alſo ſuppoſe a ſpectator placed at I; then ſince A is at an immenſe diſtance, a ray of light iſſuing therefrom will nearly reach the point I; or, which is the ſame, a line drawn from A as a tangent to the earth's ſurface will nearly touch the earth in the point I, and therefore the ſun at A will be riſing in the horizon at I. As the earth moves round, the ſpectator is carried towards F, and the ſun at A ſeems to riſe gradually higher, till the ſpectator is arrived at F, when the ſun is at the higheſt. When the ſpectator comes towards G, the ſun appears to deſcend, as if it moved towards D; and when the ſpectator is arrived at G, then the ſun appears in the tangent or horizon at G, and therefore the ſun is then ſetting. While the ſpectator is moved through GHI, the ſun is inviſible, being under the horizon, till the ſpectator arrives at I, when it ſeems to riſe again.

Now, it is evident, that while that part of the earth on which the ſpectator is ſituate, is illuminated, that it is day-light; and whilſt he is carried through the dark hemiſphere, GHI, it is night; the points F and H, being noon and midnight. And thus the viciſſitude of day and night appears by the rotation of the earth round its axis.

What has been ſaid of the ſun, is equally true of the moon; or any ſtar placed at A; and therefore all the celeſtial bodies ſeem to riſe and ſet by turns one after another, according to their various ſituations. For let A, B, C, D, be four ſtars; when the ſpectator is at I, the ſtar A riſes, and when at G, it ſets; when at F, the ſtar B riſes, and when at H, it ſets. And when the ſpectator is at G, the ſtar C riſes, and when at I, it ſets; alſo when the ſpectator comes to H, D riſes, and when at F, it ſets. And thus for others, according to their particular poſitions.

The Earth's Diurnal Motion may be proved thus:

It is clear that either the earth muſt move round its axis once in 24 hours, or elſe the heavens, with all their furniture, muſt revolve round the earth in the ſame time.

Now if any body revolve round another as its centre, it is evident, from the laws of motion and the doctrine of centripetal forces, that the central body muſt always be in the plane in which the revolving body moves, let the curve deſcribed be what it may. Wherefore, if the ſun moves round the earth in a day, the earth muſt be in a plane deſcribed by the ſun in a day: but this does not happen, except on two days in the year, viz. at the equinoxes, for at all other times the ſun is vertical to, and apparently moves round, parallel circles, which have not the earth for their centre; conſequently the ſun in ſuch caſe can no more be ſaid to revolve about the earth, than a body moving round the baſe of a cone can be ſaid to revolve about the vertex. On the other hand, allowing the earth's diurnal and annual motion, the ſun is always in the plane of the earth's orbit, which is agreeable to the laws of nature, and is obſerved by the other planets and by all the ſatellites. Wherefore the diurnal motion belongs to the earth, and not to the ſun.

SECT. IV.

See Plate III. *Fig.* 3.

AN EXPLANATION OF THE DIFFERENT SEASONS OF THE YEAR, WITH THE REASON OF THE LENGTHNING AND SHORTNING OF DAYS, &c.

The orbit of the earth extended to the heavens is called the ecliptic, and is divided by Aſtronomers into 12 equal parts, called ſigns, as will be afterwards more fully explained. Now this orbit is ſo ſmall in reſpect to the diſtance of the fixed ſtars, that the ſame aſpect of the heavens will appear whether a ſpectator is placed on the earth or on the ſun. Therefore, if the earth be at ♈, a ſpectator will ſee the ſun in ♎, and when the earth comes to ♉ he will ſee the ſun in ♏, and the ſun will appear to have moved through ♎ ♏. Again, whilſt the earth is moving to ♊, the ſun will ſeem to paſs through ♏ ♐; and, hence, a perſon on the earth obſerves the ſun to go through the ſame ſpace in the heavens, as the earth would appear to go through to a ſpectator at the ſun. And becauſe a ſpectator at the earth is not ſenſible of the earth's motion, he aſcribes that motion to the ſun which in reality belongs to the earth.

Let NEAQ be the earth, and let NA be its axis; N, the north pole; A, the ſouth pole; and EQ, the equinoctial. Alſo let PR be a parallel of latitude, paſſing through any place; and let a plane G♈I be drawn perpendicular to ♑S♋, dividing the illuminated hemiſphere from the dark one. Now the axis NA is inclined to the plane of the ecliptic, or earth's orbit, in an angle of about 66°½; and during the earth's motion in its orbit the axis always remains in a parallel poſition, or pointing to the ſame ſtar. Moreover the earth moves uniformly round its axis, and therefore deſcribes equal diurnal arcs in equal times. Now let the earth be at ♎, then the circle dividing the light and dark hemiſpheres paſſes through the poles N and A; and conſequently by the nature of the ſphere, divides all the parallels, as PR into two equal parts, and therefore any point in that parallel will ſtay as long in the light, as in the dark hemiſphere; that is, the days and nights will be equal. Then, as it moves to ♏, the pole N, comes into the light hemiſphere, by reaſon of the oblique poſition and parallel motion of the axis NA; and as it proceeds to ♐ and ♑, the light hemiſphere reaches gradually farther beyond N; till coming to ♑, it is at the fartheſt, reaching to G, and making the arc NG = 23°½, the complement of N♑S, or 66°½; at which time the oppoſite pole A is as far involved in the dark hemiſphere. Whence, in north latitudes, or in the hemiſphere ENQ, the days have been increaſing from ♎ to ♑, where they are at the longeſt, for the greater part of the parallel PDR, as PD, is in the illuminated, and only the part DR in the dark hemiſphere: but in the oppoſite or ſouthern hemiſphere the days have been decreaſing, and are at their ſhorteſt at ♑; for all the parallels to EQ have their greater part in the dark hemiſphere.

If, through the point G, a parallel be deſcribed, this parallel is called the *Arctic Circle*, and all the ſpace contained therein is illuminated, and therefore there is no night there, whilſt the Earth is at ♑; and, for the ſame reaſon, all the ſpace within the parallel drawn through I, will be dark; and, therefore, all will be night there. Likewiſe, if a parallel be drawn through B, where S ♑ cuts the arc NE, that parallel is called the *Tropic of Cancer*, and the ſun will then ſhine perpendicularly upon the inhabitants of that parallel.

This is the ſummer ſeaſon to thoſe who are in the hemiſphere ENQ, and winter to thoſe who live in EAQ; and ſince EQ is equally divided by the circle of light and darkneſs, GI; therefore the days and nights are always equal under the equinoctial.

Moreover, whilſt the earth moves through ♒, and ♓ to ♈, the circle of light and darkneſs comes gradually nearer to the pole N; and the angle N ♑ G, and conſequently that of B ♑ E, become leſs and leſs, till they vaniſh in ♈; when the circle of light and darkneſs paſſes again through the poles, N and A, and, therefore, biſects all the parallels, as PR; and, conſequently, the days and nights are again equal all over the earth.

Whilſt the earth moves through ♈, ♉, ♊, to ♋, the ſun will ſeem to go through ♎, ♏, ♐, to ♑; when the circle of light and darkneſs will fall ſhort, more and more, of the north pole, N; and will go further and further beyond the ſouth pole A; whence the parallels cut by that circle will have the greater part of the north hemiſphere, PD, in the dark; but, of the ſouthern hemiſphere, the greater part will be illuminated. Therefore 'tis winter to the northern hemiſphere, ENQ, the days being at ſhorteſt, but ſummer to the ſouthern hemiſphere, EAQ, the days there being at the longeſt.

Alſo, within the parallel drawn through G, there will be no day whilſt the earth is at ♋, and, in the parallel drawn through I, there will be no night. At the pole A it will be day for ſix months; and, at the pole N, it will be night for ſix months; being juſt the contrary of what happens when the earth is at ♑. In this poſition, if a parallel be drawn through B, the ſun will ſhine perpendicularly to the earth in that parallel, and it is called the Tropic of Capricorn; alſo a parallel drawn through I is called the Antarctic Circle.

Furthermore, let the earth move from ♋ through ♌ and ♍ to ♎ again, in which caſe it is evident that the circle of light and darkneſs draws gradually nearer to the poles N and A, by which the light and dark parts of the parallels become nearer to an equality, and ſo alſo do the days and nights. Therefore, in the north hemiſphere, ENQ, the days are increaſing; and, in the ſouth hemiſphere, they are decreaſing; and, when the earth arrives at ♎, the days and nights become equal in every place.

Thus it appears, that the different ſeaſons are occaſioned by the obliquity of the earth's axis of rotation to the plane of the earth's orbit; for, if that axis was perpendicular to the plane of the earth's orbit, there could be no variety of ſeaſons, or in the length of days, in whatever part of the orbit the earth was; for there would be a perpetual uniformity, and it would be difficult to determine the length of the year without obſervations of the ſtars.

Scholium. For the ſame reaſons the inhabitants of all the other planets will obſerve the like motions in the ſun, as we do from our earth. For example, an inhabitant of Jupiter would imagine that the ſun turns round him, making a revolution once in twelve years; and, to a ſpectator in Saturn, the ſun would appear to finiſh his period in thirty years.

Since, therefore, it is impoſſible that the ſun can have all theſe motions really in itſelf, and there can be no reaſon aſſigned why any one of them ſhould belong to the ſun more than the reſt, we may ſafely affirm, that there are none of them real, but apparent only, and ariſe from the real motions of the ſeveral planets.

The annual Motion of the Earth may be proved thus:

All obſervations teſtify, that either the earth turns round the ſun, or the ſun round the earth, in ſuch a manner, as that equal areas are deſcribed in equal times; and Sir Iſaac Newton has demonſtrated, that, when two bodies revolve round each other, according to ſuch law, the one muſt of neceſſity gravitate to the other; and, therefore, if the ſun in its motion does gravitate to the earth, action and re-action being equal and contrary, the earth muſt, likewiſe, gravitate to the ſun.

Alſo, Sir Iſaac has demonſtrated, that when two bodies gravitate to one another, without approaching each other in right lines, they muſt both of them turn round their common centre of gravity. The ſun and earth do therefore turn round their common centre of gravity. But the ſun is ſo great a body in reſpect of the earth, that the common centre of gravity of the earth and ſun lies within the body of the ſun, and not far from its centre Wherefore, the earth turns round a point which is within the body of the ſun, and, conſequently, revolves round the ſun; and the ſun turns round a point within himſelf; which obſervations prove to be the caſe.

He has alſo demonſtrated, that if ſeveral bodies gravitate round another, the ſquares of their periodical times will be as the cubes of their mean diſtances from the centre of their orbits: and, by comparing the periods of the planets, with their diſtances from the ſun, as determined from the niceſt obſervations, we find them all in the moſt exact harmony to this law; whereas, on the contrary ſuppoſition, of the ſun and planets revolving round the earth, the whole is deſtitute of any order, being inharmonious, and full of confuſion; for, according to the ſaid law, (which Sir Iſaac has demonſtrated, muſt neceſſarily, without an utter ſubverſion of the laws of nature, obtain in bodies revolving round another) if the ſun moved round the earth, the ſun, in order to harmonize with the motion of the moon, would be above 54700 years in performing one revolution, whereas its *apparent* revolution is but one year. Hence the abſurdity of ſuch a ſyſtem is manifeſt, and the proof of the contrary unanſwerably eſtabliſhed.

SECT. V.

OF THE DIFFERENT PHASES OF THE MOON.

THAT the moon moves round the earth, has been already ſignified in the deſcription of the Solar Syſtem. Her revolution ſhe performs in about twenty-ſeven days and ſeven hours, during which ſhe puts on different phaſes and appearances: for the moon, (like the earth, being a dark, opake, body, and nearly ſpherical, and ſhining by the borrowed light of the ſun) we ſometimes ſee to increaſe and become bigger, and at length appearing with a full globular face, and afterwards, by a gradual diminution, become leſs, till ſhe loſes all her luſtre and diſappears.

Alſo, ſometimes ſhe enlightens us the whole night, and at other times ſhe does not appear till late at night: ſometimes ſhe keeps in the ſouthern hemiſphere, and at other times ſhe riſes high, and viſits the northern hemiſphere.

To illuſtrate her different phaſes as ſeen from the earth, ſee Plate III. *fig.* 4 and 5, where S repreſents the ſun, T the earth, RTS, a portion of the earth's orbit, which it deſcribes in the annual courſe round the ſun. Let ABCDEFG be the orbit of the moon, in which ſhe turns round the earth in the ſpace of a month, from the weſt towards the eaſt.

This motion of the moon is evident to our ſenſes; for, if the moon be obſerved to arrive at the meridian any night with a fixed ſtar, the next night ſhe will be 52 minutes later in coming to the meridian, or in ſouthing, than the ſtar, ſhe having receded from the ſtar about 13 degrees towards the eaſt. Join the centres of the ſun and moon with the right line SL, and, through the centre of the moon, imagine a plane MNL to paſs, to which the line SL is perpendicular: the ſection of that plane with the ſurface of the moon, will produce the circle which bounds light and darkneſs in her, and ſeparates the enlightened face from the dark and obſcure ſide. In the ſame manner let the centres of the earth and moon be joined by the right line TL, which is perpendicular to a plane PLO, paſſing through the centre of the moon; that plane will make on the ſurface of the moon, the circle which diſtinguiſheth the viſible hemiſphere, or that which is towards us, from the inviſible, which is turned from us; which circle may therefore be termed the Circle of Viſion.

Hence it is manifeſt, that whenever the moon is in the poſition A, in the point of its orbit oppoſite to the ſun, that then the circle bounding light and darkneſs, and the circle of viſion, do coincide, and that all the illuminated face of the moon will be turned towards the earth, and be viſible by its inhabitants; and then the moon is ſaid to be full, and ſhe ſhines all night long; and in reſpect to the ſun, ſhe is ſaid to be in oppoſition: for the ſun and moon are ſeen in oppoſite parts of the heavens, the one riſing where the other ſets. When the moon comes to B, the whole illuminated diſk, MPN, is not turned towards the earth, there being a part of it, MP, not to be ſeen by us; and then the viſible illumination will be deficient from a circle, and the moon will have a gibbous or humped form, ſuch as is marked in B. The moon arriving at C, where the angle CTS is nearly right, there only one half of the illuminated diſk is turned towards the earth, and to be ſeen from thence; and then we obſerve a half moon, as in C, and ſhe is ſaid then to be biſected or dichotomized, that is, cut in halves. In this ſituation, the ſun and moon are a fourth part of a circle removed from each other, and the moon is ſaid to be in a quadrate aſpect, or to be in her quadrature. The moon going forward to D, the illuminated face, MPN, has but a ſmall portion of itſelf turned towards the earth, and the ſide of the moon turned towards the earth is, for the greateſt part, in darkneſs; and therefore, of the ſpherical figure of the moon, which appears to us to be plain, that ſmall part which ſhines upon us, will ſeem to be bended into narrow points or angles, and will look like what we call horns; for there the circle, bounding light and darkneſs with the circle of viſion, doth form two ſmall angles at their interſections, and the phaſis ſeen from the earth will appear as in D. The moon at laſt coming to E, will ſhew no part of its illuminated face to the earth. but all the dark ſide of the moon will be turned towards it; and then the moon diſappears, and ſhe is ſaid to be in conjunction with the ſun, the ſun and ſhe being in the ſame point of the ecliptic. This poſition we call New Moon. When the moon advances further to F, ſhe again aſſumes an horned or crooked figure; and, as before the New Moon the horns were turned weſtward, ſo now, after the time of New Moon, they change their poſitions and look eaſtward. When the moon has proceeded to G, and is again in a quadrate aſpect with the ſun, ſhe will appear biſected, and like a half-moon. In H ſhe will be bigger, but will ſtill be deficient from a whole circle, and be ſeen gibbous: but in A ſhe will again appear circular, and in her full ſplendour.

The arch EL, or the angle STL, contained under lines drawn from the centres of the ſun and moon to the centre of the earth, is called the Elongation of the moon from the ſun. And the arc MO, which is that portion of the illuminated circle MON which is turned towards the earth, and which is the meaſure of the angle that the circle bounding light and darkneſs, and the circle of viſion make with one another, is every where nearly ſimilar to the arc of Elongation EL, or which is the ſame thing, the angle STL is nearly equal to the angle MLO, which I thus demonſtrate. Produce SL at pleaſure unto X, and the angles TLP and MLS will be equal, they being both right angles: but the angles OLS and PLX are alſo equal, becauſe they are vertical to each other; therefore taking away thoſe equal angles, the angle MLO will remain equal to the angle TLX; but the angle TLX is the external angle of the triangle STL, and is therefore equal to both the inward and oppoſite angles STL and TSL, by the 32d Propoſition of Book I. of Euclid. But the angle TSL is exceeding ſmall, and next to nothing; for when biggeſt in the quadratures, it does ſcarce exceed ten minutes of a degree; the diſtance of the moon from the earth in compariſon of that of the ſun being ſo ſmall, that the angle which it ſubtends at the ſun vaniſhes. And therefore the angle STL by itſelf, is nearly equal to the angle MLO; whence the arc MO will be ſimilar, or like to the arc EL.

The ſemicircle OMP, ſince its plane paſſes through the eye, will be projected into a right line, or appear like a right line on the diſk of the moon; but the circle bounding light and darkneſs in the moon, ſince it is ſeen obliquely from the earth, will be projected into an ellipſe, in which form it will appear.

As the moon by reflected light from the ſun illuminates the earth, ſo the earth does more than repay her kindneſs, in enlightening the ſurface of the moon.

In new moons, the illuſtrated ſide of the earth, is fully turned towards the moon, and will therefore at that time illuminate the dark ſide of the moon; and then the Lunarians will have a full earth, as we in a ſimilar poſition have a full moon. And from thence ariſes the dim light which is obſerved in the old and new moons, whereby, beſides the bright and ſhining horns, we can perceive the reſt of her body behind them, though but dark and obſcure. Now when the moon comes to be in oppoſition to the ſun, the earth ſeen from the moon will appear in conjunction with him, and its dark ſide will be turned towards the moon, in which poſition the earth will diſappear; after the ſame manner as the moon does diſappear to us in the time of new moon, or in her conjunction with the ſun: in ſhort the earth will ſhew all the ſame appearances to a ſpectator in the moon, as the moon does to us.

SECT. VI.

OF THE STATIONS AND RETROGRADATIONS OF THE PLANETS.

IF an obſerver was ſituate in the ſun, all the planets would appear to move in due order about him from weſt to eaſt: but to a ſpectator on the earth their motions appear very irregular; ſometimes they appear to move *directly* from weſt to eaſt, according to their true motions, at other times to loſe all their motion and become ſtationary; and by turns they ſeem to move backward, or become retrograde. The cauſe of theſe phænomena will be manifeſt from what follows.

1ſt. With reſpect to the inferior planets ☿ and ♀.

Let ABC, (Plate III. *fig.* 6) repreſent an arc of the celeſtial ſphere; EOP, the earth's orbit; LNIG, the orbit of an inferior planet, as of ♀; and S, the ſun: let the earth at firſt be ſuppoſed to ſtand ſtill in its orbit at E: now, it is evident, that the ſun will appear at the point B, and the planet always within the arc AC. Whilſt the planet moves in its orbit from 1 through Q to N, it will ſeem to move from B to A agreeably to the order of the ſigns, viz. from weſt to eaſt, or as Aſtronomers term it in *conſequentia*: but paſſing from N to L, it will ſeem to an eye at E, to return back from A to B, or be retrograde.

While the planet is at or near the point N, being betwixt moving from B to A, and returning from A to B, and moving as it were in a right line towards the earth, it will for ſometime ſeem to ſtand ſtill near A, that is to be ſtationary. When the planet is in that part of her orbit, N or G, which is contiguous to the tangent EA or EC, ſhe will then appear at A or C, her greateſt diſtance from the ſun, and is ſaid to be in her greateſt ELONGATION. This elongation is meaſured by the angle SEG. The more diſtant a planet is from the ſun, the greater will its angle of elongation be; that of ♀ is about 48°, and of ☿ about 28°.

In the ſpace of a revolution, an inferior planet will, with reſpect to the earth, undergo two conjunctions, one which is beyond the ſun at 1; the other when it is at L, between the ſun and the earth; the former is called the ſuperior, and the latter the inferior conjunction.

Whilſt ♀ goes from her ſuperior conjunction, ſhe appears in the arc AB, always to the eaſtward of the ſun, and therefore ſets ſometime after the ſun, and is called the Evening Star: but during the time ſhe is going from her inferior to her ſuperior conjunction, ſhe will be ſeen ſomewhere in the arc BC to the weſtward of the ſun, and ſo will ſet before him in the evening, and riſe before him in the morning: hence, ſhe is called the Morning Star.

Hitherto the planet has been ſuppoſed to move while the earth ſtood ſtill: but when both move the phœnomina will be much the ſame, only the planet will be more direct in the fartheſt part of the orbit and leſs retrograde; the former ariſing from the ſum of their motions, and the latter from the difference.

2dly. With reſpect to the phœnomina of the ſuperior planets, viz. ♂, ♃, ♄, &c. the *direct*, *ſtationary*, and *retrograde* motions are explained much in the ſame manner as thoſe of the inferior planets, but with theſe differences.

1ſt. The retrograde motions of the ſuperior planets happen oftener, the ſlower their motions are; as the retrogradations of the inferior planets happen oftener, the ſwifter their angular motions are; becauſe the retrograde motions of the ſuperior planets depend upon the motions of the earth, but thoſe of the inferior on their own angular motions.

A ſuperior planet is retrograde once in each revolution of the earth; an inferior one, in every revolution of its own.

2d. The ſuperior planets do not always accompany the ſun, as the inferior do, but are often in oppoſition, which neceſſarily follows from the earth's orbit, being included within the orbits of the ſuperior planets.

SECT. VII.

METHODS OF DETERMINING BY OBSERVATION THE PERIODICAL TIMES OF THE EARTH AND PLANETS, TOGETHER WITH THE MAGNITUDES AND SITUATIONS OF THEIR RESPECTIVE ORBITS, THE PLACES OF THE STARS, &c.

Definitions.

I. THE **Orbit** of a Planet N is the curve line, which it deſcribes about the Sun, as ABPDA, Plate III. *fig.* 7. The orbits of the earth and all the planets are ellipſis, having the ſun in one of the foci, as at S.

II. **The Apsides**, are the two extreme points of the orbit, as A and P. The point A, which is the fartheſt from the ſun, is called the **Aphelion**, or *higher apſis*; and the point P, which is the neareſt to the ſun, is named the **Perihelion**, or *lower apſis*. Alſo the tranſverſe axis AP, is called the **Line of Apsides**.

III. **The Eccentricity** is the diſtance of SC, from the focus to the centre.

IV. **The Mean Distance** of a planet is the line SB drawn from the focus S, to the end B or D of the conjugate axis BD. This line SB is equal to half the tranſverſe axis AC or CP.

The Periodical Time, is the time of a planet's deſcribing its orbit, or of returning to the ſame point in its orbit.

V. **The Nodes** of any orbit are the points where its plane cuts the plane of the earth's orbit, ſuppoſing them both produced to the fixed ſtars, for the planets move in orbits whoſe planes are all different from that of the earth, and from one another. And the ſun being in all theſe planes, they conſequently cut one another in lines paſſing through the ſun.

If ECFD, Plate III. *fig.* 8. be the earth's orbit, and GCHD, the orbit of a planet cutting the earth's orbit in the line CD, then C and D are nodes; and CD the line of the nodes.

That node through which a planet paſſes towards the north pole, is called the **Ascending Node**; and that through which it moves towards the ſouth pole, is named the **Descending Node**.

VII. **The Inclination of a Planet's Orbit** is the angle which the plane of it makes with the earth's orbit or ecliptic, as EDG. This is meaſured by the arc of a circle EG, at a quadrant's diſtance from the nodes.

VIII. **Elongation of a Planet**, is the angle between the ſun and the planet, as taken at the earth; or angle between the ſun and place of a planet reduced to the ecliptic, of which I have ſpoken in Sect. VI.

IX. **Parallax**, is the difference between the real and apparent place of a planet, or the difference of its apparent places, as viewed from the earth's centre, and from ſome given point on its ſurface.

X. **The Annual Parallax**, or Parallax of the earth's orbit, is the difference between the places of a ſtar, as ſeen from oppoſite points of the earth's orbit.

XI. **The Moon's Apogee** is that point in her orbit, which is fartheſt from the earth. This correſponds with the aphelion of a planet.

XII. **The Moon's Perigee** is that point in her orbit, which is the neareſt to the earth. This is the ſame as the perihelion of a planet.

XIII. **The Moon's Synodic Revolution**, is the time that elapſes between her being in conjunction with the ſun, and her coming into conjunction with him again.

XIV. **The Syziges** of the moon's orbit, are the points where a line drawn through the earth and ſun cuts it. Theſe are the points of conjunction and oppoſition.

XV. **The Quadratures** are the points of the moon's orbit, which are at a quadrant's diſtance from the ſyziges; and the **Octants**, are alike diſtant from the ſyziges and quadratures.

Theſe things premiſed, I proceed to the following Problems.

Problem I. *To find the Latitude of a Place.* (See Sect. IX. Definition 43.)

With a good quadrant, or other proper inſtrument, take the altitude of the pole ſtar when it is at the higheſt, which is known by continuing your obſervations till it begins to deſcend. Alſo about 12 hours after, take its altitude when it is at the loweſt; then half the ſum of the two altitudes is the height of the pole, or latitude required.

N. B. Inſtead of the pole ſtar, any other ſtar may be choſen that is out of the power of refraction.

Or thus. If the ſun's declination be known at that time, take his meridian altitude, which you may know by continuing the obſervation till he begins to deſcend. Then if the declination be towards the elevated pole, add it to the complement of the altitude; but, if the declination be contrary, take the difference between the declination and the complement of the altitude, and the reſult in either caſe will be the latitude required.

Problem II. *To draw a Meridian Line in any Place.*

See Plate III. *Fig.* 9.

Upon a plain board placed parallel to the horizon deſcribe a circle ABF; and on the centre C, erect a ſtile or gnomon perpendicular to it, and ſo high that the top of its ſhadow may fall upon the circumference of the circle, about the middle of the forenoon. Mark exactly the point B, where the top of the ſhadow falls in the forenoon. Likewiſe mark the point F, where the top of the ſhadow falls again, on the circumference in the middle of the afternoon. Then through the centre C, draw the line ACD biſecting the arc BF, ſo will AD be the meridian required.

Scholium. It will be proper to draw ſeveral concentric circles, and to make obſervation with them all, that they may confirm each other. It will alſo be beſt to make the obſervations at or near the time of the ſolſtices, when the ſun does not ſenſibly alter his declination; and the ſummer ſolſtice is to be preferred.

Problem III. *To find the Obliquity of the Ecliptic.* (See Sect. IX. Definition 21.)

Take the ſun's meridian altitude at both ſolſtices; ſubtract the leſs from the greater, and take half the difference, and it will be the obliquity required. This is on the ſuppoſition, that the ſun is on the ſame ſide of the zenith at both obſervations; but, if the reverſe is the caſe, add the complements of the two altitudes together, and half the ſum will be the obliquity of the ecliptic. If the obſervations are made when the ſun is low, regard muſt be had to refraction, and the altitude muſt be diminiſhed by a quantity equal to the refraction.

Or thus. If you have the latitude of the place, take the meridian altitude of the ſun at the ſummer ſolſtice, ſubtract its complement from the latitude, and the remainder will be the obliquity ſought.

Scholium. By comparing the obſervations of the ancients with thoſe of modern aſtronomers, it appears that the obliquity of the ecliptic has been continually decreaſing; and is now found to be ſcarce 23° : 28′.

Prob. IV. *To find the Time when the Sun is in the Equinoctial.*

Having the latitude of the place, and conſequently the height of the equator, (or co-latitude) by careful obſervation, take the ſun's meridian altitude on thoſe days when it is equal to the height of the equator, or nearly ſo.

If it ſhould happen to be exactly equal to the co-latitude, the ſuns is at that inſtant in the equinoctial, or on the equator. But if it is greater or leſs than the co-latitude, you muſt obſerve till you get the meridian altitudes on two ſucceſſive days, one greater than it and the other leſs; then the time of his being in the equinox is evidently between the times of theſe obſervations. And to determine the time exactly, the 24 hours elapſed between one obſervation and the other muſt be divided in proportion to the exceſs, and defect of the altitudes; taking the required time nearer to the noon of that day on which there was the leaſt difference between the altitude and co-latitude.

Problem V. *To find the Length of the Year.*

Find by the laſt Problem the time of the ſun's being in the equinoctial, either at the vernal or autumnal equinox. Alſo find the time of his being in the ſame equinox, the year following. Then the intermediate time is the length of the year. This is called the *tropical year*, and is ſomething leſs than the Sydereal year, or the earth's periodical time, on account of the preceſſion of the equinoxes; or it will be more exact, if the time of the ſun's entering into the ſame equinox be taken at ſeveral years diſtance; for if the whole time between the obſervations be divided by the number of years, it will give the length of the tropical year exactly. By this means the length of the tropical year is found to be 365 days, 5 hours, 48 minutes, 57 ſeconds.

In like manner the length of the Sydereal year is found by taking the time between the ſun's leaving any fixed ſtar, and returning to it again, after a great many years, and dividing it by the number of years; or it may be found by comparing the place of a fixed ſtar according as it was obſerved many years ſince with its preſent place; for the difference divided by the number of years, will give the annual preceſſion of the equinoxes, which reduced into time, and added to the *tropical year*, you will have the length of the Sydereal year. This preceſſion of the equinoxes is about

$50'$ yearly, and therefore the Sydereal year is 365 days, 6 hours, 9 minutes, 14 ſeconds.

N. B. By obſervations it is found that the time from the vernal to the autumnal equinox is 186 days, 12 hours, 29 minutes, 30 ſeconds; and from the autumnal to the vernal equinox only 178 days, 17 hours, 19 minutes, 30 ſeconds, ſo that the ſummer half year exceeds the winter by 7 days, 19 hours, and 10 minutes.

PROBLEM VI. *To find the Eccentricity of the Earth's Orbit and its Form.*

Make ſeveral obſervations of the ſun about the time when he is in the aphelion, and continue to take his apparent diameter, till you find it at the leaſt.

At half a year's diſtance, when he is about the perihelion, obſerve his apparent diameter till you find it at its greateſt; then through any point as S (Plate III. *fig.* 10.) draw a line PSA, and from S take SP to SA as the ſun's leaſt apparent to his greateſt apparent diameter, ſo will A and P be the aphelion and perihelion of its orbit. Alſo make SC and CF equal to half the difference between SA and SP; and F will be the other focus and C the centre. Then the ellipſis ABPD whoſe foci are S and F will be the form of the orbit; for the diſtance is reciprocally as the apparent diameter.

Or thus. Obſerve with a teleſcope and micrometer what the apparent motion of the ſun is when ſloweſt, and (half a year after) how much his apparent motion is when ſwifteſt. Take SA to SP as the ſquare root of the ſwifteſt motion to the ſquare root of the ſloweſt, ſo will A and P be the aphelion and perihelion; and the reſt will be found as before. By theſe methods the earth's excentricity is found to be 168; ſuppoſing the mean diſtance, or half the tranſverſe axis to be 10000.

PROBLEM VII. *To find the Place of the Earth's Aphelion, or the Poſition of the Apſides, together with the Time when it is in the Aphelion.*

Obſerve two places of the ſun at a good diſtance from each other, and where the apparent motion is the ſame, or where the apparent magnitude is the ſame. Let theſe places be C and B (Plate III. *fig.* 11). Biſect the arc BC by the line AF; ſo will A be the aphelion if the magnitude or motion was decreaſing towards A; otherwiſe it is the perihelion. Whence the place of the aphelion is had; and the poſition of the apſides AP. Alſo, if the times be noted when the earth is in C and B, then the mean time between them will be the time when the earth is in the aphelion A.

SCHOLIUM. If the difference between the place of the earth's aphelion ſeveral years paſt, and its preſent place, be divided by the number of years, the quotient will ſhew the annual motion of the aphelion, which is $1' 0'' 37'''$ in a year.

Note alſo, the time of the earth's revolving from aphelion to aphelion is called the ANOMALISTIC YEAR; and, according to Dr. Halley, is 365 days, 6 hours, 13 minutes, 32 ſeconds.

PROBLEM VIII. *To find the Declination of a Star.*

The obſerver being furniſhed with a large quadrant fixed in the plane of the meridian, with an index moving round its centre, and teleſcopic ſights, he muſt wait the ſtar's coming upon the meridian, and take its meridian altitude. If the ſtar be towards the equinoctial, and on the North ſide of it, take the difference between the altitude, and colatitude of the place, and the remainder will be the declination North: But if the ſtar be on the South ſide of the equinoctial, then the remainder is the declination South.

Again, if the ſtar be towards the Pole, take the difference between its altitude and the latitude of the place, and it will be the complement of the ſtars declination, which will be North, or South, according as the ſtar and place ſhall be towards the North or South Pole.

PROBLEM IX. *To find the right Aſcenſion of a Star.*

Having a good time piece with minutes and ſeconds, let it be ſo adjuſted that the hand may go through the 24 hours in a Sydereal day, viz. in 23 hours, 56 minutes, 4 ſeconds; then obſerve when the ſun, of known ſtar, is in the meridian, and ſet the clock at that inſtant to the time of the ſun or ſtar's right aſcenſion, and obſerve alſo when the unknown ſtar comes to the meridian; and mark the time exactly, as ſhewn by the time piece, and it will be that ſtar's right aſcenſion in time, which may be reduced into degrees and minutes, by proportioning 15° to 1 hour.

PROBLEM X. *To find the periodic Time of a Planet.*

The planet muſt be obſerved ſeveral times, till it be found to have no latitude, and is therefore in its node. Alſo it muſt be obſerved in like manner when it returns again into the ſame part of its orbit; then the time elapſed between its being in its node, and returning to the ſame again, is the periodic time of the planet. But it will be more exact if the planet be obſerved in its node, at the diſtance of ſeveral revolutions; for the elapſed time, divided by the number of revolutions, will give the periodic time required; and the more the revolutions, the more exact will be the reſult.

PROBLEM XI. *To find the Nodes of a Planet's Orbit, and the Planet's Diſtance from the Sun at that Time.*

Let ABD (Plate III. *fig.* 12) be the earth's orbit; FNQ, that of a ſuperior planet; S the ſun; NSQ, the line of nodes.

Take two obſervations when the planet is in the node N; and let the places of the earth, at theſe times, (ſuppoſed to be given) be A and B. Then, in the triangle ASB, there is given the ſides BS and AS, and the included ∠ ASB, to find the ſide AB, and angles at A and B.

Alſo, the angles, SAN and NBS, being known by obſervation, we have the angles NAB and NBA.

Likewiſe, in the triangle ABN, there are given the angles and the ſide AB to find NA, the planet's place from the earth.

Laſtly, in the triangle NAS, we have the ſides NA and AS, with the angle NAS, to find NS, the diſtance of the planet from the ſun, when it is in the node at N, and the angle ASN, which determines the place of the node, and the poſition of the line of nodes, NSQ.

The calculation will be the ſame for an inferior planet, *mutatis mutandis.*

PROBLEM XII. *To find the Inclination of a Planet's Orbit.*

Let the orbit of the planet be PDG, (Plate III. *fig.* 13) that of the earth, BEQ, and N*n*, the line of the nodes.

At the time when the earth is at Q, in the line of the nodes, obſerve accurately the longitude of the planet at P from the ſun, or the angle OQS, and alſo its latitude PQO. Then it will be, as the ſine of the angle, SQO : radius : : tangent of latitude, PQO : tangent of the inclination of the orbit. For PO being perpendicular to the plane of the ecliptic, and PQ and OQ being drawn, as alſo OB, perpendicular to N*n*, the angle BPO will be the inclination of the orbit. Now, in the right-angled triangles, QPO and BPO, we have, OB : ſine OQB : : QO : radius : : PO : tangent PQO. And, alternately, As ſine OQB : tangent PQO : : OB : PO : : radius : tangent PBO.

PROBLEM XIII. *To find a Planet's Orbit, Place of Aphelion, and the Time of its being in its Perihelion.*

Let *n*PN, in the foregoing figure, be the planet's orbit; AEQ, the earth's; S, the ſun; and N*n*, the line of nodes.

Alſo, (the earth's motion in its orbit, and the inclination of the planet's orbit, being ſuppoſed to be known) let the planet be at P in oppoſition to the ſun, the earth being at E. Then draw PO perpendicular to the ecliptic; likewiſe draw SEO; O being the planet's place reduced to the ecliptic. Obſerve the quantity of the angle PEO, the planet's latitude ſeen from the earth.

Then, ſince the ſun's place is known, the planet's place, being oppoſite to it, is known; and, conſequently, its diſtance from the node O*n*, is alſo known. Therefore, in the ſpherical triangle, *n*PO, the ſide O*n*, and the angle O*n*P are known; and hence the ſide P*n* will be known, as alſo PO, which is the meaſure of the angle PSO, the latitude of the planet ſeen from the ſun.

Likewiſe, SE is known, being the earth's diſtance from the ſun. Therefore, in the triangle PSE, having all the angles and the ſide SE, the planet's diſtance, SP, from the ſun, becomes known. Conſequently, we have the planet's place in its own orbit.

And, by taking in this manner two more obſervations of the ſame planet, in a poſition oppoſite the ſun, we ſhall have two more places, D and G, of the planet's orbit.

Hence we have the magnitude and poſition of three lines, SP, SD, and SG, drawn from the focus of an ellipſis; and, conſequently, the curve may be deſcribed, which will be the orbit of the planet, and from thence every requiſite may be determined.

The application of this method is confined to the ſuperior planets.

The following Method is applicable to an inferior Planet.

Let GHI be the earth's orbit, (Plate III. *fig.* 14) APE, the planet's orbit; S, the ſun; and DSN, the line of the nodes. Let the planet be at P, whilſt the earth is in any place T. Draw PB perpendicular to the plane of the ecliptic, and TB to meet the line of the nodes in N. Alſo, draw SB and TC parallel to BP, and make TD perpendicular to DN, and join CD, then the ∠ TDC is the inclination of the orbit. Therefore, the ∠ BTP, the planet's latitude at the earth, and the ∠ BTS, its diſtance from the ſun in the ecliptic, being obſerved, there are given in the triangle NTS, ST, the ſide or diſtance of the earth and ſun; the ∠ TSN, or the earth's diſtance from the node; and the ∠ NTS, or BTS, to find NT; and, in the right-angled triangle, TSD, we have TS, and ∠ TSD, to find TD. Alſo, in the right-angled triangle, TDE, we have TD and ∠ TDC, to find TC; and, in the right-angled triangle, TCN, there are TC and NT to find ∠ TNC.

Likewiſe, in the triangle NTP, we have the ∠ NTP or BTP, and PNT or CNT, together with the ſide NT, to find TP; and, in the right-angled triangle, PTB, we have TP, and ∠ PTB, to find BT and BP.

Furthermore, in the triangle TSB there will be given TB and TS, and ∠ BTS, to find SB and ∠ TSB, which is the place of the planet reduced to the ecliptic: then, in the right-angled triangle PBS, there are had the ſides PB and BS, to find SP, the planet's diſtance from the ſun, and ∠ PSB, the planet's latitude ſeen from the ſun.

Again, in the right-angled ſpherical triangle, APB, we have PB and ∠ PAB, to find AB and AP. Conſequently, the planet's place in his orbit is known, and alſo his diſtance from the ſun.

And, if by this method two more places of the planet are found, and its diſtances from the ſun, there will be three lines drawn from the focus of an ellipſis given in magnitude and poſition, to deſcribe the ellipſis, (for the performance of which ſee CONIC SECTIONS) which ellipſis will be a juſt deſcription of the planet's orbit.

PROBLEM XIV. *To find the greateſt Elongation of an inferior Planet.*

Let ABD (Plate III. *fig.* 14) be the orbit of the planet; E, a point in the earth's orbit, and S, the ſun. Then, from the point E, draw the line EB to touch the orbit, ABD, of the inferior planet, and the angle SEB will be the planet's greateſt elongation. Draw, therefore, SB to the point of contact B, and it will be perpendicular to the tangent EB: whence, in the right-angled triangle ESB, there are given ES and SB, the diſtances of the earth and planet from the ſun, to find the angle SEB, the elongation.

But, to do this experimentally, the greateſt elongation, SEB, muſt be repeatedly taken by an inſtrument when it is about the extremity of its orbit, and the greateſt angle contained between the ſun and planet, is that ſought.

But, in elliptical orbits, the ſame ſhould be repeated ſeveral times, when the earth and planets are in different parts of their orbits, and the greateſt obſerved angle is the elongation required.

PROBLEM XV. *To find the Parallax of a Planet.*

Let AD (Plate III. *fig.* 15) be the earth; C, its centre; P, the planet; and let the planet's diſtance, CP, from the centre of the earth, be given. Then the angle ZAP is the complement of the apparent altitude, and ZCP, the complement of the true altitude. And it will be, as CP : earth's radius AC : : ſine $\angle$ ZAP : ſine $\angle$ CPA = the parallax.

Or thus: If the diſtances of two planets or ſtars, having the ſame apparent altitude, and alſo the parallax of one of them be known, and if P and G be the planets in the line APG, then $\angle$ APC is the parallax of P, and $\angle$ AGC the parallax of G. Hence, in the triangle, CPG, there are had CP, CG, and an angle oppoſite, (as G) to find the other oppoſite angle. Conſequently, as diſtance CP : diſtance CG : : ſine $\angle$ CGP : ſine $\angle$ CPG or CPA: that is, the ſines of the parallaxes are reciprocally as the diſtances from the earth's centre.

COR. I. The parallaxes of two planets are as the coſines of the apparent altitudes directly, and their diſtances from the earth's centre reciprocally.

COR. II. The horizontal parallax of one body ſeen from another, is equal to the apparent ſemi-diameter of that other ſeen from the firſt.

PROBLEM XVI. *Having the Parallax of a Planet, and its Poſition in reſpect of the Ecliptic and Circles of Longitude, &c. to find the Parallax of Latitude and Longitude; or the Parallax of Right Aſcenſion and Declination.*

Let HO (Plate III. *fig.* 16) be the horizon; EC, the ecliptic; Z, the zenith; P, the pole of EC; S, the apparent place of a planet; ZSB, a vertical circle drawn through the planet; A, the true place of the planet; PAL and PSI, circles of longitude. Draw AD parallel to EC: then AS is the parallax of altitude, SD, the parallax of latitude, and LI, the parallax of longitude; L being the true place of the planet reduced to the ecliptic, and I the apparent place. Therefore, having AS and $\angle$ ASD in the ſmall right-angled triangle ASD, the parallax of latitude, SD, will be had, and the ſide AD.

Wherefore, in the triangles PAD and PLI, it will be, as ſine PD : radius : : AD : LI, the parallax of longitude.

Alſo, whether it is to be added to, or ſubtracted from the longitude at L, will eaſily appear, by the poſition of the circles EC, ZB, and PL.

But if EC be the equinoctial, and P its pole, then SD will be the parallax of declination, and LI the parallax of right aſcenſion.

COR. I. If the circles PS and ZS coincide, SD will be equal to AS, and $AD = 0$. That is, the parallax of longitude or right aſcenſion is nothing, and the parallax of latitude or declination is equal to the parallax of altitude.

COR. II. If the circles EC and ZS coincide, then $AS = LI$, and $SD = 0$. That is, the parallax of longitude or right aſcenſion (as the caſe is) is equal to the parallax of altitude: and the parallax of latitude or declination is nothing.

PROBLEM XVII. *To find the Moon's Periodical Time, Orbit, and Parallax.*

I. The moon's periodic time is known by obſerving the diſtance of time between her conjunction with any fixed ſtar, and her next returning to the ſame ſtar again. But this being different at different times, it will be proper to take the time between her conjunction with any known ſtar, as obſerved ſeveral years ſince, and her preſent conjunction with the ſame ſtar, and divide it by the number of her revolutions, within that period, and it will give her mean periodic time, which is 27 days, 7 hours, 43 minutes, 12 ſeconds, being ſomething more than the time of her return to the ſame point of the ecliptic, which is 27 d. 7 h. 43 m. 5″.

II. The time of the moon's ſynodic revolution, or the time of her revolving from conjunction to conjunction with the ſun, is found in the ſame manner by two obſervations, made at a conſiderable diſtance of time from each other, and has been determined at 29 d. 12 h. 44 m. 3″.

III. To find the parallax, proceed as in Problem XV. or as follows:

In an eclipſe of the moon, obſerve when the horns of the moon are in the ſame vertical circle, and at that moment take the altitude of both the horns: then half the ſum is the apparent altitude of the moon's centre.

Now the place of the ſun in the ecliptic is known, and conſequently the place of the centre of the earth's ſhadow, which is oppoſite to it is alſo known; and the altitude of the moon, at that time, is equal to the altitude of the centre of the ſhadow, becauſe they are both in a line parallel to the horizon. Hence find the altitude of that point of the ecliptic in which the centre of the ſhadow is, from which ſubtract the apparent altitude of the moon, and the remainder is her parallax: and thus her mean horizontal parallax is found to be about 57′ 12″.

IV. To find her diſtance. Let AD (Plate III. *fig.* 17) be the earth, whoſe centre is C, and A the place of obſervation; and let F be the place of the moon. Find her parallax, as above directed, and her apparent diameter; then in the triangle AFC, we have the angle F, or parallax, and the angle CAF, (the ſupplement of ZAF) her apparent zenith diſtance, to find her apparent diſtance AF.

Now if G be another place of the moon whoſe diſtance is ſought, then the moon's apparent diameter at G muſt be obſerved, and her altitude BAG; and it will be, as her apparent diameter at G : her apparent diameter at F : : AF : AG.

Now in the triangle CAG, having the ſides AG, AC, and CAG, (= right-angle CAB + altitude BAG) the ſide CG will be found, or her mean diſtance from the earth's centre = 60.3 of the earth's radius at her mean diſtance.

V. *To find the tranſverſe Axis of her Orbit and Eccentricity.*

Find her diſtance from the earth's centre by a great number of obſervations, continued through her period (as in Art. IV.) Out of theſe ſelect the greateſt and leaſt, and the ſum of them is the greater axis of her orbit; and half the difference is the eccentricity. After this manner it is found, that the moon's mean eccentricity is about 55 of ſuch parts as her mean diſtance contains 1000.

VI. *To find the Place of the Moon's Apogee.*

Obſerve two places of the moon when ſhe has the ſame apparent diameter, and the ſame altitude; biſect that arc to find the intermediate place, for the apſis of her orbit paſſes through it, and conſequently the poſition of the apſis is known. Alſo, that point where the apparent diameter is the leaſt, is the apogee; and, by comparing two ſucceſſive revolutions, the motion of the apogee will be known. Or it may be more exactly determined by dividing the whole ſpace gone through in a long time by the number of revolutions.

By this method it has been found, that the apogee makes a revolution, *in conſequentia*, to the ſame point of the cliptic in 8 years, 309 days, 8 hours, 20 minutes.

VII. To find the place of her nodes; obſerve the latitude of the moon ſeveral times, till you find it to be nothing, allowing for the parallax, and that is the place of her node. If the moon be advancing northward, it is the aſcending node; but if ſouthward, it is the deſcending node.

The motion of the moon's nodes may be found by comparing their places at a diſtant period with the preſent time. By obſervation it is found, that the motion of the nodes is retrograde, and makes a revolution to the ſame point of the ecliptic in about 18 years, 224 days, 5 hours.

VIII. To find the inclination of the moon's orbit; obſerve her latitude ſeveral times when ſhe is near a quadrant from her node, and the greateſt latitude is the inclination of her orbit, allowing for the parallax. By obſervation it is found, that the inclination of her orbit is different at different times, but never leſs than 5°, nor greater than 5° 18′.

PROBLEM XVIII. *To find the Refraction of a Star.*

The earth being ſurrounded with a body of air, named the atmoſphere, through which the rays of light paſs to the eye from all the celeſtial bodies; and theſe rays paſſing through a vacuum, and falling obliquely upon the atmoſphere, they will, by the laws of optics, be refracted in lines approaching nearer to the perpendicular of the refracting ſurface.

Therefore, let AD (Plate III. *fig.* 18) be the earth ſurrounded by the atmoſphere, PQR; and let F be a ſtar, whoſe rays paſs through the atmoſphere QA to the obſerver at A.

Now, ſince the atmoſphere is denſer near the earth, and becomes rarer by degrees, as the height increaſes, therefore, at the top, Q, the refraction, is but ſmall; but the nearer a ray approaches the earth, the air being denſer it will be the more refracted, and gradually bent into a curve, QA. By this means the ſtar comes to the eye in the direction GA, which is a tangent to the curve at A; and ſo the ſtar, inſtead of being ſeen at F, where it really is, appears to be at G, ſituated in the line AG.

And ſince the refraction is made in a plane which is perpendicular to the ſurface of the atmoſphere, or to the ſurface of the earth, and which conſequently paſſes through the centre of the earth, therefore, both the true and apparent place, F and G, are in the ſame vertical circle, whoſe plane paſſes through A, the place of the obſerver, and the centre of the earth C.

It is evident alſo, that the refraction will be the ſame at all diſtances from the earth, when the altitude is the ſame, for from whatever part of the line FQ the rays proceed, they will be refracted along the curve QA to A.

Likewiſe we know from the principles of optics, that if a ray of light paſs through ſeveral refracting mediums it will only ſuffer the ſame refraction as if it paſſed immediately out of the firſt into the laſt. Now it has been confirmed by experiments, that light falling upon a medium of air of a mean denſity, and at a very ſmall angle of inclination, will make the refracted angle about 33′. Now to find the refraction at any other altitude, it will by the laws of dioptrics be as radius : coſine 33′ :: coſine of the true altitude of a ſtar : coſine of the apparent altitude by refraction. Then the true altitude, ſubtracted from the apparent altitude, leaves the refracted angle, which is the refraction of the ſtar.

N. B. The refraction will vary a little, as the denſity of the air either increaſes or decreaſes.

To find the refraction by obſervation, take the altitude of a fixed ſtar when it is at the loweſt point under the pole; and again at about 12 hours diſtance, take its altitude when it is at its higheſt, and clear of refraction, or nearly ſo. Then having the latitude of the place, you will find the diſtance of the ſtar from the pole at each obſervation, and by taking the leſs diſtance from the greater, you will have the refraction of the ſtar at the leſs altitude.

In this obſervation a ſtar ſhould be choſen which comes near the zenith, either northward or ſouthward, and ſo its refraction at the greateſt altitude will be inſenſible. If, however, you ſuſpect that it has ſome ſmall refraction when it is at the higheſt, it may be determined thus. As tangent of greater zenith diſtance : tangent of leſs zenith diſtance, :: the refraction at the lower altitude : the refraction at the higher. The lower refraction muſt be corrected, by ſubtracting this from it; and the remainder will be the proper refraction, provided the lower altitude is not leſs than 8° or 10°.

The refraction at 10° altitude is about 5′, and in the horizon from 30′ to 37′.

Note, Refraction makes an object appear higher than it really is, but parallax makes it appear lower. And hence on account of the variableneſs of refraction, it comes to paſs that the top of a mountain may, perhaps, be ſeen in the morning or at night, and be inviſible at noon in the ſame place. Alſo if a teleſcope be placed in a fixed horizontal poſition a whole day, it will ſometimes happen that the ſights will preſent you with the lower part of a tower at one hour of the day, and with the higher part thereof at another hour of the day.

PROBLEM XIX. *To determine the Sun's Parallax and Diſtance.*

This is done by finding firſt the parallax of ſome of the planets, which being known, the ſun's parallax will become known, for the parallaxes of two celeſtial bodies are reciprocally as their diſtances; and the proportional diſtances of the planets from the ſun and from one another are known, and therefore the parallax of one being determined, the parallaxes of the reſt may be determined alſo.

For this purpoſe the planet Mars, when in oppoſition to the ſun, will be the fitteſt to be made uſe of, becauſe at that time he comes neareſt the earth, and his parallax is then the greateſt. The parallax of Mars will be determined by Problem XV.

Mr. Flamſtead found the parallax of Mars leſs than 30″, and thence determines the ſun's parallax not to be above 10″.

PROBLEM XX. *To find the Diſtance of the fixed Stars.*

See Plate III. *Fig.* 19.

Chooſe two ſtars S and D as near together as may be, or if poſſible in one line AST, obſerving alſo to have one a large ſtar and the other a very ſmall one, and that the difference between the longitude of the ſtars, and that of the earth or ſun, be about a quadrant or 90°. Now let ADB be the earth's orbit, and let the earth be ſuppoſed at A, then being furniſhed with as good a teleſcope as can be had, for otherwiſe the attempt will be in vain, obſerve diligently the ſtars S and T, in or near the line AST, and take their diſtance (if it is determinable that they have any) as near as poſſible. And at the diſtance of about half a year, when the earth is in the oppoſite point of its orbit, obſerve the ſame ſtars again, with the ſame inſtrument, which then will appear further diſtant from each other, and will be ſeen under the angle SBT, which muſt be accurately taken. But if you can obſerve no difference between this angle and that of the former obſervation, then the earth has no ſenſible parallax, and therefore no certain concluſions can be drawn.

If a difference can be aſcertained between the angle at A (if any) and the angle at B, that difference will be nearly equal to the parallax of the annual orbit ADB, or ∠ ASB, and hence the ratio of AB to AS will be known.

If the ſtars S and T are taken near the pole of the ecliptic, then in order to find what alteration appears in the two ſtars; obſervations may be made in any two oppoſite points of the ecliptic, or in as many places as ſhall appear requiſite.

If the ſtars are not very different in magnitude, the angles at B and T may be eſtimated by the diſtances BS and ST, and theſe alſo will be expounded by the magnitude of the ſtars. However, theſe angles are ſo exceeding ſmall, that they can ſcarcely be aſcertained by any inſtrument whatever, and hence the aſtoniſhing diſtance of the neareſt fixed ſtars is evident; for if any fixed ſtar, when viewed through a teleſcope that magnifies 100 times, ſhould appear under an angle of half a minute, the true apparent diameter would not exceed 18 thirds, which is leſs than the 6000 part of the ſun's apparent diameter, and therefore ſuppoſing ſuch ſtar to be of the ſame magnitude as the ſun, its diſtance muſt be at leaſt 6000 times more than that of the ſun.

For the following accurate method of determining the parallax of the fixed ſtars, we are beholden to that excellent Aſtronomer Dr. Herſchel.

The doctor firſt premiſes, that the fixed ſtars one with another may well be ſuppoſed to be of a magnitude nearly equal to that of the ſun; and ſecondly, that the difference of their apparent magnitudes is owing to their different diſtances; ſo that the ſtar of the ſecond, third, or fourth magnitude, is two, three, or four times as far off as one of the firſt. Theſe principles which he premiſes as poſtulata, have ſo great a probability in their favour, that they will hardly be objected to by thoſe who are in the leaſt acquainted with the doctrine of chances. Accordingly, let OE, Plate III. *fig.* 20, be the whole diameter of the earth's annual orbit; and let *a*, *b*, *c*, be three ſtars ſituated in the ecliptic, in ſuch a manner that they may be ſeen all in one line O *a*, *b*, *c*, when the earth is at O. Let the line O *a b c*, be perpendicular to OE, and draw PE parallel to *c*O: then, if O *a*, *a b*, *b c*, are equal to each other, *a* will be a ſtar of the firſt magnitude, *b* of the ſecond, and *c* of the third. Let us now ſuppoſe the angle O *a* E, or parallax of the whole orbit of the earth, to be 1′ of a degree; then we have $PEa = OaE = 1''$: and becauſe very ſmall angles, having the ſame ſubtenſe OE, may be taken to be in the inverſe ratio of the lines O *a*, O *b*, O *c*, &c. we ſhall have $ObE = \frac{1}{2}''$, $OcE = \frac{1}{3}''$, &c. Now when the earth is removed to E, we ſhall have $PEb = Ebc = \frac{1}{2}''$, and $PEa - PEb = aEb = \frac{1}{2}''$: i. e. the ſtars *a*, *b*, will appear to be $\frac{1}{2}''$ diſtant. We alſo have $PEc = EcO = \frac{1}{3}''$, and $PEa - PEc = aEc = \frac{2}{3}''$; i. e. the ſtars, *a*, *c*, will appear to be $\frac{2}{3}''$ diſtant when the earth is at E. Now, ſince we have $bEP = \frac{1}{2}''$, and $cEP = \frac{1}{3}''$, therefore $bEP - cEP = bEc = \frac{1}{2}'' - \frac{1}{3}'' = \frac{1}{6}''$; i. e. the ſtars *b*, *c*, will appear to be only $\frac{1}{6}''$ removed from each other when the earth is at E. Whence we may deduce the following expreſſion, to denote the parallax that will become viſible in the change of diſtance between the two ſtars, by the removal of the earth from one extreme of its orbit to the other. Let P expreſs the total parallax of a fixed ſtar of the firſt magnitude, M the magnitude of the largeſt of the two ſtairs, *m* the magnitude of the ſmalleſt, and *p* the partial parallal to be obſerved by the change in the diſtance of a double ſtar; then will $p = \frac{m - M}{Mm}P$; and *p*, being found by obſervation, will give us $P = \frac{pMm}{m - M}$. E. G. Suppoſe a ſtar of the firſt magnitude ſhould have a ſmall ſtar of the twelfth magnitude near it; then will the partial parallax we are to expect to ſee be $\frac{12\times 1P}{12-1}$, or $\frac{11}{12}$ of the total parallax of a fixed ſtar of the firſt magnitude; and if we ſhould, by obſervation, find the partial parallax between two ſuch ſtars to amount to 1″, we ſhall have the total parallax $P = \frac{1\times 1\times 12}{12-1} = 1''.0909$. If the ſtars are of the third and twenty-fourth magnitude, the partial parallax will be $\frac{24-3}{3\times 24} = \frac{21}{72}P$; and if, by obſervation, *p* is found to be a tenth of a ſecond, the whole parallax will come out $\frac{1\times 3\times 24}{24-3} = 0''.3428$.

Farther, ſuppoſe the ſtars being ſtill in the ecliptic, to appear in one line, when the earth is in any other part of its orbit between O and E; then will the parallax ſtill be expreſſed by the ſame algebraic formula, and one of the maxima will ſtill lie at O, the other at E; but the whole effect will be divided into two parts, which will be in proportion to each other as radius — ſine to radius + ſine of the ſtars diſtance from the neareſt conjunction or oppoſition.

When the ſtars are any where out of the ecliptic, ſituated ſo as to appear in one line O *a b c*, perpendicular to O E, the maximum of parallax will ſtill be expreſſed by $\frac{m - M}{Mm}P$; but there will ariſe another addititional parallax in the conjunction and oppoſition, which will be to that which is found 90° before or after the ſun, as the ſine (S) of the latitude of the ſtars ſeen at O is to the radius (R); and the effect of this parallax will be divided into two parts; half of it lying on one ſide of the large ſtar, the other half on the other ſide of it. This latter parallax, moreover, will be compounded with the former, ſo that the diſtance of the ſtars in the conjunction and oppoſition will then be repreſented by the diagonal of a parallelogram, whereof the two ſemiparallaxes are the ſides; a general expreſſion for which will be $\sqrt{\left.\frac{m-P}{2mP}P\right|^{2}\times\frac{SS}{RR}+1}$; for the ſtars will apparently deſcribe two ellipſes in the heavens, whoſe tranſverſe axis will be to each other in the ratio of M to *m* (*fig.* 21), and A *a*, B *b*, C *c*, D *d*, will be the cotemporary ſituations. Now, if *b* Q be drawn parallel to A C, and the parallelogram *b q* B Q be completed, we ſhall have $b\,Q = \frac{1}{2}\,CA - \frac{1}{2}\,ca = \frac{1}{2}\,Cc = \frac{1}{2}\,p$, or ſemiparallax 90° before or after the ſun, and B *b* may be reſolved into, or is compounded of, *b* Q and *b q*; but $b\,q = \frac{1}{2}\,BD - \frac{1}{2}\,bd =$ the ſemiparallax in the conjunction or oppoſition. We alſo have R : S :: *b* Q : $bq = \frac{pS}{2R}$; therefore the diſtance B *b* (or D *d*) $= \sqrt{\overline{\frac{p}{2}}\Big|^2 + \overline{\frac{pS}{2R}}\Big|^2}$; and by ſubſtituting the value of *p* into this expreſſion, we obtain $\sqrt{\overline{\frac{m-M}{2Mm}P}\Big|^2 \times \frac{SS}{RR} + 1}$, as above. When the ſtars are in the pole of the ecliptic, *b q* will become equal to *b* Q, and B *b* will be $7071\ P\,\frac{m-M}{Mm}$. Again, let the ſtars be at ſome diſtance, *e. g.* 5″ from each other, and let them both be in the ecliptic. This caſe is reſolvable into the firſt; for imagine the ſtar *a* (*fig.* 22.) to ſtand at *x*, and in that ſituation the ſtars *x*, *b*, *c*, will be in one line, and their parallax expreſſed by $\frac{m-M}{Mm}P$. But the angle *a* E *x* may be taken to equal to *a* O *x*; and as the foregoing formula gives us the angles *x* E *b*, *x* E *c*, we are to add *a* E *x* or 5′ to *x* E *b*, and we ſhall have *a* E *b*. In general, let the diſtance of the ſtars be *d*, and let the obſerved diſtance at E be D, then will $D = d + p$, and the whole parallax of the annual orbit will be expreſſed by $\frac{DMm - dMm}{m-M} = P$.

Suppoſe the two ſtars now to differ only in latitude, one being in the ecliptic, the other, *e. g.* 5′ north, when ſeen at O. This caſe may alſo be reſolved by the former; for imagine the ſtars, *b*, *c*, (*fig.* 23.) to be elevated at right angles above the plane of the figure, ſo that *a* O *b*, or *a* O *c*, may make an angle of 5″ at O; then, inſtead of the lines O *a b c*, E *a*, E *b*, E *c*, E P, imagine them all to be planes at right angles to the figure; and it will appear that the parallax of the ſtars in longitude muſt be the ſame as if the ſmall ſtar had been without latitude. And ſince the ſtars *b*, *c*, by the motion of the earth from O to E, will not change their latitude, we ſhall have the following conſtruction for finding the diſtance of the ſtars *a b*, *a c*, at E, and from thence the parallax P. Let the triangle *a b* β (*fig.* 24.) repreſent the ſituation of the ſtars; *ab* is the ſubtenſe of 5′, the angle under which they are ſuppoſed to be ſeen at O. The quantity *b*β by the former theorem is found, $\frac{m-M}{Mm}P$, which is the partial parallax that would have been ſeen by the earth's moving from O to E, if both ſtars had been in the ecliptic; but on account of the difference in latitude, it will be now repreſented by *a*β, the hypotheneuſe of the triangle *ab*β: therefore, in general, putting $ab = d$, and $a\beta = D$, we have $\sqrt{\frac{\overline{DD - dd} \times Mm}{m-M}} = P$. Hence D being taken by obſervation, and *d*, M, and *m*, given, we obtain the total parallax.

If the ſituation of the ſtars differs in longitude as well as latitude, we may reſolve this caſe by the following method. Let the triangle *ab*β (*fig.* 25.) repreſent the ſituation of the ſtars, $ab = d$ being their diſtance ſeen at O, $a\beta = D$, their diſtance ſeen at E. That the change *b*β, which is produced by the earth's motion will be truly expreſſed by $\frac{m-M}{Mm}P$ may be proved as before, by ſuppoſing the ſtar *a* to have been placed at α. Now let the angle of poſition *b a* α be taken by a micrometer, or by any other method ſufficiently exact; then, by ſolving the triangle *ab*α, we ſhall have the longitudinal and latitudinal differences *a*α and *b*α of the two ſtars. Put $a\alpha = x$, $b\alpha = y$, and it will be $x + b\beta = \alpha q$, whence $D = \sqrt{\overline{x + \frac{m-M}{Mm}P}\Big|^2 + yy}$; and $\sqrt{\frac{\overline{D^2 - y^2} \times M^2 m - xMm}{m-M}} = P$.

If neither of the ſtars ſhould be in the ecliptic, nor have the ſame longitude or latitude, the laſt theorem will ſtill ſerve to calculate the total parallax whoſe maximum will lie in E. There will, moreover, ariſe another parallax, whoſe maximum will be in the conjunction and oppoſition, which will be divided, and lie on different ſides of the large ſtar; but as we know the whole parallax to be exceedingly ſmall, it will not be neceſſary to inveſtigate every particular caſe of this kind; for by reaſon of the diviſion of the parallax, which renders obſervations taken at any other time, except where it is greateſt, very unfavourable, the formulæ would be of little uſe.

SECT. VIII.

A MORE PARTICULAR DESCRIPTION OF THE PLANETS, &c.

Mercury is a ſmall ſtar, but emits a very bright white light; though on account of his keeping always near the ſun he is ſeldom to be ſeen, and when he does appear, his motion towards the ſun is ſo very ſwift, that he can only be diſcerned for a ſhort time. He appears a little after ſun-ſet; and again a little before ſun-riſe. When this planet is viewed through a good teleſcope he appears equally luminous throughout his whole ſurface. He has different phaſes like the moon, being ſometimes horned, ſometimes gibbous, and ſometimes ſhining almoſt with a round face, though not entirely full, becauſe his enlightened ſide is never turned directly towards us; however at all times he appears bright and well defined, and without a ragged edge.

The diameter of Mercury is computed at about .367 of the Earth's diameters, and its mean diſtance from the ſun at about .3871 of the Earth's diſtance from him; alſo at a mean rate it makes a revolution through its orbit, to the ſame point of the ecliptic, in 87 days, 23 hours, 14 minutes, 34 ſeconds; the inclination of its orbit to the plane of the ecliptic, is 6° 59′ 20″; but the inclination of the axis of Mercury to the axis of the ecliptic is not determined.

Its apparent diameter at a mean diſtance from the earth is 20″, which is about 1″ leſs than it would appear if ſeen from the ſun, the place of its aſcending node at the beginning of the preſent year, 1789 (according to Doctor Halley's tables) is 16° 1′ 30″ in ♉; and of its aphelion 14° 1′ 24″ ♐. The nodes of this planet move forward 50″ per year, and the place of the aphelion moves in like manner 52″ 34‴ per year.

Alſo ſuppoſing the ſemi-tranſverſe diameter of its orbit to be 1, its eccentricity is .20589.

Venus is the moſt beautiful ſtar in the firmament, and is known by the names of the morning and evening ſtar; ſhe likewiſe keeps near the ſun, though ſhe recedes from him almoſt double the diſtance of Mercury. She is never ſeen in the eaſtern quarter of the heavens, when the Sun is in the weſtern; but always ſeems to attend him in the evening, or to give notice of his approach in the morning. This planet alſo has the like phaſes as the moon.

Some aſtronomers have thought that they have ſeen a Satellite moving round Venus, particularly Mr. Montaigne on the 3d and 11th May 1761, who from the obſervations that he made, concluded that its ſynodic revolution was about 12 days. But nothing further has been diſcovered to confirm this matter; and it is generally thought that Mr. Montaigne was miſtaken.

Mr. Dunn of Chelſea, and other gentlemen, in obſerving the tranſit of Venus in A. D. 1761, ſaw a penumbra or ſmall diminution of light, which grew darker and darker for the ſpace of about 5 ſeconds before the internal contact preceding the egreſs; and from thence Mr. Dunn concluded, that Venus is ſurrounded with an atmoſphere of about 50 Geographical miles high.

The diameter of Venus is eſtimated at 1.0275 of the earth's diameter, and its mean diſtance from the ſun at .72333 of the earth's diſtance from the ſun; alſo it turns round its axis in 23 hours and 20 minutes, and makes a revolution in its orbit to the ſame point of the ecliptic in 224 days, 16 hours, 41 minutes, 30 ſeconds. The inclination of its axis to the axis of the ecliptic is about 75° and its orbit to the plane of the ecliptic 2° 23′ 5″.

It is apparent diameter at a mean diſtance from the earth is 1′ 20″, and as viewed from the ſun at a mean diſtance 30″. Alſo the eccentricity of its orbit is .0069813 parts of its ſemi-tranſverſe axis.

The place of its node from the equinox, at the commencement of the preſent year (1789) 14° 43′ 52″ ♊, and of its aphelion 7° 55′ 15″ ♒. The nodes move forward 31″ per year.

OF THE EARTH.

The Earth, or planet which we inhabit, is about 7940 miles in diameter, and, at a mean rate, about 81 millions of miles diſtance from the ſun. It performs a revolution through its orbit to the ſame point of the ecliptic in 365 days, 5 hours, 48 minutes, 57 ſeconds, and revolves round its axis in 23 hours, 56 minutes, 4 ſeconds.

Sir Iſaac Newton, from philoſophical principles, demonſtrated that the figure of the Earth could not be that of a perfect ſphere, but that its equatorial diameter is to its diameter from pole to pole as 230 to 229, which has likewiſe been confirmed by experiments.

The eccentricity of the Earth's orbit is .0168 parts of the ſemi-tranſverſe axis, and the inclination of its axis to the plane of its orbit is 23° 28′. Its apparent diameter, as ſeen from the ſun, is about 21″, and the place of its aphelion, at the commencement of the preſent year, (according to Dr. Halley) is ♑ 9° 8′ 9″, which moves forwards 1º 23′ 20″ in 100 years.

OF THE MOON.

The Earth has one Satellite, namely, the Moon, revolving in an orbit at the diſtance of about 60 of the earth's ſemi-diameters. The diameter of the Moon to that of the earth is as .274 to 1.

The Moon performs a revolution to the ſame point of the ecliptic in 27 days, 7 hours, 43 minutes, 5 ſeconds: in which time alſo ſhe makes a rotation round her axis, the time of her ſynodic revolution, or the mean perion between New Moon and New Moon, is 29 days, 12 hours, 44 minutes, 3 ſeconds, the apparent diameter of the Moon at a mean diſtance from the earth, is 31′ 16½″, and as viewed from the ſun at a mean diſtance 6″.

The inclination of her axis to the axis of the ecliptic is about 2° 10′, and of her orbit to the ecliptic, from 5° to 5° 18′; the mean eccentricity of her orbit is .055, the greateſt .0667, and the leaſt .0433 parts of the ſemi-tranſverſe axis.

The greateſt equation of the Moon's apogee is 12° 18′, and of her node, 1° 29′ 40″. Her mean horizontal parallax is 57′ 5″, and the ratio of the moon's parallax to her diameter, is as 167 to 90.

That there are many inequalities in the Moon's ſurface is allowed by all; ſome of which, it is ſuppoſed, are deep cavities and others, prominences or mountains.

Many aſtronomers have attempted to aſcertain the heights of the lunar mountains, but their concluſions have differed ſo much from each other as muſt prevent any reliance on what they have done. The method, however, purſued by Dr. Herſchel in this buſineſs, is by far the moſt ſcientific and mathematical, and, allowing the caſe to be poſſible, it bids the faireſt to come at truth.

His method ſuppoſes the obſervations to be made when the Moon is not in her quadratures, and is as follows: (ſee Plate III. *fig.* 26.

"Let SLM, ſays he, or *slm*, be a line drawn from the ſun to the mountain, touching the Moon at L or *l*, and the mountain at M or *m*. Then, to an obſerver at E or *e*, the lines L M, *l m*, will not appear of the ſame length, though the mountains ſhould be of an equal height; for L M will be projected into *o n*, and *l m* into O N. But theſe are the quantities that are taken by the micrometer when we obſerve a mountain to project from the line of illumination.

From the obſerved quantity *o n*, when the Moon is not in her quadrature, to find L M, we have the following analogy:

The triangles *o* O L, *r* M L, are ſimilar; therefore, L *o* : L O :: L *r* : L M, or $\frac{LO \times on}{Lo} = LM$: but L O is the radius of the Moon, and L *r* or *o n* is the obſerved diſtance of the mountain's projection; and L *o* is the ſine of the angle ROL $=$ *o*LS; which we may take to be the diſtance of the ſun from the moon without any material error, and which therefore we may find at any given time from an ephemeris.

"The teleſcope uſed in theſe obſervations was a Newtonian reflector, of ſix feet eight inches focal length, to which a micrometer was adopted, conſiſting of two parallel hairs, one of which was moveable by means of a fine ſcrew. The value of the parts ſhown by the index was determined by a trigonometrical obſervation of a known object at a known diſtance, and was verified by ſeveral trials. The power was always 222, excepting where another is expreſsly mentioned; and this was alſo determined by experiment, which frequently differs from theory on account of ſome ſmall errors in the data, hardly to be avoided. The moon having ſufficient light, an aperture of no more than four inches was made uſe of; and, ſays Dr. Herſchel, I believe, that, for diſtinctneſs of viſion, this inſtrument is perhaps equal to any that ever was made."

With this inſtrument he obſerved a prominence, which he calls a rock, ſituated near the Lacus Niger of Hevelius, and found that it projected 41.56″. To reduce this into miles, put R for the ſemidiameter of the moon in ſeconds, as given by the nautical almanack at the time of obſervation, and Q for the obſerved quantity, alſo in ſeconds andounteſimals; then it will be in general, R : 1090 (the moon's ſemidiameter in miles) :: Q : $\frac{1090\,Q}{R} = on$ in miles. Thus it is found, that 41.56″ is 46.79 miles. The diſtance of the ſun from the moon at that time was, by the nautical almanack, about 93° 57½′; the ſine of which to the radius 1 is .9985, &c. $\frac{on}{Lo}$ in this caſe is LM $=$ 46.85 miles.

Then, $\sqrt{\overline{46.85}|^{2} + \overline{1090}|^{2}} = 1091$ miles $=$ OM; and 1091 $-$ 1090 $=$ 1 mile $=$ MP, the height of the mountain.

As the moon has on its ſurface mountains and vallies, in common with the earth, ſome modern aſtronomers have diſcovered a ſtill greater ſimilarity, viz. that ſome of theſe are volcanoes, emitting fire as thoſe on earth do.

Dr. Herſchell has particularly obſerved ſeveral eruptions of the lunar volcanoes, the laſt of which he gives an account of in the Philoſophical Tranſactions for 1787.

"April 19, 10 h. 36′ ſidereal time. I perceive (ſays he) three volcanoes in different places of the dark part of the new moon. Two of them are either already nearly extinct, or otherwiſe in a ſtate of going to break out; which perhaps may be decided next lunation. The third ſhews an actual eruption of fire or luminous matter. I meaſured the diſtance of the crater from the northern limb of the moon, and found it 3′ 57.3″; its light is much brighter than the nucleus of the comet which M. Mechain diſcovered at Paris the 10th of this month.

"April 20, 10 h. 2′, ſidereal time. The volcano burns with greater violence than laſt night. Its diameter cannot be leſs than 3″, by comparing it with that of the Georgian planet: as Jupiter was near at hand, I turned the teleſcope to his third ſatellite, and eſtimated the diameter of the burning part of the volcano to be equal to at leaſt twice that of the ſatellite; whence we may compute, that the ſhining or burning matter muſt be above three miles in diameter. It is of an irregular round figure, and very ſharply defined on the edges. The other two volcanoes are much farther towards the centre of the moon, and reſemble large, pretty faint nebulæ, that are gradually much brighter in the middle; but no well-defined luminous ſpot can be diſcerned in them. Theſe three ſpots are plainly to be diſtinguiſhed from the reſt of the marks upon the moon; for the reflection of the ſun's rays from the earth is, in its preſent ſituation, ſufficiently bright, with a ten-feet reflector, to ſhew the moon's ſpots, even the darkeſt of them; nor did I perceive any ſimilar phænomena laſt lunation, though I then viewed the ſame places with the ſame inſtrument.

"The appearance of what I have called the *actual fire*, or eruption of a volcano, exactly reſembled a ſmall piece of burning charcoal when it is covered by a very thin coat of white aſhes, which frequently adhere to it when it has been ſome time ignited; and it had a degree of brightneſs about as ſtrong as that with which ſuch a coal would be ſeen to glow in faint daylight.

"All the adjacent parts of the volcanic mountain ſeemed to be faintly illuminated by the eruption, and were gradually more obſcure as they lay at a greater diſtance from the crater. This eruption reſembled much that which I ſaw on the 4th of May, in the year 1783, but differed conſiderably in magnitude and brightneſs; for the volcano of the year 1783, though much brighter than that which is now burning, was not nearly ſo large in the dimenſions of its eruption: the former ſeen in the teleſcope reſembled a ſtar of the fourth magnitude as it appears to the naked eye; this, on the contrary, ſhews a viſible diſk of luminous matter, very different from the ſparkling brightneſs of ſtar-light."

OF MARS.

Mars is of a red fiery colour, and always gives a much duller light than Venus, though ſometimes he equals her in ſize. He is not ſubject to the ſame limitations in his motions as Mercury or Venus, but appears ſometimes very near the ſun, and at other times at a great diſtance from him.

The diameter of Mars is to that of the earth as .5229 to 1, and its mean diſtance from the ſun is 152369 of ſuch parts as the diſtance of the earth from the ſun contain 100000; and the eccentricity of its orbit is .09263936 parts of the ſemidiameter. Its apparent diameter, as viewed at a mean diſtance from the earth, is 30″, and as ſeen from the ſun 12″. It makes a rotation round its axis in about 24 hours, 40 minutes, and performs a revolution through its orbit to the ſame point of the ecliptic in one common year, 321 days, 22 hours, 18 minutes, 19 ſeconds: alſo its ſynodic revolution, or time of returning to the ſame fixed ſtar, is 1 year, 321 days, 23 hours, 29 minutes, and 2 ſeconds.

The inclination of the axis of Mars, with reſpect to its own orbit, is about 61° 18′; and conſequently the obliquity of the ecliptic is 28° 42′; the place of the node of the axis is in 19° 28′ ♓: alſo, the inclination of its orbit to the ecliptic is 1° 51′; the place of its aphelion ♍ 1° 18′; and of its node ♉ 21° 4′. Its aphelion moves forward 1° 56′ 40″, in 100 years, and its node 1° 3′ 20″ in 100 years.

From the beſt obſervations the form of Mars is that of a ſpheroid, its equatorial diameter being to its polar diameter in the proportion of about 131 to 127; and there is little doubt but the forms of all the planets are ſpheroids, at leaſt if they may be all ſuppoſed to revolve round their axis, as a motion of that kind cannot be thought to fail of producing ſuch effects: for it was on this principle that Sir Iſaac Newton determined the figure of the earth, and the ratio of equatorial and polar diameters, which has ſince been confirmed by actual menſuration.

It has been commonly related by aſtronomers, that the atmoſphere of this planet is poſſeſſed of ſuch ſtrong refractive powers, as to render the ſmall fixed ſtars near which it paſſes inviſible. Dr. Smith relates an obſervation of Caſſini, where a ſtar in the water of Aquarius, at the diſtance of ſix minutes from the diſk of Mars, became ſo faint before its occultation, that it could not be ſeen by the naked eye, nor with a three-feet teleſcope. This would indicate an atmoſphere of very extraordinary ſize and denſity; but the obſervations of Dr. Herſchel ſhow, that it is of much ſmaller dimenſions: however, after relating what obſervations he has made, he concludes, "that this planet is not without a conſiderable atmoſphere; for, beſides the permanent ſpots on its ſurface, he has often noticed occaſional changes of partial bright belts, and alſo, once a darkiſh one in a pretty high latitude; and theſe alterations can hardly be aſcribed to any other cauſe than the variable diſpoſition of clouds and vapours floating in the atmoſphere of the planet."

OF JUPITER.

Jupiter often appears at a great diſtance from the ſun, and ſhines with a bright white light, and has the ſame general appearance with Mars, only that the belts on his ſurface are much larger, and more permanent; but they are not to be obſerved without an excellent teleſcope. Fontana and two other Italians are ſaid to be the firſt who diſcovered them; but Caſſini was the firſt who gave any tolerable account of them.

Their number is very variable, as ſometimes only one, and at others no fewer than eight, may be perceived. They are generally parallel to one another, but not always ſo; and their breadth is likewiſe variable, one belt having been obſerved to grow narrow, while another in its neighbourhood has increaſed in breadth, as if the one had flowed into the other.

The time of their continuance is very uncertain, ſometimes remaining unchanged for three months; at others, new belts have been formed in an hour or two. In ſome of theſe belts large black ſpots have appeared, which moved ſwiftly over the diſk from eaſt to weſt, and returned in a ſhort time to the ſame place; from whence the rotation of this planet about its axis has been determined.

The time of its rotation is about 9 h. 56 min. and it makes a revolution in its orbit to the ſame point of the ecliptic in 11 years, 313 days, 8 hours, 35 minutes, 4 ſeconds; and the time of its ſynodic revolution is 4332 days, 12 hours, 20 min. 9 ſeconds.

Its apparent diameter, as ſeen at a mean diſtance from the earth, is 39″, and as viewed from the ſun 37″: its real diameter is 9.1468 of the earth's diameter. The denſity of this planet is to that of the earth as .23625 to 1. The proportion of light and heat on its ſurface, to that on the earth, is as .0369 to 1, and the ratio of its polar and equatorial diameters are as 12 to 13. The eccentricity of its orbit is .0482192 parts of its ſemi-tranſverſe axis; its mean diſtance from the ſun 520096 of ſuch parts, as the earth's diſtance contains 100000.

The place of its aphelion at the commencement of the preſent year was ♎ 11° 20′ 36″, and of its node ♋ 8° 48′ 20″. Alſo, its aphelion moves forwards 2° in 100 years, and its node moves 1° 23′ 20″ in 100 years.

The inclination of the axis of Jupiter to the ecliptic is undetermined, but the inclination of his orbit to that of the ecliptic is 2° 33½′. It is, however, ſaid, that the plane of his equator is nearly coincident with that of his orbit; and if ſo, there can be very little difference of ſeaſons on Jupiter's ſurface.

OF JUPITER's SATELLITES.

The moſt remarkable circumſtance attending Jupiter, is his having four moons, which conſtantly revolve round him at different diſtances. Theſe are all ſuppoſed to move in ellipſes; though the eccentricities of all of them are too ſmall to be meaſured, excepting that of the fourth; and even this amounts to no more than 0.007 of its mean diſtance from the primary. The orbits of theſe ſecondary planets were thought by Galileo to be in the ſame plane with that of their primary: but Mr. Caſſini found that their orbits make a ſmall angle with it; and that their nodes are nearly in the ſame plane.

The firſt of theſe ſatellites revolves at the diſtance of 5.697 of Jupiter's ſemidiameters, or 1′ 51″ as meaſured by proper inſtruments; its periodical time is 1 d. 18 h. 27′ 34″. The next ſatellite revolves at the diſtance of 9.017 ſemidiameters, or 2′ 56″, in 3 d. 13 h. 13′ 42″; the third at the diſtance of 14.384 ſemidiameters, or 4′ 42″, in 7 d. 3 h. 42′ 36″; and the fourth at the diſtance of 25.266, or 8′ 16″, in 16 d. 16 h. 32′ 09″.

When a ſatellite is in its ſuperior ſemicircle, or that half of its orbit which is more diſtant from the earth than Jupiter is, its motion appears to us direct, according to the order of the ſigns; but in its inferior ſemicircle, when it is nearer to us than Jupiter, its motion appears retrograde; and both theſe motions ſeem quicker the nearer the ſatellites are to the centre of the primary, ſlower the more diſtant they are, and at the greateſt diſtance of all they appear for a ſhort time to be ſtationary.

From this account of the ſyſtem of Jupiter and his ſatellites, it is evident, that occultations of them muſt frequently happen by their going behind their primary, or by coming in betwixt us and it. The former takes place when they proceed towards the middle of their upper ſemicircle; the latter, when they paſs through the ſame part of their inferior ſemicircle. Occultations of the former kind happen to the firſt and ſecond ſatellite; at every revolution, the third very rarely eſcapes an occultation, but the fourth more frequently by reaſon of its greater diſtance. It is ſeldom that a ſatellite can be diſcovered upon the diſk of Jupiter, even by the beſt teleſcopes, excepting at its firſt entrance, when by reaſon of its being more directly illuminated by the rays of the ſun than the planet itſelf, it appears like a lucid ſpot upon it. Sometimes, however, a ſatellite in paſſing over the diſk, appears like a dark ſpot, and is eaſily to be diſtinguiſhed. This is ſuppoſed to be owing to ſpots on the body of the ſecondary planets; and it is remarkable, that the ſame ſatellite has been known to paſs over the diſk at one time as a dark ſpot, and at another ſo luminous that it could not be diſtinguiſhed from Jupiter himſelf, except at its coming on and going off. To account for this, we muſt ſay, that either the ſpots are ſubject to change; or if they be permanent, like thoſe of our moon, that the ſatellites at different times turn different parts of their globes towards us. Poſſibly both theſe cauſes may contribute to produce the phænomena juſt mentioned.

When the ſatellites paſs through their inferior ſemicircles, they may caſt a ſhadow upon their primary, and thus cauſe an eclipſe of the ſun to his inhabitants if there are any; and in ſome ſituations this ſhadow may be obſerved going before or following the ſatellite. On the other hand, in paſſing through their ſuperior ſemicircles, the ſatellites may be eclipſed in the ſame manner as our moon by paſſing through the ſhadow of Jupiter: and this is actually the caſe with the firſt, ſecond, and third of theſe bodies; but the fourth, by reaſon of the largeneſs of its orbit, paſſes ſometimes above or below the ſhadow, as is the caſe with our moon. The beginnings and endings of theſe eclipſes are eaſily ſeen by a teleſcope when the earth is in a proper ſituation with regard to Jupiter and the ſun; but when this or any other planet is in conjunction with the ſun, the ſuperior brightneſs of that luminary renders both it and the ſatellites inviſible. From the time of its firſt appearing after a conjunction until near the oppoſition, only the immerſions of the ſatellites into his ſhadow, or the beginnings of the eclipſes, are viſible; at the oppoſition, only the occultations of the ſatellites, by going behind or coming before their primary, are obſervable; and from the oppoſition to the conjunction, only the emerſions, or end of the eclipſes, are to be ſeen. This is exactly true in the firſt ſatellite, of which we can never ſee an immerſion with its immediately ſubſequent emerſion: and it is but rarely that they can be both ſeen in the ſecond; as in order to their being ſo, that ſatellite muſt be near one of its limits, at the ſame time that the planet is near his perihelion and quadrature with the ſun. With regard to the third, when Jupiter is more than 46 degrees from conjunction with, or oppoſition to, the ſun, both its immerſions and immediately ſubſequent emerſions are viſible; as they likewiſe are in the fourth, when the diſtance of Jupiter from conjunction or oppoſition is 24 degrees.

OF SATURN.

Saturn is alſo frequently ſeen at a great diſtance from the ſun, and ſhines with a pale faint light, and when viewed through a good teleſcope makes a more remarkable appearance than any of the other planets.

Galileo firſt diſcovered his uncommon ſhape, which he thought to be like two ſmall globes, one on each ſide of a large one: and he publiſhed his diſcovery in a Latin ſentence; the meaning of which was, that he had ſeen him appear with three bodies; though, in order to keep the diſcovery a ſecret, the letters were tranſpoſed. Having viewed him for two years, he was ſurpriſed to ſee him become quite round without theſe appendages, and then after ſome time to aſſume them as before. Theſe adjoining globes were what are now called the *anſæ* of his ring, the true ſhape of which was firſt diſcovered by Huygens about 40 years after Galileo. From the diſcoveries made by him and other aſtronomers, it appears that this planet is ſurrounded by a broad thin ring, the edge of which reflects little or none of the ſun's light to us, but the planes of the ring reflect the light in the ſame manner that the planet itſelf does; and if we ſuppoſe the diameter of Saturn to be divided into three equal parts, the diameter of the ring is about ſeven of theſe parts. The ring is detached from the body of Saturn in ſuch a manner, that the diſtance between the innermoſt part of the ring and the body is equal to its breadth. Being commonly viewed at an oblique angle, appears of an oval form, and through very good teleſcopes double, as repreſented Plate III. *Fig.* 27. Both the outward and inward rim is projected into an illipſis, more or leſs oblong according to the different degrees of obliquity with which it is viewed. Sometimes our eye is in the plane of the ring, and then it becomes inviſible; either becauſe the outward edge is not fitted to reflect the ſun's light, or more probably becauſe it is too thin to be ſeen at ſuch a diſtance. As the plane of this ring keeps always parallel to itſelf, that is, its ſituation in one part of the orbit is always parallel to that in any other part, it diſappears twice in every revolution of the planet, that is, about once in 15 years; and he ſometimes appears quite round for nine months together. At other times, the diſtance betwixt the body of the planet and the ring is very perceptible.

When Saturn appears round, if our eye be in the plane of the ring, it will appear as a dark line acroſs the middle of the planet's diſk; and if our eye be elevated above the plane of the ring, a ſhadowy belt will be viſible, cauſed by the ſhadow of the ring, as well as by the interpoſition of part of it betwixt the eye and the planet. When it appears double, the ring next the body of the planet appears brighteſt. He has alſo two belts, diſcovered with very long teleſcopes, which appear parallel to that formed by the edge of the ring abovementioned; but theſe are rectilinear when the ring appears elliptic, and ſeem to be permanent. In 1683, however, Dom. Caſſini and Fatio perceived a bright ſtreak upon Saturn, which was not permanent like the dark belts, but was viſible one day, and diſappeared the next, when another came into view near the edge of his diſk. This induced Caſſini to ſuppoſe, that Saturn might have a rotation round his axis; but the diſtance of this planet is ſo great, that we can ſcarce hope to determine his revolution ſo accurately as that of the others.

The aſtronomer-royal, Dr. Maſkelyne, informs us, the phænomena of diſappearance and reappearance may be expected to take place as follows:

"May 2d, 1789, Saturn's ring will diſappear; the earth being about to paſs from its northern ſide, which is enlightened, to its ſouthern ſide, which is obſcure.

"Auguſt 27th, the earth having repaſſed to the northern or enlightened ſide, the ring will reappear.

"October 8th, the ring will diſappear; its plane being near paſſing through the ſun, when it will change its enlightened ſide from the northern to the ſouthern one, conſequently the dark ſide will be then turned to the earth.

"January 30th, 1790, the earth having paſſed from the northern or dark ſide of the ring, to the ſouthern or enlightened one, the ring will become viſible, to continue ſo until the year 1803."

The diameter of Saturn is to the earth's diameter as 7.2661 to 1.; and its mean diſtance from the ſun 954006 of ſuch parts, as the earth's diſtance contains 100000: alſo the eccentricity of its orbit is .05700322 parts of the ſemi-tranverſe axis.

Its apparent diameter, as ſeen at a mean diſtance from the earth, is 16", which is much about the ſame as when ſeen at a mean diſtance from the ſun. The time of its rotation round its axis, is undetermined. But its periodical revolution to the ſame point of the ecliptic is 10750 days, 13 hours, 14 minutes, 42 ſeconds; and its ſynodic revolution 10759 days, 6 hours, 36 minutes.

The inclination of its orbit to the ecliptic is 2° 33′ ½; but the inclination of its axis to the ecliptic is not determined. The proportion of its light and heat to that of the earth is as .010987 to 1. The place of Saturn's aphelion at the commencement of the preſent year was ♑ 0° 31′, and of its node ♋ 21° 31′ 48″. The aphelion moves forward 2° 13′ 20″ in 100 years, and the node 0° 30′ in the ſame.

THE SATELLITES OF SATURN.

Saturn is ſtill better attended than Jupiter; having, beſides the ring before mentioned, no fewer than five moons continually circulating round him. The firſt at the diſtance of 2.097 ſemidiameters of his ring, and 4.893 of the planet itſelf, performs its revolution in 1 d. 21 h. 18′ 22″; the ſecond, at 2.686 ſemi-diameters of the ring, and 6.268 of Saturn, revolves in 2 days, 17 hours, 41′ 22″; the third, at the diſtance of 8.754 ſemidiameters of Saturn, and 3.752 of the ring, in 4 days, 12 hours, 25′ 12″; the fourth, called the Huygenian Satellite, at 8.698 ſemi-diameters of the ring, and 20.295 of Saturn, revolves in 15 d. 22 h. 4′ 12″; while the fifth, placed at the vaſt diſtance of 59.154 ſemidiameters of Saturn, or 25.348 of his ring, does not perform its revolution in leſs than 79 d. 7 h. 47′. The orbits of all theſe Satellites, except the fifth, are nearly in the ſame plane, which makes an angle with the plane of Saturn's orbit of about 31°; and by reaſon of their being inclined at ſuch large angles, they cannot paſs either acroſs their primary or behind it with reſpect to the earth, except when very near their nodes; ſo that eclipſes of them happen much more ſeldom than of the ſatellites of Jupiter.

THE NEW PLANET, or GEORGIUM SIDUS.

The new Planet, called the Georgium Sidus, was firſt obſerved by Dr. Herſchel on the 13th of March 1781, near the foot of Caſtor, and his attention was drawn by its ſteady light. On applying an high magnifying power to his teleſcope, it appeared manifeſtly to increaſe in diameter; and two days after, he obſerved that its place was changed. From theſe circumſtances he concluded, that it was a comet; and ſent an account of it as ſuch to the aſtronomer-royal, which very ſoon ſpread all over Europe. It was not long, however, before it was known, eſpecially by the Engliſh aſtronomers, to be a planet. The circumſtances which led to this diſcovery were, its vicinity to the ecliptic, the direction of its motion, and its being nearly ſtationary at the time, in ſuch a manner as correſponds with the like appearances of the other planets. The French aſtronomers, however, ſtill imagined it to be a comet, although it had not that faint train of light which uſually accompanies theſe bodies, nor would its ſucceſſive appearances correſpond with ſuch an hypotheſis: ſo that they were at laſt obliged to own that it went round the ſun in an orbit nearly circular. Its motion was firſt computed on this principle by Mr. Lexel profeſſor of aſtronomy at St. Peterſburgh; who ſhowed, that a circular orbit, whoſe radius is about 19 times the diſtance of the earth from the ſun, would agree very well with all the obſervations which had been made during the year 1781. On the 1ſt of December that year it was in oppoſition with the ſun; whence one of its ſtations was certainly determined.

Before the end of the year 1782, it was found, that the angular motion of the planet was increaſing; which ſhowed, that it was not moving in a circle, but in an eccentric orbit, and was approaching towards the ſun. Aſtronomers, therefore, began to inveſtigate the inequality of this angular heliocentric motion, in order to diſcover the form and poſition of the ellipſis deſcribed. This was a very difficult taſk, as the ſmall inequality of motion ſhowed that the orbit was nearly circular, and the arch already deſcribed was no more than one-fiftieth of the whole circumference.

From the obſervations made on this planet in the year 1781, M. De La Lande, calculated its courſe for 1782, and found its diſtance from the ſun to be nineteen times greater than that of the earth, agreeable to the computation of Mr. Lexel. He alſo determined its magnitude to be about eighty-nine times greater than the earth, or its diameter to that of the earth to be as 4.454 to 1; and that it revolves round the ſun in an orbit, which is nearly circular, in about 82 years.

The inclination of its orbit is 43′ 35″, and its apparent diameter only about 4″; ſo that it can ſeldom be ſeen plainly by the naked eye, but may eaſily be diſcovered in a clear night when above the horizon, by a good teleſcope, its ſituation with reſpect to the fixed ſtars being previouſly known.

At the commencement of the preſent year, its heliocentric longitude was ♌ 2½°, and its heliocentric latitude about 36′. Alſo its geocentric longitude was ♌ 4°, and its geocentric latitude 37′. The annual motion of its heliocentric longitude is about 4° 38′.

The light of this planet is of a bluiſh white colour, and its brilliancy between that of the Moon and Venus.

Whether it was attended by any ſatellites, was at firſt only a matter of conjecture, but Dr. Herſchel has ſince diſcovered two; and, from the remote ſituation of the planet, it is probable there are ſeveral others. He has not ſeen them long enough to aſcertain their periodical times with great accuracy, but is led to ſuppoſe that the firſt performs its revolution in about 8¾ days, and the other 13½ days nearly.

As a mark of reſpect to his preſent Majeſty, and to convey to poſterity an idea of the time and place of diſcovery, Dr. Herſchel has diſtinguiſhed this planet by the name of Georgium Sidus.

His Majeſty has ſince taken Dr. Herſchel under his patronage, and granted him an annual ſalary.

OF THE SUN.

The Sun, about which all the planets and comets move, though to human eyes ſo extremely bright and ſplendid, is yet frequently obſerved, even through a teleſcope of but very ſmall powers, to have dark ſpots on his ſurface.

There is great variety in the magnitude of the ſolar ſpots; the difference is chiefly in ſuperficial extent of length and breadth; their depth or thickneſs is very ſmall; ſome have been ſo large as, by computation, to be capable of covering the continents of Aſia and Africa; nay, the whole ſurface of the earth, or even five times the ſurface.

The diameter of a ſpot, when near the middle of the diſk, is meaſured by comparing the time it takes in paſſing over a croſs hair in a teleſcope, with the time wherein the whole diſk of the ſun paſſes over the ſame hair; it may alſo be meaſured by the micrometer; and by either of theſe methods we may judge how many times the diameter of the ſpot is contained in the diameter of the ſun. Spots are ſubject to increaſe and diminution of magnitude, and ſeldom continue in the ſame ſtate. They are of various ſhapes; moſt of them having a deep black nucleus ſurrounded by a duſky cloud, whereof the inner parts near the black are a little brighter than the outſkirts. They change their ſhapes, ſomething in the manner that our clouds do; though not often ſo ſuddenly: thus, what is of a certain figure to-day, ſhall to-morrow, or perhaps in a few hours, be of a different one; what is now but one ſpot, ſhall in a little time be broken into two or three; and ſometimes two or three ſpots ſhall coaleſce, and be united into one.

Dr. Long, many years ſince, while he was viewing the image of the Sun through a teleſcope caſt upon white paper, ſaw one roundiſh ſpot, by eſtimation not much leſs than the diameter of our earth, break into two, which receded from one another with prodigious velocity.

From theſe phænomena it is evident, that the ſpots are not endowed with any permanency, nor are they at all regular in their ſhape, magnitude, number, or in the time of their appearance or continuance. Hevelius obſerved one that aroſe and vaniſhed in 16 or 17 hours; nor has any been obſerved to continue longer than 70 days, which was the duration of one in the year 1676: thoſe ſpots that are formed gradually, are gradually diſſolved; while thoſe that ariſe ſuddenly, are for the moſt part ſuddenly diſſolved. When a ſpot diſappears, that part where it was generally, becomes brighter than the reſt of the ſun, and continues ſo for ſeveral days; on the other hand, thoſe bright parts (called faculæ, as the others are called maculæ) ſometimes turn to ſpots.

The ſolar ſpots appear to have a motion which carries them acroſs the ſun's diſk. Every ſpot, if it continues long enough without being diſſolved, appears to enter the ſun's diſk on the eaſt ſide, to go from thence with a velocity continually increaſing, till it has gone half its way; and then to move ſlower and ſlower, till it goes off at the weſt ſide, after which it diſappears for about the ſame ſpace of time that it ſpent in croſſing the diſk, and then enters upon the eaſt ſide again, nearly in the ſame place, and croſſes it in the ſame tract, and with the ſame unequal motion as before.

This apparent inequality in the motion of the ſpots, is purely optical, and is in ſuch proportion as demonſtrates them to be carried round equally, or in a circle, the plane of which continued, paſſes through or near the eye of a ſpectator upon the earth.

The ſpots are by no means confined to one part of the ſun's diſk; though we have not heard of any being obſerved about his polar regions: and though their direction is from eaſt to weſt, yet the paths they deſcribe in their courſe over the diſk are exceedingly different; ſometimes being ſtrait lines, ſometimes curves, ſometimes deſcending from the northern to the ſouthern part of the diſk, ſometimes aſcending from the ſouthern to the northern.

By obſervations on the ſpots, the ſun is found to move round its axis once in about 25¼ days.

The apparent ſemidiameter of the ſun at a mean diſtance from the earth is 32′ 12″, and his real diameter is to that of the earth as 91.7431 to 1. The inclination of its axis to the axis of the ecliptic is 7°½. And the denſity of the ſun to that of the earth is as 1 to 4. Alſo the proportion of light and heat on the ſurface of the ſun to that on the earth is as 45025 to 1.

THE FIXED STARS.

The fixed ſtars, as was obſerved in Section II. do not belong to this Syſtem, but are probably diſpoſed as ſo many ſuns to other Syſtems. It is certain, that they are not opake bodies as are the planets, but ſhine by their own native luſtre.

Among the fixed ſtars great changes have often been obſerved. Stars of a ſuperior magnitude have by degrees become leſs and leſs, ſo as hardly to be perceptible; and ſome have even vaniſhed, and have never been ſeen more; while others of an inferior ſize have gradually increaſed till they appeared as large as thoſe of the 2d or 3d magnitude, when they have again decreaſed and afterwards increaſed again, and ſo on in regular order.

Theſe phænomena of the ſtars may ariſe from each Syſtem's revolving round its centre of gravity, which Sir Iſaac Newton has demonſtrated muſt be the caſe when one body gravitates round another; for by this means they will at different periods be at different diſtances from us, and ſo appear under unequal magnitudes. However, it muſt be confeſſed, that unleſs the orbits they deſcribed in this way were very conſiderable, it would not materially alter their appearance; for we find their diſtance is ſo immenſe, that when they are obſerved from oppoſite parts of the earth's orbit it produces no ſenſible change. It is probable, therefore, that ſome of theſe phænomena may be effected by dark ſpots ariſing on their ſurface, ſimilar to thoſe on the ſun, which for a time eclipſe their brightneſs, and ſo cauſe them to appear of an inferior magnitude till the ſpots by degrees vaniſh, when they appear again of full ſize.

In order to keep a proper account of the ſtars, Aſtronomers ſuppoſe the heavens to be divided into what they call conſtellations, each containing a certain number of ſtars, of different magnitudes. The conſtellations are 80 in number, viz. 12 in the zodiac, 36 in the northern hemiſphere, and 32 in the ſouthern hemiſphere. The ſtars compoſing each conſtellation are for the eaſe of being remembered, ſuppoſed to form the outlines of ſome animal or figure, and accordingly in the maps of the ſtars we ſee the conſtellations thus repreſented, though the ſtars in moſt of them form very imperfect out-lines of the figures aſcribed to them.

The names of the conſtellations and the number of ſtars of each magnitude, are as follow:

NORTHERN CONSTELLATIONS.

Names.	Number.	Magnitudes.						Names.	Number.	Magnitudes.

The above Tables ſhew the number of what is uſually called the Conſtellation Stars; but, excluſive of thoſe, there are a variety of others diſcoverable by teleſcopes.

Dr. Herſchel, with his improved teleſcope, has diſcovered ſeveral thouſands of Stars which were not obſerved before; ſo that his Catalogue of Stars extends to three or four times the number contained in that given by Mr. Flamſtead.

There is a ſort of Stars named Nebulous Stars, from their appearing like a bright cloud. They are not to be diſtinguiſhed by the naked eye, and, when viewed through a teleſcope, appear as a cluſter of very ſmall Stars. And, indeed, to whatever part of the Heavens a good teleſcope is directed, a number of Stars will appear which are not diſcoverable by the eye alone.

Hence, though it is almoſt demonſtrable that the number of Stars is not infinite, yet it may be reaſonably inferred that there are thouſands, perhaps millions, which cannot be diſcovered, even by means of the beſt teleſcopes whatever; and hence is demonſtrable the infinite wiſdom, omnipotence, and omnipreſence of the Creator of the Univerſe.

It is with pleaſure I acknowledge myſelf indebted to Mr. Moody, for the following Table of Stars. He informs me, that he has carefully adjuſted their Right Aſcenſions, Declinations, &c. to the preſent Time, which renders the Table a valuable Acquiſition to thoſe who enter into the practical Part of Aſtronomy; as it will be found not only an accurate Account of thoſe particular Stars therein mentioned, but will alſo be of uſe to determine the Latitudes of Places on this Globe, by means of the obſerved Altitudes of thoſe Stars taken at particular Times.

T. BANKES.

A TABLE of the Right Ascensions, Declinations, Longitudes, Latitudes, and Magnitudes, of Twenty-one of the principal Fixed Stars, accurately rectified to the Commencement of the preſent Year, 1789.

SECT. IX.

THE ASTRONOMY OF THE SPHERE.

Although the celeſtial bodies are placed at different diſtances from the earth, as has been before ſhewn; yet, an obſerver, living upon the earth, is not naturally ſenſible thereof, but imagines them all to be ſituate in one concave ſurface, of which the earth is the centre.

Likewiſe, though in reality the cauſe of day and night is the rotation of the earth round its own axis; and of the ſeaſons, its motion through its own orbit (or ecliptic) in a year; yet, to a ſpectator on the earth, theſe appear to be effected by the motion of the ſun, or heavens.

And as in moſt Aſtronomical Problems, it is the apparent or relative motions only that we have to determine; therefore, for the eaſe of imagination, and ſince it amounts to one and the ſame thing whether way theſe appearances are effected, Aſtronomers chuſe to ſuppoſe all celeſtial objects placed in one concave ſphere, as above; and to aſcribe to them all the motions which they ſeem to have, while the earth is conſidered as being at reſt.

Definitions.

I. The Aſtronomy of the ſphere is the method of finding (from proper data) the meaſure of certain arcs and angles, formed on the ſurfaces of the celeſtial and terreſtrial ſpheres by the *apparent motions* of the bodies which are ſeen in the heavens.

II. The ſurfaces of thoſe ſpheres are ſuppoſed to be concentric to the centre of the earth, and to have correſpondent circles deſcribed on both ſpheres.

III. Great Circles, are ſuch as divide either ſphere into two equal parts.

IV. Lesser Circles, are thoſe which divide either ſphere into unequal parts.

V. The Poles of a Circle, are thoſe points on the ſphere that are equally diſtant from that circle.

VI. An Axis, is a right line ſuppoſed to connect the poles.

VII. The Celestial Axis, is that right line about which the heavens ſeem to revolve.

VIII. The North and South poles of the world, are thoſe two points where the axis cuts the celeſtial ſphere.

IX. The Equinoctial, in the celeſtial; or Equator, on the terreſtrial ſphere, is that *great circle* which is equally diſtant from the poles of the world.

X. Meridians, or Hour Circles, or Circles of Right Ascension, or Circles of "Terrestrial Longitude," are great circles perpendicular to the equator, and paſſing through the poles of the world.

XI. The Ecliptic is a great circle inclined to the equator in an angle of 23° : 28′, and cutting it in two points diametrically oppoſite. This circle is ſuppoſed to be divided into 12 equal parts, called ſigns, beginning from one of its interſection with the equator; alſo each ſign is ſuppoſed to be divided into 30 equal parts, called degrees; each degree, into 60 minutes; each minute, into 60 ſeconds, &c. and in general every great circle is divided into 360 degrees, and each degree into 60 minutes, &c.

The names and characters of the ſigns of the ecliptic are as under.

Aries,	Taurus,	Gemini;	Cancer,	Leo,	Virgo,
♈	♉	♊	♋	♌	♍;
Libra,	Scorpio,	Sagittarius,	Capricornus,	Aquarius,	Piſces.
♎	♏	♐	♑	♒	♓

The former ſix being on the north ſide of the equinoctial, are called northern ſigns; and the latter ſix, being on the ſouth ſide thereof, are named ſouthern ſigns.

XII. The Cardinal Points of the Ecliptic, are the four firſt points of the ſigns ♈, ♋, ♎, ♑; thoſe of ♈ and ♎ are called Equinoctial Points; and thoſe of ♋ and ♑ are called Solstitial Points.

When the motion in the ecliptic is according to the order of ſigns, as from ♈ to ♉, and from ♉ to ♊, &c. it is ſaid to be forward, or *in conſequentia:* but when the motion is the contrary way, as from ♉ to ♈, from ♈ to ♓, &c. then it is ſaid to be backward, or in *antecedentia*.

Alſo when two planets, &c. are referred to the ſame point of the ecliptic, they are ſaid to be in *conjunction*. When they are referred to oppoſite points, they are ſaid to be in *oppoſition*. If they are 3 ſigns diſtant, they are in *quartile aſpect*; if 4 ſigns diſtant, in a *trine aſpect*. If 2 ſigns apart, in a *ſextile aſpect*. The characters uſed by Aſtronomers for denoting theſe aſpects, are the following ☌, conjunction; ☍, oppoſition; □, quartile; △, trine; and ⚹, ſextile.

The point of the ecliptic, which is riſing at any place, is called the *horoſcope*; the higheſt point of it is named the *nonageſimal degree*. The point in the meridian, is the *medium cœli*, or culminating point; the oppoſite point, the *imum cœli*.

XIII. The Equinoctial Colure is a meridian, paſſing through the equinoctial points.

XIV. The Solstitial Colure is a meridian, paſſing through the ſolſtitial points.

N. B. The colures cut one another at right angles in the poles of the world.

XV. Circles of Celestial Longitude, are great circles perpendicular to the ecliptic.

XVI. The Latitude of any Point in the heavens, is an arc of a circle of longitude intercepted between that point and the ecliptic, and is called north or ſouth latitude, according as the point is on the north or ſouth ſide of the ecliptic.

XVII. Parallels of Celestial Latitude, are ſmall circles parallel to the ecliptic.

XVIII. The Longitude of any Point in the heavens, is an arc of the ecliptic intercepted between the firſt point of Aries, and a circle of longitude paſſing through that point.

XIX. The Right Ascension of any Point of the celeſtial ſphere, is an arc of the equator contained between the firſt point of Aries, and a meridian paſſing through that point; or it is the angle formed by the equinoctial colure, and the meridian paſſing over that point.

XX. The Declination of any Point is an arc of the meridian, contained between that point and the equinoctial. If the point is on the north ſide of the equinoctial, it is called north declination; but, if it is on the ſouth ſide thereof, it is called ſouth declination.

XXI. The Obliquity of the Ecliptic is the angle made by the interſection of the equator and ecliptic, and is meaſured by the ſun's greateſt declination, which according to modern obſervations is about 23° : 28′.

XXII. Parallels of Declination are ſmall circles, parallel to the equinoctial.

The Tropic of Cancer is a parallel of declination in the northern hemiſphere, diſtant 23° : 28′ from the equinoctial; and the Tropic of Capricorn is a parallel of declination in the ſouthern hemiſphere, and at the like diſtance from the equinoctial. Alſo the Artic Polar Circle is a parallel of declination at 23° : 28′ diſtance from the North pole; and the Antartic Polar Circle is a parallel of declination, as far diſtant from the ſouth pole.

XXIII. The Zenith is that point of the heavens directly over a place.

XXIV. The Nadir is that point of the ſphere, which is directly under a place.

XXV. The Horizon is that great circle of the ſphere, which is equally diſtant from the Zenith and Nadir of any place, and divides the ſphere into the upper and lower hemiſpheres.

XXVI. The Rising of a celeſtial object, is when its centre appears in the eaſtern part of the horizon.

XXVII. The Setting of a celeſtial body, is when its centre diſappears in the weſtern quarters of the horizon.

XXVIII. Azimuths, or Vertical Circles, are great circles perpendicular to the horizon, paſſing through the Zenith and Nadir.

XXIX. The Prime Vertical, is that vertical circle which paſſes through the eaſt and weſt points of the horizon, and is at right angles to the *Meridian of the Place*, which is a vertical circle paſſing through the north and ſouth points of the horizon.

XXX. The Azimuth of any celeſtial object, is an angle at the Zenith formed by the meridian of any place, and a vertical circle paſſing through that object when it is above the horizon; or, it is meaſured by the arc of the horizon intercepted between thoſe vertical circles.

XXXI. The Amplitude of any Point in the heavens, is an arc of the horizon contained between that point at his riſing or ſetting, and the interſection of the meridian of the place with the horizon; or, it is the angle at the zenith included between the meridian of a place and a vertical circle, paſſing through the point at its riſing or ſetting.

XXXII. The Altitude of any Point in the heavens, is an arc of a vertical circle, intercepted between that point and the horizon.

XXXIII. The Zenith Distance of any object, is an arc of a vertical circle contained between that point and the zenith.

N. B. The altitude and zenith diſtance are complements of one another.

XXXIV. The Meridian Altitude, or Meridian Zenith Distance, is the altitude, or zenith diſtance, when the object is on the meridian of a place.

XXXV. The Culminating of any celeſtial object is the time it tranſits, or comes to the meridian.

XXXVI. Almincanthers, or Parallels of Altitude, are ſmall circles parallel to the horizon.

XXXVII. A Parallel Sphere, is that poſition of the ſphere wherein the circles apparently deſcribed by the diurnal rotation, are parallel to the horizon; which can happen only at the Poles.

XXXVIII. A Right Sphere, is that when the diurnal motions are at right angles to the horizon. This is the caſe with all places on the equator.

XXXIX. An Oblique Sphere, has all the diurnal motions oblique to the horizon. And thus the motions appear to all parts of the earth, except under the poles, and on the equator.

XL. Diurnal Arcs, are thoſe parts of the parallels of declination of celeſtial objects, apparently deſcribed between the times of the riſing and ſetting of thoſe objects.

XLI. Nocturnal Arcs, are the parts of thoſe parallels apparently deſcribed from the time of ſetting to the time of riſing.

N. B. Semi-diurnal and Semi-nocturnal Arcs, are the parts of the parallels between the meridian and their interſection with the horizon. The correſponding part of the equator anſwering to the ſemi-diurnal arc, gives the time between noon and the riſing or ſetting; and the equatorial part anſwering to the ſemi-nocturnal arc, ſhews the time between midnight and the time of riſing or ſetting.

XLII. The Oblique Ascension of any point in the heavens is the degree of the equator, which riſes with that *point* in an *oblique ſphere.*

XLIII. The **Oblique Descension** of any point in the heavens is the degree of the equator, which ſets with that point in an oblique ſphere.

XLIV. The **Ascensional Difference** belonging to any celeſtial object, is the difference between its *right* and *oblique aſcenſions.* In the ſun, it is the time that he riſes or ſets before or after the hour of ſix.

XLV. The **Latitude** of any place on the earth, is an arc of a terreſtrial meridian contained between that place and the equator; being called North or South latitude, according as it is on the North or South ſide of the equator.

XLVI. The **Longitude** of any place on the earth, is an arc of the equator contained between the meridian of that place and the meridian which is choſen for the firſt, where the reckoning of longitude begins.

Or, it is the angle at the pole formed by the firſt meridian, and that of the given place. The Engliſh compute the longitude of all places from the meridian of London.

XLVII. **Refraction**, in an Aſtronomical ſenſe, is the difference between the true and apparent altitudes of an object; it is owing to the atmoſphere's making all celeſtial objects appear more elevated above the horizon than they really are.

XLVIII. The **Twilight**, is that medium between light and darkneſs which happens in the morning before ſun-riſe, and in the evening after ſun-ſet. This is occaſioned by the atmoſphere's refracting the ſolar rays upon any place, although the ſun is below the horizon of that place; and by obſervation, it is found to begin and end at about 18° below the horizon.

XLIX. The **Crepusculem** is a ſmall circle parallel to the horizon at 18° below it.

That theſe Definitions and the following Problems may be the better underſtood, I ſhall ſhew the method of projecting the circles of the ſphere *in plaino.* There are three ſorts of projection, Stereographic, Orthographic, and Gnomonic; but the firſt being the beſt adapted to the preſent occaſion, I ſhall not inſiſt upon the latter two in this place, but refer to the word **Projection**, and Syſtem of **Dialling** for an account of the other.

In the Stereographic projection the eye is ſuppoſed to be placed at the pole of the plane, or primitive circle, on which the projection is made.

Problem I. *To project the Sphere upon the Plane of the Solſtitial Colure, or upon the Plane of the Meridian of any Place; thoſe Planes being ſuppoſed to coincide.*

The method: here the eye is ſuppoſed to be in the firſt point of ♈, or the common interſection of the equator, ecliptic and equinoctial colure; that being the pole of the plane of projection, or primitive circle.

1ſt. With a chord of 60 degrees deſcribe a circle PESQ, (Plate IV. *Figure* 1.) to repreſent the ſolſtitial colure, whoſe centre ♈ is its pole.

2d. A diameter EQ will be the equator, and another PS, at right angles to it will ſhew the equinoctial colure, or the axis of the world, whoſe extremities P, S, will be the North and South poles.

3d. For *Parallels of Declination.* On the primitive circle beginning at E and Q, lay off the chords of the given degrees of declination, ſuppoſe every 10 degrees; and alſo the diſtances of the tropics and polar circles from the equator, namely, 23°½ and 66½. Then from the centre ♈ in the axis PS, produced, apply the reſpective ſecants of the complements of the degrees laid on the primitive, and theſe will give the centres of the correſponding parallels of declination; from which centres with the extents to the ſeveral diviſions in the circumference, deſcribe the ſmall circles 10, 10; 20, 20; 30, 30; &c. and theſe will be the parallels of declination required. Among which *a*♋, *b*♑, are the tropics of Cancer and Capricorn; and *cc, dd,* the artic and antartic polar circles.

4th. *For the Circles of Right Aſcenſion*, or *Hour Circles.* In the diameter E Q produced, lay off from the centre ♈, both ways, the tangents of 15°, 30°, 45°, 60°, 75°, reſpectively; and they will be the centres of circles to be deſcribed through P, and S, cutting the equator in the points repreſenting the 24 hours; the ſolſtitial colure being the 12 o'clock, and the equinoctial colure, P. S. the 6 o'clock hour circles. And in like manner, may any other of theſe kind of circles be drawn.

5th. The *Ecliptic*, ♋ ♑ is drawn, making with the equator an angle of 23°½; whoſe poles *c, d,* are the interſections of the polar circles with the ſolſtitial colure.

6th. *Parallels of Celeſtial Latitude*, are drawn parallel to the ecliptic, in the ſame manner as circles of declination are drawn parallel to the equator.

7th. *Circles of Celeſtial Longitude* are deſcribed through *c, d,* the poles of the ecliptic, in the ſame manner as the circles of right aſcenſion were deſcribed through P, S, the poles of the equator; and thus were the diviſions found that are marked with the ſigns.

8th. The *Horizon* is repreſented by drawing a diameter HR making an angle with the axis PS, equal to the latitude of the place; and the poles of the horizon Z, N, the zenith and nadir are at 90° diſtant from the circle.

9th. *Azimuth*, or *Vertical Circles*, making any angle with the meridian, are deſcribed like circles of right aſcenſion. Thus ZN is the prime vertical, and ZAN is another azimuth, 45° from the ſouth.

10th. *Almicanthars*, or *Parallels of Altitude*, are in this projection drawn parallel to the horizon, in like manner as were the circles of declination drawn parallel to the equator.

Problem II. *To project the Sphere upon the Plane of the Horizon.*

In this projection the eye is ſuppoſed in one of the poles of the horizon, or plane of projection. (See Plate IV. *Figure* 2.)

1ſt. *The Horizon* is repreſented by the primitive circle, where the upper XII is the South; the lower XII, the North; E, the Eaſt; and Q, the Weſt points.

2d. *The Azimuth Circles*, are repreſented by diameters, drawn through Z, the centre or pole of the horizon. Thus the diameter XII, XII, is for the meridian, and EZQ for the prime vertical; and other azimuth circles, forming any angle with the meridian, are readily drawn by laying off their diſtances in the primitive, from the North or South points.

3d. *Parallels of Altitude*, are concentric to the primitive, and are deſcribed about the pole, Z, with the half tangent of their diſtance from it. Thus the ſmall circle, whoſe diameter is *ab*, is a parallel of altitude 10° above the horizon, or at 80° diſtance from its pole, Z.

4th. *The Equinoctial*'s diſtance from the zenith is equal to the latitude of the place, and therefore this circle makes with the horizon an angle, which is meaſured by the complement of the latitude; then, ſetting off from the centre Z, in Z XII, continued, the tangent of 50° (the latitude, in this Example, being ſuppoſed to be 40°) it will give the centre of the circle EAQ repreſenting the equinoctial; and the half tangent of 50°, ſet the ſame way from Z, will give P the pole of the world.

5th. *The Six o'Clock Hour Circle* paſſes through the poles of the world, making with the horizon an angle equal to the meaſure of the latitude; therefore, taking in the meridian from Z towards A, the tangent of the latitude 40°, it gives G, the centre of the ſix o'clock hour circle EPQ.

6th. *The Hour Circles* paſs through the poles of the world, and make with one another angles of 15°. Therefore, in a line DE, drawn through G, at right angles to the meridian, ſet off on both ſides of G, the tangents, 15°, 30°, 45°, 60°, 75°, to the radius PG, and they will give the centres of the ſeveral hour circles paſſing through P, and cutting the horizon and equinoctial in the hour points.

7th. *The Polar Circles, Tropics, and other Circles of Declination*, are deſcribed parallel to the equinoctial, about its pole P, at given diſtances from it, ſetting off on each ſide of Z, the half tangents of their greateſt and leaſt diſtances from Z; then the middles of thoſe intervals are the centres ſought.

Thus, the artic circle is diſtant from P about 23½°; then, to and from ZP = 50°, add and take 23½°, and there will be 73½° and 26½° reſpectively; and the half tangents of theſe ſet off from Z, give *p* and *q*; then, a circle being deſcribed on the diameter, *pq* is the artic circle.

In like manner will the centres of the tropic of Cancer *c*♋*c*, and of Capricorn *d*♑*d* be obtained.

8th. The northern portion of the ecliptic ♈♋♎ is deſcribed from a centre diſtant from Z towards P the tangent of 73½°, = the angle which the ecliptic makes with the horizon.

9th. *Circles of Longitude*, ♈*p*♎, *p*♉, *p*♊, *p*♌, *p*♍, are deſcribed through *p*, the pole of the ecliptic from centres in the line BFC, in like manner as the hour circles were deſcribed through P, the pole of the equator.

10th. *Circles of Celeſtial Latitude* VIII *q* VI, are deſcribed about *p* as the circles of declination were deſcribed about P, the pole of the equinoctial.

Problem III. *To project the Sphere upon the Plane of the Equator.*

In this projection the eye is ſuppoſed to be in one of the poles of the equator, (ſuppoſe in the ſouth pole) and projecting the north hemiſphere. (Plate IV. *Figure* 3.)

1ſt. *The Equator* is repreſented by the primitive circle, whoſe centre and pole is P.

2d. *The Hour Circles* are expreſſed by diameters making angles of 15° deg. with one another, of which XII P XII is the meridian or ſolſtitial colure, and VI P VI, the ſix o'clock circle, or equinoctial colure.

3d. *Circles of Declination*, are circles parallel and concentric to the equator, deſcribed from its centre with radii equal to the half tangents of their ſeveral diſtances from the pole P, or half co-tangents of their degrees of declination. Thus *pq*, the artic circle, and *a*♋; the tropic of Cancer are deſcribed with the half tangents of 23½°, and 66½° reſpectively, and ſo of the others.

4th. *The Ecliptic*, makes an angle of 23½° with the equator; therefore, the tangent of theſe degrees, laid from P towards *a*, will give the centre for deſcribing the ecliptic ♈♋♎, whoſe pole *p* is in the polar circle.

5th. *Circles of Longitude*, are deſcribed through *p*, the pole of the ecliptic, in like manner as the hour circles were deſcribed through P, the pole of the equator, in the laſt Problem; and thus were the diviſions ♉, ♊, ♌, ♍, obtained.

6th. *Circles of Celeſtial Latitude*, are projected in the ſame manner as the circles of declination in the laſt Problem.

7th. *The Horizon of any Place*, ſuppoſe of London, being inclined to the equator, in an angle equal to the co-latitude 38° 28′, the tangent of this, laid from P to Z, will give the centre, and Z the pole of the horizon HOR.

8th. *The prime Vertical* HZR, making an angle with the equator equal to the latitude of the place, 51° 32′, its centre is found by laying the tangent thereof from P towards *o*.

9th. *Azimuth Circles*, making given angles with the meridian, Z *o*, are thus deſcribed: In a line drawn through the centre of the prime vertical, at right angles to the meridian, take diſtances from that centre, equal to the tangents of the propoſed azimuth angles, the ſemidiameter of the prime vertical being radius, thoſe diſtances give the centres ſought; and thus was the azimuth, ZA, deſcribed.

10th. *Parallels of Altitude* are deſcribed about Z, the pole of the horizon, at the diſtances of the co-altitudes, in the ſame manner as were the circles of declination in the laſt Problem deſcribed about P, the pole of the equator; and thus was the ſmall circle V *b* VII deſcribed, at 10° diſtance from the horizon, or 80° diſtance from its pole Z.

PROBLEM IV. *To project the Sphere upon the Plane of the Ecliptic.*

The eye is here ſuppoſed to be in one of the poles of the ecliptic, and thence ſeeing the northern hemiſphere projected. Plate IV. *Figure* 4.

1ſt. *The Ecliptic* is here repreſented by the primitive circle, whoſe centre *p* is the pole of the ecliptic.

2d. *Circles of Longitude*, are herein ſhewn by diameters, thoſe making angles of 30° with one another being drawn through the diviſions marked with the ſigns of the zodiac.

3d. *Parallels of Celeſtial Latitude*, are circles deſcribed about *p*, concentric to the ecliptic; ſuch is the ſmall circle whoſe diameter is *ab*, repreſenting the parallel of 10° of latitude.

4th. *The Equator* makes an angle of 23½° with the ecliptic: therefore, the tangent of this inclination laid from *p* towards ♋, will give the centre of the equator ♈ XII ♎; and the half tangent of 23½° laid from *p*, the ſame way, gives P the pole of the equator.

5th. *The Equinoctial Colure*, which here makes the ſix o'clock hour circle, forms an angle with the ecliptic of 66½°, and the tangent thereof laid from *p* towards ♑, gives the centre of the ſix o'clock hour circle, ♈ P ♎.

6th. *Hour Circles*, paſſing through P, and making angles of 15° with one another, are deſcribed from centres, found in a right line paſſing through the centre of ♈ P ♎, and drawn at right angles to the ſolſtitial colure ♋ *p* ♑; by laying off in that line the tangents of 15°, 30°, 45°, 60°, 75°, reckoned from the centre of ♈ P ♎, on both ſides, the ſemidiameter of this circle being radius. Theſe hour circles cut the equator in the hour points.

7th. *Parallels of Declination*, ſuch as the tropic of Cancer, and artic circle, whoſe diameters are 12, 12, and *p q*, are deſcribed by laying off from *p*, the half tangents of their greateſt and leaſt diſtances. Thus *q*, being diſtant from *p* 47°, make *pq* = ½ tangent of 47°; then the middle of *pq* will be the centre of the polar circle.

8th. *The Horizon*, HOR, muſt make an angle with the ecliptic, equal to the difference between the co-altitude and the obliquity of the ecliptic, when P is projected to the north of *p*; otherwiſe, that angle is equal to the ſum of the ſaid quantities.

For London, where the aforementioned difference is 15° (= 38° 28′ — 23° 28′) the tangent of 15° gives the centre of HOR; and the half tangent gives Z the zenith.

9th. The prime vertical HZR, is deſcribed by laying from *p*, towards O, the co-tangent of *p*Z, for a centre.

10th. *Azimuth Circles* are deſcribed through Z, making given angles with the meridian ZO, by finding their centres in a line drawn through the centre of HZR in the manner deſcribed for the hour circles in Problem II.

11th. *Parallels of Altitude*, are repreſented by deſcribing ſmall circles parallel to the horizon HOR, at given diſtances from it; or, which comes to the ſame, by deſcribing ſmall circles about the pole Z, at diſtances equal to the complements of the given altitudes. And thus the circle *cdc* was deſcribed for a parallel of 33° of altitude.

PROBLEMS OF THE SPHERE.

PROBLEM V. *Given the Sun's Longitude, and the Obliquity of the Ecliptic; required the Sun's Right Aſcenſion and Declination.*

EXAMPLE. Let the obliquity of the ecliptic, or the ſun's greateſt declination, be 23° 28′; and let his place be 13° 16′ in ♉, what is his right aſcenſion and declination? (Plate IV. *Figure* 5.)

Here the primitive circle, PESQ, repreſents the plane of the ſolſtitial colure, whoſe centre is ♈; the diameter EQ is the equator; and the diameter PS, is the equinoctial colure; E ♋ is the ſun's declination, (= 23° 28′) ♋ ♑ is the ecliptic; ☉ is the place of the ſun; and ♈ ☉, is the ſun's longitude from ♈, = 43° 16′; alſo, P ☉ S is a circle of right aſcenſion.

Then in the right-angled ſpherical triangle ♈ ☉ B, there is given ♈ ☉ = 43° 16′, and the angle ☉ ♈ B = 23° 28′, to find ♈ B, the ſun's right aſcenſion, and B ☉, his preſent declination. Hence theſe proportions. See SPHERICAL TRIGONOMETRY.

As radius —	10.0000000	As radius —	10.0000000
Is to ſine ſun's long. ♈☉ (43° 16′)	9.8359408	To tangent ♈ ☉ (43° 16′)	9.9737071
So is S ∠ ☉ ♈ B (23° 28)	9.6001181	So coſ. ∠ ☉ ♈ B, (23° 28′)	9.9625076
To S B☉, the declination 15° 51′, *fere*	9.4360589	To tang. right aſcen. = 40° 48′ nearly	9.9362147

SCHOLIUM I. While the ſun is moving from ♈ to ♋, or is in the firſt quadrant of the ecliptic, the given longitude is the hypothenuſe in the triangle ♈ ☉ B, the declination B ☉ is north, and ♈ B is the right aſcenſion: but when the ſun has paſt the ſolſtice ♋, and is deſcending towards ♎, he is then ſaid to be in the ſecond quadrant, and his longitude or diſtance from ♈, being taken from 180°, the remainder ♎ ☉ becomes the hypothenuſe, and the declination is ſtill north; but the arc B ♎, which in the above caſe is the right aſcenſion, will then be only the ſupplement, and therefore it muſt be ſubtracted from 180°, in order to give the right aſcenſion required.

SCHOLIUM II. When the ſun is paſt the point ♎, and deſcending towards ♑, has got into the third quadrant, then the longitude reckoned from ♈ will be greater than 180°.

In this caſe, the exceſs above 180°, or the diſtance the ſun is removed from ♎, will be the hypothenuſe ♎ ☉; the declination will be South, and the arc ♎ A, found for the right aſcenſion muſt be added to 180°, to give the right aſcenſion eſtimated from ♈.

SCHOLIUM III. When the ſun has paſt the ſolſtice ♑, and is deſcending towards ♈, he is then in the fourth quadrant, and therefore its longitude is greater than 270°, and muſt be taken from 360°, to give the hypothenuſe ♎ ☉.

In this caſe the declination is South, and the right aſcenſion ♎ A, as found by the proportion, muſt be taken from 360° to give the right aſcenſion from ♈.

COR. At equal diſtances from the equinoctial points ♈ or ♎, the ſun will have equal quantities of declination, but they will be of different names, according as the ſun is on the north or ſouth ſides of the equinoctial.

PROBLEM VI. *Given the Obliquity of the Ecliptic, and the Sun's preſent Declination, to find his Longitude and Right Aſcenſion.*

Here, in the ſaid right-angled ſpherical triangle ♈ ☉ B, there are given the angle ☉ ♈ B, or ſun's greateſt declination, (23° 28′) and ☉ B, the preſent declination, to find ♈ ☉. the ſun's longitude; and ♈ B, his right aſcenſion.

And therefore, by Trigonometry, As ſine ∠ ☉ ♈ B (the greateſt declination) : ſine ☉ B (the preſent declination) : : radius : ſine ♈ ☉, the ſun's longitude; and as radius : co-tangent ∠ ☉ ♈ B : : tangent ☉ B : ſine of the right aſcenſion.

N. B. The right aſcenſion may be either greater or leſs than a quadrant. But when the ſun's longitude is greater than a quadrant, his right aſcenſion will be ſo too.

It would be ſuperfluous to enumerate examples. If the deſcription of each Problem, and the proportions for the ſolution thereof be laid down, nothing farther can be either neceſſary or deſirable in a work of this kind. For the reſt lays merely in taking out and adding up, &c. the logarithms for each caſe, which none who are acquainted with the previous requiſites (namely TRIGONOMETRY) can be ignorant of.

PROBLEM VII. *Given the Obliquity of the Ecliptic, and the Sun's Right Aſcenſion, to find his Longitude and preſent Declination.*

Here, in the aforeſaid right-angled ſpheric triangle, ♈ ☉ B, the leg ♈ B, or given right aſcenſion, and ∠ ☉ ♈ B, or obliquity of the ecliptic, being known, the hypothenuſe ♈ ☉, or ſun's longitude, and the other leg, ☉ B, or his preſent declination, will be found by the following proportions:

1ſt. As rad. : co-tangent ∠ ☉ ♈ B : : co-tangent ♈ B : co-tangent ♈ ☉.

2d. As rad. : tangent ∠ ☉ ♈ B : : ſine ♈ B : tangent ☉ B.

PROBLEM VIII. *Given the Latitude of the Place, and the Sun's preſent Declination; required the Sun's Altitude and Azimuth at 6 o'Clock?*

Here, in Plate IV. *Figure* 6. HR is the horizon; ZN, the prime vertical; RP, the latitude; PS, the ſix o'clock hour circle; EQ, the equator; *n m*, the parallel of declination; and ZON, the azimuth circle.

Now the things given and required, fall in either of the right angled triangles Z☉P, or ♈☉A, they being ſupplemental triangles to each other. In the former ſpheric triangle, right angled at P, there are given ZP, the co-latitude; ☉P, the complement of the declination to find Z☉, the co-altitude, and the ∠ ☉ZP = the azimuth; or, in the ſpheric triangle ♈A☉, right angled at A, there are given the latitude A♈☉, and the declination ♈☉, to find A☉, the altitude, and ♈ A the co-azimuth; in which caſe the proportions are as follow:

MUSEUM

As rad. : ſine ♈☉ : : ſine A♈☉ : ſine A☉ the altitude. And as rad. : coſine A♈☉ : : tangent ♈☉ : tangent ♈A, the co-azimuth, which taken from 90° leaves the azimuth required.

Scholium. From a due conſideration of this Problem, it is evident, that as the declination increaſes, the altitude increaſes, but the azimuth leſſens; and the contrary happens, while the declination is diminiſhing. Hence, when the ſun has no declination, the altitude at ſix o'clock will be nothing, or the ſun will be in the horizon; and the azimuth then being 90°, the ſun will riſe due eaſt in the morning, and ſet due weſt in the evening.

Problem IX. *Given the Latitude of the Place, and the Sun's Declination. Required tho Altitude and Hour, when the Sun is due Eaſt and Weſt?* See Plate IV. *Figure* 7.

The primitive circle is the meridian; HR, the horizon; ZN, the prime verticle; RP, the latitude; PS, the ſix o'clock hour circle; EQ, the equator; *nm*, the parallel of declination; ☉ the ſun's place, and P☉S, the hour circle. Here the things concerned in the Problem, fall in either of the triangles PZ☉, or ♈A☉.

In the ſpheric triangle PZ☉, right angled at Z, there are given PZ, the co-latitude, and P☉ the co-declination, to find Z☉ the co-altitude, and ∠ZP☉, the hour from noon.

Alſo in the ſpheric triangle ♈A☉, right angled at A, there are given ∠A♈☉ = latitude, and A☉ = declination; to find ♈☉, the altitude, and ♈A, the hour from ſix o'clock; for which the proportions are as under.

As ſine ∠A♈☉ : ſine A☉ : : rad. : ſine ♈☉, the altitude. And as rad. : co-tangent A♈☉ : : tangent A☉ : ſine A♈, the aſcentional difference or time from 6, which muſt be turned into hours and minutes, &c. by reckoning 15° to the hour; and then this added to ſix o'clock, gives the time in the morning when the ſun is eaſt; or ſubtracted therefrom, leaves the time in the evening when the ſun is weſt.

Scholium. When the latitude of the place and ſun's declination have the ſame name, then the greater the declination and latitude, the greater will be the altitude and time from 6. Likewiſe, when they have contrary names, the ſame things happen; but with this difference, that in the former caſe the days lengthen on account of the increaſe of the latitude and declination; whereas, in the latter caſe, the days ſhorten on that account.

Problem X. *Given the Latitude of a Place, and the Sun's Declination. Required his Amplitude and Aſcenſional Difference.* See Plate IV. *Figure* 8.

Here the primitive circle is the meridian of the place; HR, is the horizon; RP, the latitude; PS, the 6 o'clock hour circle; EQ, the equator; *nm*, the parallel of declination; ☉, the place of the ſun; and P☉S, the hour circle.

Then as the arc QR = co-latitude, meaſures the ∠Q♈R, there are given in the ſpheric triangle ♈☉A, (right angled at A) the ſun's declination = A☉; the co-latitude, A♈☉, to find the amplitude ♈☉ and the aſcenſional difference ♈A. Wherefore as ſine ∠A♈☉ : ſine A☉ : : rad. : ſine ♈☉, the amplitude, reckoned from the eaſt or weſt points of the horizon.

And as rad. : tangent ∠A♈O : : tangent of AO : ſine ♈A, the aſcenſional difference.

Scholium I. If the declination is north, the amplitude is north; and if ſouth, it is ſouth.

Scholium II. If *rs* be a parallel of declination, as far ſouth as *mn* is north; the hour circle PBS. paſſing through ☉, the place of the ſun at his riſing or ſetting will form a triangle ♈☉B = △♈☉A, where the amplitude is to the ſouthward of the eaſt and weſt points.

Scholium III. When the latitude and declination have the ſame name, the ſun riſes before and ſets after 6, and then the aſcenſional difference converted into time muſt be ſubtracted from 6 for the time of ſun-riſe, and added to 6 for the time of the ſun's ſetting; but when they are of contrary names, the ſun riſes after and ſets before 6, in which caſe the aſcenſional difference in time muſt be added to 6, for the time of riſing, and ſubtracted therefrom for the time of ſetting.

Scholium IV. The time of the ſun's ſetting being doubled, gives the length of the day; and the double of the time of his riſing, gives the length of the night.

Scholium V. When the latitude and declination have the ſame name, the difference between the right aſcenſion and the aſcenſional difference, is the oblique aſcenſion; and their ſum is the oblique deſcenſion: but when they are of contrary names, their ſum is the oblique aſcenſion, and their difference is the oblique deſcenſion.

Scholium VI. When the declination is equal to the co-latitude of any place (which can only happen to the places within the polar circles) then the parallel of the declination will not cut the horizon, and conſequently the ſun will not ſet in thoſe places during the time his declination exceeds the co-latitude. The like alſo holds with reſpect to the ſtars, for every ſtar whoſe co-declination, or polar diſtance, is not leſs than the latitude; or which is the ſame thing, whoſe declination is not leſs than the co-latitude of the place, thoſe ſtars will never deſcend below the horizon of that place: however, the above is to be only underſtood, when they are in the ſame hemiſphere with the given place; for when the ſtars are in a contrary hemiſphere, and the co-latitude of the place does not exceed the declination of thoſe celeſtial objects, then will they never riſe above the horizon of that place, and conſequently are never viſible there.

Problem XI. *Given the Latitude of a Place, the Sun's Declination and Altitude. Required the Hour from Noon and the Azimuth?* See Plate IV. *Figure* 9.

The primitive circle ZRNH, repreſents the meridian of the place; HR, the horizon; ZN, the prime vertical; RP, the latitude of the place; EQ, the equator; *nm*, the parallel of declination; *rs*, the parallel of altitude; ☉, the place of the ſun; Z☉N, an azimuth circle; and P☉S, an hour circle.

Then in the oblique angled ſpherical triangle P☉Z there are given the co-latitude, ZP; the co-altitude, or Zenith diſtance, Z☉; and the co-declination, or polar diſtance, ☉P; to find ∠☉ZP = the azimuth, and ∠☉PZ = the hour from noon. Hence by trigonometry.

As ſine Z☉ × ſine ZP : rad. : : ſine $\frac{\odot P+ZP-Z\odot}{2}$ × ſine $\frac{\odot P+Z\odot-ZP}{2}$: ſine ſquare of ½ ∠☉ZP, the degrees of which being doubled gives the ∠☉ZP, the azimuth.

And as ſine PZ × ſine ☉P : rad. ſquare : : ſine $\frac{Z\odot+ZP-\odot P}{2}$ × ſine $\frac{Z\odot+\odot P-ZP}{2}$: ſine ſquare of ½ ∠☉PZ; then the degrees, &c. of this being doubled gives ∠☉PZ, which, when converted into time, is the time from noon required.

N. B. Theſe proportions are adapted to the uſe of natural ſines, &c. but will be equally inſtructive in the caſe of *logarithm ſines*, to thoſe who are ſufficiently acquainted with their nature and uſe.

Problem XII. *Given the Latitude of the Place, and Sun's Declination. Required the Time when the Twilight begins and ends?* See Plate IV. *Figure* 10.

Here ZRNH is the meridian of the place, HR, the horizon ZN, the prime vertical, and *ts* a ſmall parallel circle at 18° below it; alſo RP is the latitude; EQ, the equator; *nm*, the parallel of declination; ☉, the place of the ſun; Z☉N, a vertical circle; and P☉S, the hour circle.

Then in the oblique angled ſpheric triangle Z☉P, there are given the co-latitude ZP, and the polar diſtance or co-declination, P☉; to find ∠ZP☉, the hour from noon.

This caſe is ſimilar to the latter in the preceding Problem; I ſhall therefore not repeat the proportion, but give a rule for ſolving the ſame by logarithms.

Take the ſine log. co-arith. P☉, the ſine log. co-arith. ZP, the log. ſine $\frac{Z\odot+P\odot-PZ}{2}$, and the log. ſine $\frac{Z\odot-P\odot+PZ}{2}$, add the whole together, then the half ſum will be equal to the ſine of ½ ∠ZP☉, the degrees, &c. of which being doubled, give ZP☉, which being converted into hours, &c. is the time from from noon. Wherefore, ſubtracting the ſame from 12, will give the time of day break, and adding it to 12, will ſhew the end of twilight.

N. B. When the declination becomes greater than the difference between the co-altitude and 18°, then the parallel of declination *nm*, will not cut the parallel *ts* 18° below the horizon; and conſequently at that time there will be no night in that place, but the twilight will continue from ſun ſetting to ſun riſing.

Problem XIII. *Given the Time of the Year, the Latitude of the Place, and the Altitude of a known fixed Star. Required the Hour of Night, when the Obſervation was made?* See *Figure* 11.

Here the meridian, horizon, and equator, are as before; *rs*, the parallel of altitude; ZP, is the co-latitude of the place; *nm*, the parallel of the ſtars declination; ✳, the place of the ſtar; Z✳N, a vertical circle; and P✳S, the hour circle. Then in the oblique angled ſpheric triangle P✳Z, there are given PZ, the co-latitude; Z✳, the co-altitude; ✳P, the polar diſtance, or co-declination of the ſtar, to find ∠ZP✳, or the hour from noon.

This is alſo a ſimilar caſe to the latter in Problem XI. and the ſame proportion will hold, ſubſtituting the ſtar for the ſun.

N. B. The ſtar's declination muſt be taken from a correct table of known ſtars, adjuſted to the preſent time.

Problem XIV. *Given the Obliquity of the Ecliptic, and a Star's right Aſcenſion and Declination. Required his Latitude and Longitude?* See *Figure* 12.

Here the primitive circle repreſents the ſolſtitial colure, EQ the equator; *nm* the parallel of the ſtars declination; ♈*a* is equal to the ſtars right aſcenſion P✳S, a circle of right aſcenſion; ✳ the place of the ſtar; E♋ = 23° : 28′, the obliquity of the ecliptic; ♋♑, the ecliptic; *p* and *q*, its poles; and *p*✳*q*, a circle of longitude.

Then in the oblique angled ſpheric triangle *p*P✳, there is given the obliquity of the ecliptic *p*P, the co-declination P✳, and the right aſcenſion = ∠pP✳, to find p✳, the co-latitude, and ∠Pp✳ = longitude.

Therefore by ſpheric trigonometry. As rad. : coſine of right aſcenſion :: tangent of the obliquity of the ecliptic : tangent of a 4th arc, which will be acute or obtuſe, according as ∠pP✳ is acute or obtuſe.

Alſo take the difference between this 4th arc, and the co-declination P✳; and call that the 5th arc. Then it will be as the coſine of the 4th arc : coſine of the 5th arc :: coſine of the obliquity of the ecliptic : the ſine of the required latitude, which will be north or ſouth, according as the ſtar by its declination is north or ſouth of the ecliptic.

Alſo as ſine of the co-latitude, thus found : ſine of the co-declination :: ſine of right aſcenſion to the coſine of the longitude, which will be in the ſame quadrant with the right aſcenſion.

N. B. On account of the preceſſion of the equinoxes, the fixed ſtars, although they keep always the ſame latitudes, are nevertheleſs conſtantly altering their longitudes, declinations, and right aſcenſions; the alteration in longitude is uniformly about 50″ yearly; but that of the right aſcenſion and declination is continually varying. So that many ſtars which once had north declination come to have ſouth, while others are changing from ſouth to north declination.

Problem XV. *Given the right Aſcenſions and Declinations of two fixed Stars. Required their Diſtance?* See Plate IV. *Figure* 13.

Let the primitive circle repreſent the circle of right aſcenſion of that ſtar, whoſe right aſcenſion is the greateſt; and let a circle of right aſcenſion PAS be drawn, ſo as to make an angle with PBS equal to the difference between the given right aſcenſions; then drawing the parallels of declination B*m* and *rs*, the interſections B and A will be the places of the two ſtars; B, being that whoſe right aſcenſion is the greateſt, and A, the other. Then drawing a great circle, BAC, through BA, there will be given in the ſpheric triangle BPA, the ſide BP = co-declination of the ſtar B; PA = co-declination of the ſtar A; and the included angle APB = difference of their right aſcenſions, to find their diſtance AB.

The data in this Problem is therefore the ſame as in the laſt, and the ſame method which ſolves the firſt caſe of that Problem, is equally applicable in this. See alſo Spherical Trigonometry.

Problem XVI. *Given the Latitudes and Longitudes of two known fixed Stars. Required their Diſtance?*

The conſtruction of this Problem, is like that of the laſt; only, inſtead of circles of right aſcenſion, read circles of longitude; and uſe parallels of latitude, inſtead of parallels of declination.

The method of computation is alſo the ſame, there being given two co-latitudes; and the included angle, which is the difference between the given longitudes.

Problem XVII. *Given the Latitude and Longitude of a fixed Star, and alſo the Obliquity of the Ecliptic. Required the Right Aſcenſion and Declination of ſuch Star?*

The conſtruction of this Problem is much the ſame as that of Problem XIV. only here the interſection of a parallel of latitude *cb*, with a circle of longitude *p*A*q*, will give the place of the ſtar.

The computation is alſo as in Problem XIV. for here are given P*p*, the obliquity of the ecliptic, *p*A = co-latitude, and ∠P*p*A = co-longitude, to find PA the co-declination, and ∠*p*PA, the right aſcenſion.

Problem XVIII. *Given the Meridional Altitude of any Celeſtial Object, ſuppoſe a Comet, its Diſtance from a known Star, and the Latitude of the Place. Required the Declination and right Aſcenſion of that Comet.* See *Figure* 14.

The primitive circle repreſents the meridian of the place; HR, the horizon; and ZN, the prime vertical; alſo RP = the latitude; EQ the equator; *nm* the parallel of declination of the propoſed ſtar; HO, the altitude of the comet; *aa*, a ſmall circle; O*a* being equal to the diſtance of the comet from the ſtar; and the place (✳) where it interſects *nm*, is the poſition of the ſtar at that time; likewiſe P✳S is a circle of right aſcenſion; and ⊙✳, a part of a great circle.

Then ſince HE is equal to the co-latitude, and HO = the altitude of the comet, it follows that EO, the required declination = HO∽HE, which is north, when the altitude exceeds the co-latitude.

Alſo, in the triangle P✳O, there are given the three ſides, viz. PO = co-declination of the comet; ⊙✳ = diſtance between the comet and ſtar, and P✳ the co-altitude; to find the ∠OP✳, the difference between the right aſcenſions of the comet and ſtar; for the ſolving of which ſee Spherical Trigonometry; then this difference ſubtracted from or added to the ſtar's right aſcenſion, according as the ſame is greater or leſs than the comets, will give the right aſcenſion of the comet.

Problem XIX. *Given the Latitude of a Place, the Sun's Declination and Azimuth, required his Altitude, and the Time of Obſervation.* See Plate IV. *Figure* 15.

To illuſtrate this by an Example:

Let the latitude be 13½° north, and the ſun's declination 23° 28′ north; required the ſun's altitude, and the time of the day when he is ſeen on the ENE azimuth circle.

Here the primitive circle repreſents the meridian of the place, HR, the horizon; ZN, the prime vertical; RP = the latitude; PS, the ſix o'clock hour circle; EQ, the equator; *nm*, the parallel of the ſun's greateſt declination; ZDN, the vertical circle, which cuts the parallel *nm* in the points A and B, and thereby ſhews, that at two diſtant times in the forenoon the ſun will have the azimuth propoſed; PAS and PBS, drawn through the points of interſection, A and B, are hour circles.

Now, in the ſpheric triangle PZA or PZB, there are known the co-latitude PZ = 76½°, the co-declination PA or PB = 66° 32′, and the azimuth angle, PZD = 67½°, to find ZA or ZB, and the ∠ZPA or ∠ZPB.

Now, as radius : coſ. azimuth :: co-tangent latitude : tangent of a fourth arc (M) = 57° 54′; and, as the ſine latitude : ſine declination :: coſ. M. : coſ. of a fifth arc (N) = 24° 54′.

Then, M + N, or 57° 54′ + 24° 54′ = 82° 48′ = ZA, the complement of the leſs altitude; and M − N, or 57° 54′ − 24° 54′ = 33° = ZB, the complement of the greater altitude. Therefore, when the ſun has 7° 12′, or 57° of altitude, he is on the given azimuth.

Again: As coſ. declination : ſine of azimuth :: coſ. leſs altitude : ſine of hour from noon = 88° 2′; and :: coſ. greater altitude : ſine of hour from noon = 33° 16′.

Alſo, 88° 2′ = in time, 5 hours, 52 minutes; and 33° 16′ = 2 hours, 13 minutes, the reſpective times from noon; and conſequently the ſun will be ſeen on the ENE azimuth, at 6 hours, 8 minutes, and again at 9 hours, 48 minutes in the morning. In the afternoon he will be ſeen on the WNW azimuth at 2 hours, 13 min. and at 5 hours, 52 minutes.

If it is required to find at what altitude the greateſt azimuth will happen at that place on the ſame day; then, ſince the azimuth circle in that caſe muſt touch the parallel *nm*, the greateſt diſtance of the equator will be 23° 28′; and, as their poles muſt be at the ſame diſtance, the interſection *p* of a ſmall circle (*rs*) with the horizon deſcribed about the pole S, at the diſtance of 23° 28′, will be the pole of the circle ZCN; then, having deſcribed an hour circle, PCS through *p*, there will be given in the ſpheric triangle, ZPC right-angled at C, the co-latitude PZ = 76½°, and the co-declination PC = 66° 32′, to find the greateſt azimuth or ∠; PZC, (= 70° 36′) the diſtance, ZC, (= 54° 8′); and the hour from noon (= 56° 27′) = 3 hours, 46 minutes.

Problem XX. *Given the Sun's Declination and Amplitude to find the Latitude of the Place.*

Here (Plate IV. *Fig.* 16) HR is the horizon; RO, the azimuth; EQ, the equator; ♈O, the co-amplitude; AO, the declination; and ∠A♈O, the co-latitude; therefore, in the ſpheric triangle, ♈OA, right-angled at A, there is given ♈O and AO to find ∠A♈O. The proportion is, as ſine ♈O : radius :: ſine AO : ſine ∠A♈O, the co-latitude required.

Problem XXI. *Given the Sun's Declination and his Aſcenſional Difference; required the Latitude of the Place.*

If the foregoing Problems, with their conſtructions, are well underſtood, the reader will not be at a loſs in deſcribing this and the remaining Problems in this Section; and therefore I ſhall only give the method of calculation in each caſe, and paſs over the conſtructions, that we may find room for other matters that are more eſſential to Aſtronomy. The proportion in this caſe is, as radius : co-tangent of the declination :: ſine of the aſcenſional difference : tangent of the latitude.

Problem XXII. *Given the Sun's Declination and Altitude at ſix o'Clock; required the Latitude of the Place.*

Solution.

As ſine of the declination : radius :: ſine of altitude : ſine of latitude.

Problem XXIII. *Given the Sun's Declination and Altitude when he is due Eaſt or Weſt; required the Latitude of the Place.*

Solution.

As ſine of altitude : radius :: ſine of declination : ſine of the latitude.

Problem XXIV. *Given the Sun's Altitude and Hour of the Day, on either Equinox; required the Latitude of the Place.*

Solution.

As ſine of the time from ſix : radius :: ſine altitude : coſine of latitude.

Problem XXV. *Given the Sun's Altitude, Declination and Azimuth; required the Latitude of the Place.*

Solution.

As radius : coſine azimuth :: co-tangent altitude : tangent of a fourth arc. And, as ſine of altitude : ſine declination :: coſine of fourth arc : coſine of a fifth arc. Then the difference between the fifth and fourth arcs is the co-latitude.

Problem XXVI. *Given the Sun's Declination, his Altitude, and the Hour of the Day; required the Latitude of the Place.*

Solution.

As radius : coſine of hour from noon :: co-tangent of declination : tangent of a fourth arc. And, as ſine declination : ſine altitude :: coſine of fourth arc : coſine of fifth arc, Then the difference between thoſe arcs is the co-latitude.

Other Problems might be added, but they are ſuch as ſeldom occur in practice; and thoſe who perfectly underſtand how to ſolve what have been here given, will not find it difficult to ſolve any other of the like nature, the whole depending on the doctrine of ſpherical triangles.

But ſeveral of the foregoing Problems may alſo be applied to other caſes than thoſe propoſed; viz. when the things concerned in each are the ſame, but with this difference, that the thing required in one caſe be given in the other, and that one of the things given in one caſe, be required in the other; for then the ſolution is had by merely varying the proportion.

Thus, in Problem XXIV. ſuppoſe the latitude had been given and the altitude required, then the proportion would have been as radius : ſine of hour from ſix : : coſine latitude : ſine of altitude; and ſo for any other; obſerving, that when the firſt term of any of the proportions is wanted, it will be, as 4th term : 3d term : : 2d term : 1ſt term. When the 2d term is wanted, it will be, as the 3d term : 4th term : : 1ſt term : term required; and when the 3d term is ſought, it will be, as the 2d term : 1ſt term : : 4th term : 3d term; it being evident, from the nature of equations and the doctrine of Ratio's, that the proportions will hold in each caſe.

SECT X.

OF THE TIDES:

Or, an Explanation of the Flux and Reflux of the Sea.

TO account for the ebbing and flowing of the ſea, is a ſubject that has excited the attention of philoſophers in every age; but the diſcovery of its true cauſe was reſerved for the honour of the illuſtrious Newton, who has ſhewn that the flux and reflux of the ſea is a natural conſequence reſulting from the laws and principles of gravitation, effected by the action of the moon upon the earth, or rather by the joint actions of the ſun and moon; that, however, of the moon, being by far the moſt conſiderable.

In explaining the phænomena of the tides it muſt be obſerved, that the power of gravity diminiſhes as the ſquare of the diſtance increaſes; and therefore the waters at Z (See Plate IV. *Figure* 17.) on the ſide of the earth ABCDEFGH next the moon M are more attracted than the central parts of the earth O by the moon, and the central parts are more attracted by her than the waters on the oppoſite ſide of the earth at *n*; and therefore the diſtance between the earth's centre and the waters on its ſurface under and oppoſite to the moon will be increaſed. For, let there be three bodies at H, O, and D; if they are all equally attracted by the body M, they will all move equally faſt toward it, their mutual diſtances from each other continuing the ſame. If the attraction of M is unequal, then that body which is moſt ſtrongly attracted will move faſteſt, and this will increaſe its diſtance from the other body. Therefore, by the law of gravitation, M will attract H more ſtrongly than it does O, by which the diſtance between H and O will be increaſed; and a ſpectator on O will perceive H riſing higher toward Z. In like manner, O being more ſtrongly attracted than D, it will move farther towards M than D does: conſequently, the diſtance between O and D will be increaſed; and a ſpectator on O, not perceiving his own motion, will ſee D receding farther from him towards *n*; all effects and appearances being the ſame, whether D recedes from O, or O from D.

Suppoſe now there is a number of bodies, as A,B,C,D,E,F,G,H, placed round O, ſo as to form a flexible or fluid ring: then, as the whole is attracted towards M, the parts at H and D will have their diſtance from O increaſed; whilſt the parts at B and F being nearly at the ſame diſtance from M as O is, theſe parts will not recede from one another; but rather, by the oblique attraction of M, they will approach nearer to O. Hence, the fluid ring will form itſelf into an ellipſe ZIBL*n*KFNZ, whoſe longer axis *n*OZ produced, will paſs through M, and its ſhorter axis BOF will terminate in B and F. Let the ring be filled with fluid particles, ſo as to form a ſphere round O; then, as the whole moves towards M, the fluid ſphere being lengthened at Z and *n*, will aſſume an oblong or oval form. If M is the moon, O the earth's centre, ABCDEFGH the ſea, covering the earth's ſurface, it is evident, by the above reaſoning, that whilſt the earth by its gravity falls toward the moon, the water directly below her at B will ſwell and riſe gradually towards her; alſo the water at D will recede from the centre (ſtrictly ſpeaking, the centre recedes from D), and riſe on the oppoſite ſide of the earth; whilſt the water at B and F is depreſſed, and falls below the former level. Hence, as the earth turns round its axis from the moon to the moon again in 24⅘ hours, there will be two tides of flood and two of ebb in that time, as we find by experience.

As this explanation of the ebbing and flowing of the ſea is deduced from the earth's conſtantly falling towards the moon by the power of gravity, ſome may find a difficulty in conceiving how this is poſſible, when the moon is full, or in oppoſition to the ſun; ſince the earth revolves about the ſun, and muſt continually fall towards it, and therefore cannot fall contrary ways at the ſame time: or if the earth is conſtantly falling towards the moon, they muſt come together at laſt. To remove this difficulty, let it be conſidered, that it is not the centre of the earth that deſcribes the annual orbit round the ſun, but the common centre of gravity of the earth and moon together: and that whilſt the earth is moving round the ſun, it alſo deſcribes a circle round that centre of gravity; going as many times round it in one revolution about the ſun as there are lunations or courſes of the moon round the earth in a year: and therefore the earth is conſtantly falling towards the moon from a tangent to the circle it deſcribes round the ſaid common centre of gravity.

The earth's diameter bears a conſiderable proportion to its diſtance from the moon; but is next to nothing when compared to its diſtance from the ſun. Therefore the difference of the ſun's attraction on the ſides of the earth under and oppoſite to him, is much leſs than the difference of the moon's attraction on the ſides of the earth under and oppoſite to her; and conſequently the moon muſt raiſe the tides much higher than they can be raiſed by the ſun.

From this theory it may be thought the tides ought to be higheſt directly under and oppoſite to the moon. But we find, that in open ſeas, where the water flows freely, the moon is generally paſt the meridian, when it is high water. The reaſon is obvious: for though the moon's attraction was to ceaſe altogether, when ſhe was paſt the meridian, yet the motion of aſcent communicated to the water before that time, would make it continue to riſe for ſome time after; much more muſt it do ſo when the attraction is only ſomething diminiſhed.

Thus, to inſtance a ſimilar caſe, experience ſhews, that the day is hotter about three in the afternoon, than when the ſun is on the meridian, becauſe of the increaſe made to the heat already imparted.

The tides anſwer not always to the ſame diſtance of the moon from the meridian at the ſame places; but are variouſly affected by the action of the ſun, which brings them on ſooner when the moon is in her firſt and third quarters, and keeps them back later when ſhe is in her ſecond and fourth: becauſe, in the former caſe, the tide raiſed by the ſun alone would be earlier than the tide raiſed by the moon; and, in the latter caſe, later.

When the moon is neareſt the earth, ſhe attracts ſtrongeſt, and ſo raiſes the tides moſt; the contrary happens when ſhe is fartheſt from the earth, becauſe of her weaker attraction. When both luminaries are in the equator, and the moon in perigee, ſhe raiſes the tides higheſt of all, eſpecially at her conjunction and oppoſition; both becauſe the equatorial parts have the greateſt centrifugal force from their deſcribing the largeſt circle, and from the concurring actions of the ſun and moon. At the change, the attractive forces of the ſun and moon being united, they diminiſh the gravity of the waters under the moon, and their gravity on the oppoſite ſide is diminiſhed by means of a greater centrifugal force. At the full, whilſt the moon raiſes the tide under and oppoſite to her, the ſun, acting in the ſame line, raiſes the tide under and oppoſite to him; whence their conjoint effect is the ſame as at the change; and, in both caſes, occaſion what we call the Spring Tides. But at the quarters the ſun's action on the waters at O and H diminiſhes the effect of the moon's action on the waters at Z and N; ſo that they riſe a little under and oppoſite to the ſun at O and H, and fall as much under and oppoſite to the moon at Z and N; making what we call the Neap Tides, becauſe the ſun and moon then act croſs-wiſe to each other. But theſe tides happen not till ſome time after; becauſe in this, as in other caſes, the actions do not produce the greateſt effect when they are at the ſtrongeſt, but ſome time afterward.

The ſun, being nearer the earth in winter than in ſummer, therefore the greateſt tides happen not till ſome time after the autumnal equinox, and return a little before the vernal.

As the tides are principally governed by the moon, they muſt turn on the axis of the moon's orbit, or nearly ſo, which is inclined 23½ degrees to the earth's axis at a mean ſtate: and therefore the poles of the tides muſt be ſo many degrees from the poles of the earth, or in oppoſite points of the polar circles, going round theſe circles in every lunar day.

When the moon is in the equator, the tides are equally high in both parts of the lunar day, or time of the moon's revolving from the meridian to the meridian again, which is 24 hours 50 minutes. But as the moon declines from the equator towards either pole, the tides are alternately higher and lower at places having North or South latitude. Whilſt the moon has North declination, the greateſt tides in the northern hemiſphere are when ſhe is above the horizon; and the reverſe whilſt her declination is South.

But the tides are ſo retarded in their paſſage through different ſhoals and channels, and otherwiſe ſo variouſly affected by ſtriking againſt capes and headlands, that to different places they happen at all diſtances of the moon from the meridian, conſequently at all hours of the lunar day. The tide propagated by the moon in the German ocean, when ſhe is three hours paſt the meridian, takes 12 hours to come from thence to London bridge; where it arrives by the time that a new tide is raiſed in the ocean. And therefore, when the moon has North declination, and we ſhould expect the tide at London to be greateſt when the moon is above the horizon, we find it is leaſt; and the contrary, when ſhe has South declination. At ſeveral places it is high-water three hours before the moon comes to the meridian; but that tide which the moon puſhes as it were before her, is only the tide oppoſite to that which was raiſed by her when ſhe was nine hours paſt the oppoſite meridian.

SECT. XI.

Of the Aberration of the fixed Stars, cauſed by the Compound Motion of the Rays of Light, and of the Earth in its Orbit.

IT is found from obſervations of the eclipſes of Jupiter's ſatellites, that light is about 8 minutes in paſſing from the ſun to the earth: and as the earth deſcribes about 1° in a day, it will therefore in 8 minutes deſcribe 20″ in its orbit; and conſequently the velocity of light is to the velocity of the earth in its orbit, as radius to an arc of 20″, or as 10300 to 1.

Now, if AN (Plate IV. *Figure* 18.) be the path of a body in free ſpace, its apparent way on a moveable plane will be different, for it will be that which is made by the reſolution of the two motions on a moveable plane.

Thus let AN be deſcribed in any time by the body, and NF be deſcribed by (a point in) the plane, in the ſame time. Now as the plane moves forward in the direction NF or AB, it leaves all the points of the fixed line AN behind it; all of which will therefore ſeem to move backwards in the plane. Therefore make ND = NF, for the body, inſtead of going to N in free ſpace will ſeem to go to D, and therefore AD will be the apparent path of the body in that plane. Therefore a ray of light emitted from the ſtar in the direction AN, will fall upon the point D of the moving plane; and, hence, an obſerver at D will ſuppoſe the ſtar ſituated in the line DA. Conſequently, if BN be parallel to AD, and the point D tranſlated to N in the ſaid time, an obſerver at N will ſuppoſe the ſtar ſituated in the line NB, making the angle BNF or ADF leſs than ANF, the angle, which it would appear under if the plane was at reſt; ſo that the angle of elevation BNF above the line of direction NF of the obſerver, is leſs than before, being taken on the ſide towards which the obſerver moves. The ooſerver, therefore, inſtead of ſeeing the ſtar at A its real place will ſee it at B, its apparent place. On the contrary, if the obſerver moves from F to N and D; and B, be the real place of the ſtar; then to an obſerver if at N, its apparent place would be at A.

The apparent place B is always in the plane of aberration, drawn through the way of the obſerver NF, and the line NA drawn from the obſerver to the real place of the ſtar; for AB, being parallel to NF, is in the plane ADNF, and the angle BNA or NAD, is the angle of aberration; and by the quantity of this angle, the ſtar is depreſſed, in going towards it; or raiſed in going from it.

Now in the triangle AND it is as AN : ND :: ſine ADN : ſine NAD; but AN and ND being given, the ſine $\angle$NAD, the aberration, will be as ſine ADN. And becauſe AN is 10300 times as great as ND, therefore the ſine NAD does not differ from its arc or angle, and conſequently the angle of aberration NAD or ANB, is always as the ſine of the angle of the earth's way, ADN, or ANF. Hence the angle of aberration ANB is greateſt when AN is perpendicular to ND, and becomes nothing when ANF is nothing.

And ſince AN is to ND, as radius to 20″; therefore, when AN is perpendicular to ND, the $\angle$NAD, or ANB, will be 20″, which is the greateſt it can be. In other caſes it will be as rad. : ſine ANF, (the angle of the earth's way) :: 20″ to the aberration correſponding to that angle, which angle is always taken in the plane of aberration ADNF.

By reaſon of the aberration, if a ſtar was placed in the pole of the ecliptic, it would appear to deſcribe a circle of 40″ diameter round the pole in a year. Any other ſtar will appear to deſcribe a ſmall ellipſis in a year; the tranſverſe axis of which is 40″, and parallel to the ecliptic; and the conjugate axis thereof at right angles to the former, and leſs than it in the ratio of it to the ſine of the ſtar's latitude.

M. De La Caille, in his valuable Treatiſe of Aſtronomy, gives the following methods for finding the aberration in right aſcenſion and declination of a ſtar.

For the Aberration in right Ascension. Seek in the Aſtronomical tables that point of the ecliptic, which correſponds to the point of the equator marked by the right aſcenſion of the ſtar; this point (which call N) is always that wherein the ſun being found, the aberration makes the apparent right aſcenſion the leaſt. Take in the ſame tables the angle made by the ecliptic, and a meridian paſſing through that point N; and ſay, as the product of the radius by the coſine of the declination of a ſtar, is to the product of the coſine of the diſtance of the ſun from the point N, by the ſine of the angle between the ecliptic and meridian of N, ſo is 20″ to the aberration in right aſcenſion; and is additive or ſubtractive, according to the ſituation of the ſun to the point N, which is eaſy to determine.

For the Aberration in Declination. Take from the Aſtronomical tables the declination of the point N, and ſay as the ſum of the declinations of the ſtar and the point N (if of different names) or of their difference (if of the ſame name) is to the coſine of the right aſcenſion of the ſtar; ſo is the ſine of the obliquity of the ecliptic, to the co-tangent of an arc, which is the diſtance between the point N in the ecliptic, where the aberration in right aſcenſion makes his right aſcenſion the leaſt; and that point of the ecliptic (which call T) where the ſun is found, when the aberration in declination makes his declination the leaſt.

The point T is obtained by ſubtracting the arc found from the place of N, if the right aſcenſion of the ſtar is proceeding from 0° to 90° with ſouth latitude and north declination; or from 180° to 270° with north latitude and ſouth declination; or, T is found by adding this arc to the place N, if the right aſcenſion is between 270° and 90° with latitude and declination, both north; or between 90° and 270° with latitude and declination, both ſouth. On the contrary, the ſupplement of the ſaid arc from place N muſt be ſubtracted, if the right aſcenſion is between 90° and 180° with ſouth latitude and north declination; or is between 270° and 360° with north latitude and ſouth declination. Finally, the ſupplement of this arc from the place N muſt be added, if the right aſcenſion is between 270° and 90° with latitude and declination, both ſouth; or between 90° and 270° with latitude and declination, both north.

Then ſay, as the product of the radius by the ſine of NT, is to the product of the coſine of the diſtance of the ſun from the point T, by the ſine of the ſum, or difference, of the declination of the ſtar and point N, ſo is 20″ to the aberration in declination; which is eaſily applied to the true declination of the ſtar, according to its ſituation in regard to the ſun.

The effect of the aberration of light on the planets may be found thus. Say as the horary motion of the ſun, multiplied by the radius of the annual orbit of the earth, is to the diſtance of the earth from the planet multiplied by 20″; ſo is the horary motion of the planet, in longitude, in latitude, in right aſcenſion, or declination, to a quantity, whereby the aberration of light has diminiſhed ſuch longitude, latitude, right aſcenſion, or declination.

SECT. XII.

Of the irregular Motions of the Planets, the Methods of determining their Places, the Equation of Time, &c.

IN order to the underſtanding of the matters treated of in this Section, it will be proper to premiſe the following definitions.

I. The True Anomaly of a Planet, is the angle ASN (at the ſun S) comprehended between the aphelion A, and the planet N, in its orbit; or of a comet between it and the perihelion. See Plate IV. *Figure* 19.

II. The Mean Anomaly is an angle ASG, taken proportional to the time of the planet's moving from the aphelion A, to the place N, in its orbit. An arch of a circle, or the area ANS of the ellipſis, may alſo be taken for the mean anomaly.

This angle ASG increaſes uniformly with the time, or with the area ANS; and therefore the motion of SG, round the centre S, is called the Mean Motion.

III. The Equation of the Centre, is the $\angle$ NSG, or the difference between the True and Mean Anomalies. This is alſo named the *Proſthaphaereſſis*.

IV. The Heliocentric Place, Heliocentric Longitude, and Heliocentric Latitude of a Planet, are the planet's place, longitude, and latitude, as ſeen from the ſun.

V. If S be the ſun (*Figure* 20.) E, the earth; P, the planet, and PB perpendicular to the ecliptic. Then in the triangle EPS, or EBS, reduced to the ecliptic, the angle at the ſun ESP, or ESB, contained between the earth and the planet, is called the Angle of Commutation.

VI. The Angle of Elongation, is the angle at the earth PES, or BES, contained between the ſun and the planet.

VII. The Parallax of the Orbit is the angle at the planet, or its place in the ecliptic EPS, or EBS, contained between the ſun and earth. Here AE is the earth's orbit, NPC the planet's orbit, NB its orbit, reduced to the ecliptic, HSN, the Line of the Nodes, and N, the ascending Node.

VIII. The Curtate Distance of a Planet from the ſun or the earth, is the line SB or EB, drawn from the ſun or the earth, to the point where the perpendicular from the planet cuts the ecliptic. This is the diſtance of the planet from the ſun or the earth, reduced to the ecliptic.

IX. The Argument of Latitude, is the Angle at the ſun, NSP, between the Planet and its aſcending Node, reckoned in the planet's orbit, NPC.

X. The Radix is the place of a planet at ſome remarkable point of time, as the birth of Chriſt, the beginning of a particular century, &c. From this point all the motions are calculated as from a fixed foundation.

XI. Apparent or Solar Time, is the time as it is ſhewn by the ſun, and proceeds irregularly, by reaſon of the earth's motion, which is ſometimes quicker or ſlower than at other times.

XII. Mean or Astronomical Time, is the time that goes forward uniformly, without any acceleration or retardation. This is alſo called True Time.

XIII. An Astronomical Day, begins at the noon of the preceding day, and ends at the noon of the following day, the hours being reckoned from 1 to 24.

XIV. The Astronomical Year begins and ends on the laſt day of December, at *noon*, and theſe beginnings or endings are different, in different places according to the difference of longitude.

Proposition I. *Having given either the true Anomaly or the Diſtance of a Planet from the Sun, to find the other, and the Time when it will be in that Part of its Orbit correſponding therewith, as alſo the Mean Anomaly.*

Here the periodical time, the orbit of the planet, and the time of its being in its perihelion being ſuppoſed to be known, Mr. Emerſon has demonſtrated that if PNAB (*Figure* 21) be the orbit, S the ſun, C the centre, P the perihelion, A the aphelion, and if the ſemi-tranſverſe CP be put $= a$, ſemiconjugate CB$=c$, eccentricity CS$=n$, the diſtance of the planet SN$=y$; its periodic time t; coſine of Angle PSN$=z$, and D $=$ number of degrees in the arc whoſe coſine is $\frac{a-y}{n}$, and radius 1, that the time of the planets deſcribing the part of its orbit SPN will be truly exhibited by this expreſſion $\frac{Dt}{360} - \frac{t\sqrt{2ay-cc+yy}}{2a\times 3.1416}$. and if y $\left(\text{which is equal } \frac{cc}{a+zn}\right)$ is given, then z, or the true anomaly which is equal to $\frac{cc-ay}{ny}$, is alſo given; or if z, or the true anomaly be given, then y or the time of the planets arriving at N will be known; and the difference between this time and half the periodic time, will give the time of its moving from the aphelion.

If the planet in moving from the perihelion be paſt the aphelion, then the above expreſſion ſhews the time in which it will come to the perihelion again.

Alſo the mean anomaly will be equal to $D - \frac{57.29578\sqrt{nn-\overline{a-y}^2}}{a}$ reckoning from the perihelion.

Proposition II. *From the Mean Anomaly given to find the true Anomaly.*

By the laſt Propoſition, the Mean Anomaly is found directly from the true; but there is no direct way of finding the true Anomaly from the mean; but Mathematicians are obliged to have recourſe to methods of approximation.

The following Solution, by the late excellent aſtronomer and mathematician, Mr. G. **Witchel**, may be acceptable to our readers.

" To explain this, let ApHP, (Plate IV. *Fig.* 22) be the elliptic orbit of the planet, ACP the tranſverſe axis, HC the ſemi-conjugate, and S, the focus in which the ſun is placed; moreover, let A, p, and P repreſent any three places of the planet, at three given inſtants of time: then it will be, as the time of deſcribing the elliptic arc Ap, is to the time of deſcribing the elliptic arc pP, ſo is the trilinear area ApS, to the trilinear area pPS, and conſequently, the given area of the ſemi-ellipſe ApPA, is divided by the line pS, in the given ratio of the time of deſcribing the elliptic arc Ap, to the time of deſcribing the elliptic arc pP. To divide an ellipſis in this manner, is the famous Keplerian problem, which has exerciſed geometricians for almoſt two centuries.

SOLUTION.

" Let the ſemi-circle AGP be deſcribed upon the tranſverſe axis ACP, and through p, the place of the planet, let DpE be drawn, parallel to the ſemi-conjugate HC, meeting the ſemi-circle in the point E; join E,S, and the ſemi-circle will be divided by the line ES, in the ſame ratio, as the ſemi-ellipſe AHP is by the line pS, as is demonſtrated by the writers on conics; let E, C, be joined, upon which, produced if needful, let fall from S, the perpendicular SF; take the arc EM equal in length to the right-line SF, and join M,C: Then it is evident, that the area of the ſector ECM, will be equal to the area of the triangle ECS, and conſequently, the area of the ſector ACM, will be equal to the trilinear area ASE: hence the ſector AMC, or the angle ACM, will be proportional to the elliptic area ApS, which is called, the mean anomaly of the planet, as the angle ACE, is denominated, the **Eccentric Anomaly**, and the angle ASp, the true, or co-equate anomaly."

Mr. Witchel proceeds to find the eccentric anomaly, and from thence the true anomaly on principles which evince his profound knowledge in geometry, and concludes with the following

PRACTICAL RULE.

"It will be moſt convenient to have the eccentricity expreſſed in decimal parts of the ſemi-tranſverſe axis: that done, from the log. of the perihelion diſtance, ſubtract the log. of the aphelion diſtance, and let the remainder be called A; likewiſe to the log. of the eccentricity add the log. 1.758123 (being the log. of the number of degrees contained in an arc equal to the radius) and call the ſum B; to the log. A, add the log. tangent of half the mean anomaly, and the ſum will be the log. tangent of an arc; ſubtract this arc from half the mean anomaly, and to the log. ſine of the remainder add the log. 1.758123, and the ſum will be the log. of the difference of the mean and eccentric anomalies, very nearly: then if the mean anomaly be leſs than 180°, ſubtract this difference therefrom, otherwiſe add it thereto, and it will give the firſt value of the eccentric anomaly, which will be ſufficiently exact in each of the planets, except Mars and Mercury: in the former the error, when greateſt, will be about three-fourths of a ſecond; but in the latter, it will amount to one-third of a minute: in order therefore, to correct it, let the log. ſine of the eccentric anomaly, as found above, be added to the log. B, and the ſum will be the log. of the difference of the two anomalies to a ſtill greater exactneſs: then, if to the log. co-ſine of the eccentric anomaly, there be added the log. of the eccentricity, the ſum will be the log. of a fraction, which, if the eccentric anomaly is more than 270°, or leſs than 90°, muſt be added to unity, otherwiſe ſubtracted therefrom, and the ſum, or difference, will be a number, by which if the difference of the two values of the eccentric anomaly be divided, the quotient will be the error of the firſt value of the eccentric anomaly: then if the eccentric anomaly is in the firſt or third quadrant, let the error be ſubtracted therefrom, otherwiſe added thereto, and it will give the eccentric anomaly to a very great degree of exactneſs: laſtly, to the log. tangent of half the eccentric anomaly add half the log. of A, and the ſum is the log. tangent of half the true anomaly."

Mr. **Emerson** has demonſtrated the following Properties:

1ſt. That the aphelion diſtance, AS, is to the ſemi-conjugate CH, as the tangent of half the eccentric anomaly, ACE, to the tangent of half the true anomaly ASp.

2d. That the ſquare root of the aphelion diſtance S A is to the ſquare root of the perihelion diſtance SP, as the tangent of half the eccentric anomaly to the tangent of half the true anomaly.

3d. That the ſine of the true anomaly is to the ſine of the eccentric anomaly, as the ſemi-conjugate to the diſtance (Sp) of the planet from the ſun.

4th. And that the ſine of half the true anomaly is to the ſine of half the eccentric anomaly, as the ſquare root of the perihelion diſtance, SP, to the ſquare root of Sp, the diſtance of the planet from the ſun.

From the foregoing Propoſitions, Tables may be made for computing the place of a planet in its orbit.

Proposition III. *To find the Equation of Time, or the Difference between the true and apparent Time.*

All uniform motions are proportional to the times in which thoſe motions are performed: hence, if the times are given, the motions will be known, or if the motions are given, the times will be known, and conſequently the motions and times may be taken for the meaſures of one another; but ſince the motion of the earth (or apparent motion of the ſun) in its orbit, is not uniform, the apparent time will not be equable.

Likewiſe, as the ſun's apparent motion is not in the plane of the equator, but in an orbit inclined to it in an angle of 23° 28′, it will on that account alſo appear to move unequally therein, ſo that there are two cauſes that produce the inequality of natural days, to wit, the eliptical orbit of the earth, and its obliquity to the equator. To explain this, See Plate IV. *Figure* 23. Let ANP be the earth's orbit; S, the ſun, and let the area ASB be $=$ area PSD, then the areas ASB and PSD are deſcribed in equal times; and ſince AS is greater than PS, the arc PD is greater than AB. Conſequently the earth moves ſlower in the aphelion A, and quicker in the perihelion P, varying with an increaſed motion from A to P, ſo that at any place N, the angular motion is reciprocally as $\overline{SN}^2$

Now, ſuppoſe AB and PD to be deſcribed in times equal to that of the earth's rotation; then, when the earth has made an entire rotation about its axis, the meridian of any place will paſs through the ſame ſtar as it did at the beginning, when it was at A. But the earth in the ſame time having really (or the ſun apparently) moved through an arc of the ecliptic equal to AB, the ſame meridian does not paſs through the ſun, it being then parallel to AS; and therefore the earth muſt continue its revolution about its axis, through an angle equal to ASB, before it can overtake the ſun.

Again, the earth paſſing through PD in the time of its rotation, the meridian, being then parallel to PA, will not paſs through the ſun at S, but the earth muſt continue its rotation through the angle PSD, before the meridian overtakes the ſun.

Now the angle PSD, being greater than the angle ASB, and the earth's diurnal motion being uniform, the meridian will be longer in overtaking the ſun at P than at A, or, which is the ſame, the ſun will be longer in coming to the meridian at P than at A, and ſo the day (viz. including day and night) will be longer when the earth is in the perihelion than in the aphelion; and ſince the perihelion happens near the middle of winter, the natural days will be longer in winter than in ſummer.

Again, by the doctrine of centripetal forces, the mean motion round S will be equal to the true motion, when SN is equal to the ſquare root of the product of the ſemi-axis, and that happens in two points of the orbit.

Let AEPQ, (*Figure* 24) be the prime vertical; EQ, the equinoctial; EL, the ecliptic. Suppoſe the ſun, moving uniformly, to be at D, then the meridian, PDFA, being drawn through the point D, and the poles P and A, it is plain that when D is near C, the motion CD, along the ecliptic, is greater than that along the equinoctial CF, becauſe the hypothenuſe CD is greater than the baſe CF; but when D is near L, the motion along the equinoctial FQ is greater than that in the ecliptic DL; for the part DL, almoſt coinciding with a parallel circle, muſt be leſs than the correſponding part, FQ, of the great circle. Hence there is a point between C and L, where the motion along CL is equal to the motion in the equator, CQ, or, which is the ſame, where the motion of longitude is equal to the motion of right aſcenſion; but in all other points theſe two motions are unequal. After a quadrant of the ecliptic is deſcribed, they coincide at L and Q, and therefore they coincide at the equinoctial and ſolſtitial points.

Hence, the equation of time is effected by two cauſes, ſolely independent on each other. When they concur together, they increaſe this inequality; when they are of a contrary kind, they decreaſe it; and, in this caſe, when they are equal to each other, the inequality vaniſhes.

To find the equation of time anſwering to each ſeparate cauſe, proceed thus.

I. *For that depending on the Elliptical Orbit of the Earth.*

Find the true a anomaly from the mean, by a table computed for that purpoſe, according to Prop. II. the difference between the true and mean anomalies, converted into time, gives the equation of time; in which caſe obſerve, that from the aphelion to the perihelion, where they coincide, the mean place precedes the apparent place, but from the perihelion to the aphelion, the apparent place precedesthe mean; and conſequently, the equation of time will be additive or ſubtractive accordingly.

II. *For the Equation depending on the Obliquity of the Ecliptic.*

Let CD, in the aforeſaid figure, be the ſun's longitude; and let CI (in the equinoctial) be taken equal to CD. Then in the right-angled triangle, CDF, there are given the hypothenuſe CD, and the angle C, to find the right aſcenſion CF; then CF, taken from CD or CI, gives the difference FI, which converted into time, is the equation for the longitude CD: where note, that the mean place, I, precedes the apparent place, F, in the firſt and third quadrants of the ecliptic; but in the ſecond and fourth quadrants, the apparent place precedes the mean, and the equation of time reſulting from this cauſe, isadditive or ſubtractive accordingly.

The final, or total equation, as reſulting from both cauſes, is the ſum or difference of theſe equations, according as they are of like or different kinds, and is to be added or ſubtracted accordingly, as ſhall be denoted by the ſign of the greater of the two former equations.

PROPOSITION IV. *To find the Sun's Place and Diſtance at a given Time, by Aſtronomical Tables.*

Let $L =$ the ſun's mean place or longitude; $P =$ the place of the apogee; $A =$ the ſun's mean anomaly; $E =$ the equation belonging to the anomaly A, which is + or —; $G =$ the arc belonging to the equation of time, which is alſo + or —; and let $D =$ log. diſtance of the ſun, anſwering to the ſaid anomaly; then $L+E+C =$ ſun's true place, or $P+A+E+G =$ ſun's place, and the number anſwering to the log. D, is his diſtance.

PROPOSITION V. *To find the Place of a Planet at a given Time, by Aſtronomical Tables.*

Let $L =$ the planet's mean longitude or place; $F =$ the longitude of the aphelion; $L-F = A$, the mean anomaly; $E =$ the equation anſwering to A, which is + or —; $N =$ the place of the aſcending node; $L+E = H$, the heliocentric longitude; $H-N$, the argument of latitude; $R =$ the reduction belonging to $H-N$, which is + or —; then $L+E+R =$ the true heliocentric longitude.

Alſo, let $B =$ diſtance anſwering to A; $X =$ the heliocentric latitude; and $c =$ the curtation for $H-N$; then $B-C =$ curtate diſtance of the planet in the place of the ecliptic; and the difference of the longitudes of the earth and planet is the angle of commutation, or angle at the ſun; then in the triangle made by the ſun, earth, and planet, there are two ſides, and the included angle made at the ſun, given, to find the angle at the earth or angle of elongation, which added to or ſubtracted from the ſun's place, according as the planet's place or ſun's place is foremoſt, (which will appear by the conſtruction, if a figure is drawn) will give the Geocentric Place of the planet.

The Geocentric Latitude will be found by the following proportion:

As the ſine of the angle of commutation reduced to the ecliptic : ſine of the elongation : : tangent of the heliocentric latitude : tangent of the geocentric latitude.

PROPOSITION VI. *To find the Time when a Planet is ſtationary.*

If the orbits of the planets were exact circles, the time might be exactly found, but as they are elliptical, there is no direct method by which this buſineſs can be accurately performed; however, as their orbits do not widely differ from circles, we may approach near to the time, which may be corrected by repeated trials.

Mr. Emerſon has demonſtrated, that if AR, and CB, (Plate IV. *Figure* 25) be the orbits of two planets, both circular, and in the ſame plane; and S, the ſun in their common centre; and if the radius SA or SR be put $= r$, and the radius $SB = R$, then ſuppoſing one of them A, or B, to be the earth, and the other any planet, that ſuch planet will appear ſtationary to a ſpectator on the earth, when the coſine of the angle $ASB = \frac{\sqrt{Rr}}{R+r-\sqrt{Rr}}$, radius being 1. Wherefore, having the mean diſtances of the earth and planet, find, by the above Theorem, the angle at the ſun between the earth and planet, when it is ſtationary; and for the time when the planet is ſuppoſed to be ſtationary or nearly ſo, find the heliocentric places of the earth and planet, and you will have the angle between them, as it appears at the ſun; then if this angle be the ſame as the ſtationary angle found as above, the aſſumed time is the time required, nearly; but if not, find the number of days which the earth and planet have to move in their orbits, till they make that angle; which may be done thus: Let P be the periodic time of the planet, p that of the earth, and $x =$ number of days required. Then $P : 360° : : x : \frac{360x}{P}$, the arc run through by the planet; and as $p : 360° : : x : \frac{360x}{p}$, the arc run through by the earth; and the difference of theſe arcs or angles, muſt be put equal to the ſum or difference of the two former mentioned angles, as the caſe requires, which will give an equation from which x will be readily found, and ſo the time of their being ſtationary will be determined nearly; to correct which find the geocentric longitude of the planet for the day ſo determined, and alſo for the following day; if they happen to be the ſame, then the planet is ſtationary on one of theſe days; but if not, obſerve whether it is direct or retrograde. If it be direct, it is either ſhort of the firſt ſtation or paſt the ſecond. If it is retrograde, it is either paſt the firſt or ſhort of the ſecond ſtation. Wherefore you muſt accordingly take 3, 4, or more days, ſooner or later than this time as the caſe requires, and compute anew the geocentric longitude of the planet for that time and the day following; and if as before, theſe do not agree, a new time muſt be taken and their places computed again, till at laſt they are found to correſpond. Then, when you are within a day of the true time, compute the planets geocentric longitude for three ſucceſſive days; and ſo having the progreſs or regreſs of the planet for theſe times, the exact time of the planet's being ſtationary, may be found by the method of interpolation; for which ſee the word INTERPOLATION.

PROPOSITION VII. *Having given the Time of any one Tranſit of Mercury, or Venus, over the Sun's Diſk to find all the Times, wherein we may expect to ſee a Tranſit of the ſame Planet, when it is in the ſame Node.*

It is known from obſervation that the inferior planets, Mercury and Venus, ſometimes paſs over the ſun's diſk, and appear thereon as black ſpots. This phænomenon can only happen when the earth and planet are in or near the line of nodes, the planet being at the ſame time retrograde.

The ſun muſt be ſo near the node, as that his apparent ſemidiameter may exceed the geocentric latitude of the planet; for otherwiſe, it is evident the planet will not appear on his diſk.

Alſo, ſince the line of the nodes of each planet is nearly fixed in one place, the earth will be in the line of the nodes, always in or near the ſame point of his orbit; and hence, the planet being retrograde in the aſcending node, and the earth at that time in the line of nodes, the tranſits will conſtantly happen about the ſame time of the year; and the ſame for the deſcending node.

Now let $P =$ the periodic time of the earth; and p, the periodic time of the planet; then we have only to find two whole numbers as x and y, ſuch as that xP may be equal to yp, or that $\frac{p}{P}$ may be equal to $\frac{x}{y}$; that is, to find two whole numbers in the ſame ratio, or nearly ſo, as p and P.

For Mercury, thoſe numbers are $\frac{6}{25}$, $\frac{7}{29}$, $\frac{13}{54}$, $\frac{33}{137}$, $\frac{4}{191}$, &c. each ratio approaching nearer and nearer to the truth; the upper number (x) is the number of ſydereal years, in which a tranſit may be expected to return.

At the end of 6 years it rarely happens, but frequently at the end of 7. Alſo at the end of 13, 33, 46, or any additions made by them, a tranſit will probably happen. On November 12, 1782, there was a tranſit of Mercury, and at the diſtance of about 7 years, viz. on November 5, of the preſent year, there will be another. Alſo on May 4, 1786, there was a tranſit of Mercury, and at the diſtance of 13 years, viz. on May 7, 1799, there will be another, which are all that will happen in the preſent century.

For Venus, the numbers $\frac{x}{y}$ are $\frac{8}{13}$ $\frac{235}{382}$ $\frac{713}{1159}$ &c. therefore at the diſtance of 8 years, or 235 years, or 713 years, or their compounds, (though but ſeldom after 8 years) a tranſit of Venus will probably return. In 1639 on November 24, old ſtile, there was a tranſit of Venus, and at the diſtance of about 235 years, viz. on November 27 A. D. 1874, old ſtile there will be another, alſo on May 23, A. D. 1769 there was a tranſit of Venus, and on May 28, A. D. 1996, there will be another which are all that will happen before the expiration of the two following centuries.

PRO-

PROPOSITION VIII. *To find the exact Time of the Ingreſs and Egreſs of an inferior Planet, paſſing over the Sun's Diſk, and its neareſt Approach to the Sun's Centre.*

By the laſt propoſition find the time when the tranſit will nearly happen; and to that time find the place of the earth, and the planets heliocentric longitude: If theſe agree they are then in conjunction; but if not, the time of their conjunction muſt be found thus. Put P, p, for the periodic times of the earth and planet, reſpectively, then $\frac{360}{p} - \frac{360}{P} =$ the degrees which the planet gains of the ſun in a day, which put $= D$. Then ſay as $D^{\circ} : 1$ day : : difference between the earth's and planet's heliocentric places in degrees, to the time (in days) either to the conjunction, or paſt it, according as the earth or planet is foremoſt. But if that time ſhould prove to be not the time of the true heliocentric conjunction, the operation muſt be repeated till the true time is had, or the time may be found by the rule of falſe. Then having the heliocentric places of the earth and planet, the place of the node, and the diſtance between them, the daily or horary motions of both the ſun and planets, and the inclination of the orbit, which is the planet's path upon a fixed plane, the path of the planet on the moveable plane of the ſun's diſk may be eaſily found, as alſo its diſtance from the ſun's centre, when neareſt, and the time of the beginning and ending of the tranſit.

PROPOSITION IX. *To find the Quantity of Matter in any Body that has another revolving about it.*

Plate IV. *Figure* 25.

The quantity of matter in any central body, is as the cube of the diſtance of the revolving body directly; and the ſquare of the periodical time inverſly, by centripetal forces.

Let S be the ſun, E the earth, P a planet, T or Q a ſatellite, and let radius $PT = r$, periodical time of T or $Q = p$. Then the quantity of matter in the body P is as $\frac{r^3}{p^2}$, or $\frac{PT^3}{pp}$.

Now p or the periodic time is known for all the planets and ſatellites; and to find PT, let ST, EQ, be tangents to the orbit at T and Q; then PT is as $SP \times$ angle PST; or PQ, as $PE \times$ angle PEQ; becauſe theſe angles are very ſmall. Therefore $SP \times$ angle $PST = PE \times PEQ$. Now the greateſt elongation, or the angle PEQ is found by obſervation; and the heliocentric places of the planet P, and the earth E are known, by the theory of the planets. Therefore in the triangle ESP, two ſides ES, SP, and the included angle ESP are given to find EP. And EP being known, as alſo PS, the angle PST will be known; and from hence QT or TP. And therefore the quantity $\frac{PT^3}{pp}$ will be known which is proportional to the quantity of matter in P.

Therefore it will be, as rad. : PE : : S.QEP : PQ or PT.

Or elſe, PS : PE : : angle PEQ : angle PST the heliocentric elongation; and then as rad : PS : : S.PST : P T. Thus the diſtance of Venus from the Sun is known to be 723.4. And PT for Jupiter's 4th ſatellite, is found to be 12.508; for Saturn's 4th ſatellite 8.5084; for the Moon 3.0546. And p or the periodic time for Venus, is $224^d.7$; for Jupiter's 4th ſatellite, 16.687^d; for Saturn's 4th ſatellite, 15.944; and for the Moon, 27.322. Therefore $\frac{PT^3}{pp}$ for the Sun, Jupiter, Saturn, and the Earth, comes out 7497.8; 7.0255; 2.423; and .03817. Therefore the quantities of matter in the Sun, Jupiter, Saturn, and the Earth, are as 196420; 184.05; 63.48; and 1, reſpectively. This is ſuppoſing the ſun's parallax to be $10\frac{1}{2}$ ſeconds, and conſequently the angle, the radius of the moon's orbit, ſubtends at the ſun, 10′ 30″. If the ſun's parallax be more or leſs than $10'\frac{1}{2}$; the quantity of matter in the earth muſt be increaſed or diminiſhed in the triplicate of that ratio; the reſt remaining the ſame.

COR. I. The real diameters of the ſun and planets, are; for the Sun 10000, Saturn 790, Jupiter 996, Mars 57, the Earth 109, Venus 112, Mercury 40, the Moon 30.

COR. II. Hence the denſity of the ſun, and ſuch of the planets as have ſatellites, are; the Sun 100, Saturn $65\frac{1}{2}$, Jupiter 95, the Earth 393.

COR. III. The weight of a body at the ſurface of any planet, is as the denſity and diameter of the planet. And therefore is at the Sun 23.34, Saturn 1.208, Jupiter 2.209, and the Earth 1.

PROPOSITION X. *To find the Proportion between the Axis of the Sun or Planet, and its Equinoctial Diameter.*

Let $r =$ radius of the ſun or planet, $f =$ force of gravity on its ſurface, $v =$ verſed ſine of the arch deſcribed in 1 ſecond by its rotation, to the radius r. $H =$ equinoctial or greateſt radius. Then if the force of gravity f be denoted by the ſpace a heavy body deſcends in a ſecond at its ſurface, v will denote the centrifugal force ariſing from its revolving; and this is equal to the diminution of its gravity. But ſo much as the gravity of a column of the planet is diminiſhed, ſo much is its height increaſed, to make an equilibrium. And this is the ſame within the planet as at the ſurface; as both theſe forces decreaſe in the ſame ratio. Therefore we ſhall have $f : f - v : : H : r$. And $f : f - v : :$

$2H : 2r$; that is, $f : f - v : :$ as the equinoctial diameter : to the polar diameter nearly.

Therefore, if the diameter and time of revolution be known; the arc deſcribed in a ſecond will be known, and v the verſed ſine of that arc. Alſo f will be known, by having the gravitating force upon the ſurface. And hence, the ratio of the diameters will be found.

COR. In the earth, the ratio of the axis to the equatorial diameter, will be found as 285 to 286. And in Jupiter as 11′ to 12. In the ſun the difference is quite inſenſible. In the reſt of the planets, there wants the proper data.

With regard to the ſeveral irregularities and inequalities which take place in the *lunar theory*, they are ſo many, and affected with ſuch variations, that I chooſe rather to refer to thoſe authors who have made them their peculiar ſtudy, and have written particularly on the ſubject, than enter into the minutias of a matter ſo perplexed and intricate that there are ſcarce two writers who are perfectly of one opinion. The moſt diſtinguiſhed authors on this ſubject are Newton, Euler, De la Lande, Clairault and Mayer.

SECT. XIII.

OF COMETS.

Comets are ſo called from their having a long tail, ſomewhat reſembling the appearance of hair. Though this is not always the caſe; for ſome comets have appeared which were as well defined and as round as planets: but in general they have a luminous matter diffuſed around them, or projecting out from them, which to appearance very much reſembles the Aurora Borealis. When theſe appear, they come in a direct line towards the ſun, as if they were going to fall into his body; and after having diſappeared for ſome time in conſequence of their proximity to that luminary, they fly off again on the other ſide as faſt as they came, projecting a tail much greater and brighter in their receſs from him than when they advanced towards him; but, getting daily at a farther diſtance from us in the heavens, they continually loſe of their ſplendor, and at laſt totally diſappear. Their apparent magnitude is very different; ſometimes they appear only of the bigneſs of the fixed ſtars; at other times they will equal the diameter of Venus, and ſometimes even of the ſun or moon.

The true motion of comets was diſcovered from the obſervations made by Sir Iſaac Newton on the great comet of 1680. This deſcended almoſt perpendicularly towards the ſun, with a prodigious velocity; aſcending again with the ſame velocity retarded, as it had been before accelerated.

The many exact obſervations made on this comet enabled Sir Iſaac Newton to determine that they are a kind of planets which move in very eccentric ellipſis.

Dr. Halley collected all the obſervations he could on comets; and calculated the periodical times of 24 of them, on a ſuppoſition of their being parabolas; but afterwards found that they agreed better with the ſuppoſition of their motion being performed in very eccentritic elliptical orbits. On this he calculated a table of their elements; from which it was manifeſt that they were not comprehended in the zodiac, ſome of them making an angle of upwards of 80° with the ecliptic.

By computations founded on theſe elements, the Doctor concluded that the comet of 1682 was the ſame which had appeared in 1607 and 1531: that it had a period of 75 or 76 years; and he ventured to foretel, that it would return about the year 1758.

The comet which appeared in 1661, was ſuppoſed to be the ſame with that of 1532, and to have a period of 129 years; and, from the equality of periods, and ſimilitude of appearances, it was concluded that the great comet of 1680 was the ſame which had appeared in 1106, in the time of Henry I. and the conſulate of Lampadius and Oreſtes, about the year 531, and in the year 44 B. C. before Julius Cæſar was murdered; conſequently its period muſt be about 575 years.

Since the time of Dr. Halley, other aſtronomers have calculated the elements of 25 other comets; all of which, excepting one of three which appeared in 1759, and which differs but little from that of 1531, 1607, and 1682, and is therefore accounted the ſame, differ very much from each other; ſo that we cannot help concluding them all to be different, and that the number of theſe bodies is very great.

Though the orbits of all comets are either parabolas or very eccentric ellipſes, yet there are vaſt differences among them; for the planes of ſome comets are almoſt perpendicular to others, and ſome of their ellipſes are much wider than others. The narroweſt ellipſis of any comet hitherto obſerved was that of 1680. There is alſo a great inequality in the motion of comets, their velocity being incomparably greater in their perihelion than in their aphelion.

Aſtronomers are now generally agreed, that comets are opaque bodies, enlightened by the ſun; and of this opinion was Sir Iſaac Newton, for the confirmation of which, he obſerves, that if a comet be ſeen in two parts of its orbit, at equal diſtances from the earth, but at unequal diſtances from the ſun, it always ſhines brighteſt in that neareſt the ſun.

Their diſtance may be known from their parallax, according to which Sir Iſaac found the diſtance of the comet of 1577 to be about 210 ſemidiameters of the earth, its apparent diameter being ſeven minutes; whence alſo he concluded, that the true diameter of the comet was to that of the earth as 3 to 14.

Various conjectures have been formed reſpecting the tails of comets; though it is acknowledged by all, that they depend on the ſun ſomeway or other.

Sir Iſaac Newton was of opinion, that the tail of a comet is a very thin vapour which the head ſends out by reaſon of its heat: that it aſcends from the ſun juſt as ſmoke does from the earth: that as the aſcent of ſmoke is cauſed by the rarefaction of the air wherein it is entangled, cauſing ſuch air to aſcend and carry the ſmoke up with it, ſo the ſun's rays acting upon the comet or atmoſphere of the comet, do by rarefaction and refraction heat the ſame; that this heated atmoſphere heats, and by heating rarefies, the æther that is involved therein; and that the ſpecific gravity with which ſuch æther tends to the ſun, is ſo diminiſhed by its rarefaction, that it will now aſcend from him by its relative lightneſs, and carry with it the reflecting particles whereof the tail is compoſed.

The near approach of ſome comets to the ſun ſubjects them to intenſe and inconceivable degrees of heat. Newton calculated that the heat of the comet of 1680 muſt have been near 2000 times as great as that of red hot iron. The calculation is founded upon this principle, that the heat of the ſun falling upon any body at different diſtances is reciprocally as the ſquares of thoſe diſtances; but it may be obſerved, that the effect of the heat of the ſun upon all bodies near our earth depends very much on the conſtitution of thoſe bodies, and of the air that ſurrounds them.

Indeed, according to his calculation, the comet of 1680 muſt be for ever in a ſtate of violent ignition. He hath computed that a globe of red-hot iron of the ſame dimenſions with the earth, would ſcarce be cool in 50,000 years. If then the comet be ſuppoſed to cool 100 times faſter than red-hot iron, as its heat was 2000 times greater, it muſt require upwards of a million of years to cool it. In the ſhort period of 575 years, therefore its heat will be ſcarce diminiſhed; and, of conſequence, it muſt now be in a ſtate of ignition very little inferior to that of the ſun itſelf. Sir Iſaac Newton hath farther concluded, that this comet muſt be conſiderably retarded in every ſucceeding revolution by the atmoſphere of the ſun within which it enters; and thus muſt continually come nearer and nearer his body, till at laſt it falls into it. This, he thinks, may be one uſe of the comets, to furniſh fuel for the ſun, which otherwiſe would be in danger of waſting from the continual emiſſion of its light.

He adds, that for the conſervation of the water and moiſture of the planets, comets ſeem abſolutely requiſite; from whoſe condenſed vapours and exhalation all the moiſture which is ſpent in vegetation and putrefaction, and turned into dry earth, &c. may be reſupplied and recruited; for all vegetables grow and increaſe wholly from fluids; and again, as to their greateſt part, turn by putrefaction into earth; an earthy ſlime being perpetually precipitated to the bottom of putrefying liquors. Hence the quantity of dry earth muſt continually increaſe, and the moiſture of the globe decreaſe, and be quite evaporated, if it have not a continual ſupply from ſome part or other of the univerſe. "And I ſuſpect (adds our great author), that the ſpirit, which makes the fineſt, ſubtileſt, and beſt part of our air, and which is abſolutely requiſite for the life and being of all things, comes principally from the comets."

Mr. Whiſton, from Flamſtead's meaſure of its apparent diameter, concluded the nucleus of the comet to be about ten times as big as the moon, or equal to a fourth part of the earth, and attributed the univerſal deluge in the time of Noah to the near approach thereof. His opinion was, that the earth paſſing through the atmoſphere of the comet, attracted therefrom great part of the water of the flood; that the nearneſs of the comet raiſed a great tide in the ſubterraneous waters, ſo that the outer cruſt of the earth was changed from a ſpherical to an oval figure; that this could not be done without making fiſſures, and cracks in it, through which the waters forced themſelves by the hollow of the earth being changed into a leſs capacious form; that along with the water thus ſqueezed up on the ſurface of the earth, much ſlime or mud would riſe; which, together with the groſſer part of the comet's atmoſphere, would, after the ſubſiding of the water, partly into the fiſſures and partly into the lower parts of the earth to form the ſea, cover all over the antediluvian earth, to a conſiderable depth.

The ſame comet he thought would probably, when coming near the earth, and heated in an immenſe degree in its perihelion, be the inſtrumental cauſe of that great cataſtrophe, the general conflagration foretold in the ſacred writings.

The analogy between the periodical times of the planets and their diſtances from the ſun, diſcovered by Kepler, takes place alſo in the comets. In conſequence of this, the mean diſtance of a comet from the ſun may be found by compairing its period with the time of the earth's revolution round the ſun. Thus the period of the comet that appeared in 1531, 1607, 1682, and 1759, being about 76 years, its mean diſtance from the ſun may be found by this proportion: As 1, the ſquare of one year, the earth's periodical time, is to 5776 the ſquare of 76, the comet's periodical time; ſo is 1,000,000, the cube of 100 the earth's mean diſtance from the ſun, to 5,776,000,000, the cube of the comet's mean diſtance. The cube root of this laſt number is 1794, the mean diſtance itſelf in ſuch parts as the mean diſtance of the earth from the ſun contains 100. If the perihelion diſtance of this comet, 58, be taken from 3588 double the mean diſtance, we ſhall have the aphelion diſtance, 3530, of ſuch parts as the diſtance of the earth contains 100; which is a little more than 35 times the diſtance of the earth from the ſun. By a like method, the aphelion diſtance of the comet of 1680 comes out of 138 times the mean diſtance of the earth from the ſun, ſuppoſing its period to be 575 years; ſo that this comet, in its aphelion, goes more than 14 times the diſtance from the ſun that Saturn does.

A TABLE of the ELEMENTS of the principal COMETS which have hitherto been duly obſerved.

Comet of A. D.	Place of Aſcending Node.				Inclination of Orbit.			Place of Perihelion.				Perihelion diſtance from ⊙ the diſt. of ⊕, being 1.	Mean Time of the Perihelion.			Motion.

As the orbits of all comets are either parabolas or ellipſes (though probably they are all ellipſes); and as their elliptical orbits are ſo very eccentric, that they approach exceedingly near to parabolas, aſtronomers, for the eaſe of computation, generally make their calculations on comets, as if their orbits were actually parabolas.

On this ſuppoſition, Mr. Emerſon, in his Aſtronomy, has demonſtrated that the times in which different comets move through ſimilar parts of their orbits, are as the ſquare roots of the cubes of their perihelion diſtances; that if a comet's perihelion diſtance be equal to the mean diſtance between the ſun and earth, it will deſcribe a quadrant of its orbit in 109 days, 14 hours, 46 minutes, and 12 ſeconds; and that if p be put = the perihelion diſtance of any comet, the time of its moving from its perihelion to the 90° of its orbit, will be $109.615p\sqrt{p}$ days.

Mr. Emerſon has alſo ſhewn, that if PNO (Plate IV. *Figure* 26) be the orbit of a comet, S, the ſun, P the perihelion, N the place of the comet. And if the perihelion diſtance SP be put $=p$, comet's diſtance SN $=y$, coſine of true anomaly PSN $=z$, and $v =$ verſed ſine of the ſupplement thereof. Alſo if 109.615 days, the time of a comet's deſcribing a quadrant whoſe perihelion diſtance is 1, = mean diſtance of the earth be put $=t$; and D = time of the perihelion; then will the diſtance $y = \frac{2p}{1+z} = \frac{2p}{v}$; the time from the perihelion, D, $= \frac{\overline{2p+y} \times t}{4} \sqrt{y+p}$; and the area PSN $= \frac{2p+y}{3} \times \sqrt{py-pp}$. Alſo if c be the coſine of half the true anomally, then the comets diſtance $y=\frac{p}{cc}$, radius being 1.

Note, the comet's orbit and the time of the perihelion are here ſuppoſed to be known.

Hence a table may be made for finding when a comet will be in any given part of its orbit, or, on the contrary, for finding in what point of its orbit it will be in at any given time.

N. B. In Section VII. I have ſhewn how to determine the orbit of a planet, but there is no ſuch direct method for finding the orbit of a comet; and therefore Aſtronomers uſually feign an orbit at pleaſure, and examine how it agrees with the motions of the comet, as determined by obſervation; and if they find it differ therefrom, they aſſume another orbit, and ſo on by trial, till at laſt they meet with one that will give the comet's place, &c. at any propoſed time, according to obſervations; and thence they conclude that ſuch orbit is the true one.

M. de la Caille has ſhewn, that if t be put for the tangent of half any true anomally of a comet, moving in a parabolic orbit; a, for the time it is in going from the perihelion to 90°, and b, for the time in paſſing from the perihelion to any aſſigned point in its orbit; alſo the diſtance of the comet from the ſun in its perihelion being ſuppoſed 1, and the times a and b, being given, that the tangent of half the true anomally will be found by extracting the root of the following cubic equation, viz. $t^3+3t=\frac{4b}{a}$; and therefore by ART. XXV. of our New Syſtem of ALGEBRA, t will be found $=\overline{\frac{2b}{a}+\sqrt{\frac{4b^2}{a^2}+1}}\Big|^{\frac{1}{3}}-\frac{9}{\overline{\frac{2b}{a}+\sqrt{\frac{4b^2}{a^2}+1}}\Big|^{\frac{1}{3}}}$.

The degrees, &c. anſwering to the tangent t, being doubled, will give the true anomally; and when the comet is direct, that being added to or ſubtracted from the place of the comet in its perihelion, according as the comet is paſt or ſhort of the perihelion, will give its true heliocentric place in its orbit; or, if it is retrograde, the ſame muſt be ſubtracted from or added to the perihelion place, according as the comet's place precedes or ſucceeds the place of the perihelion.

In order to calculate the place of a comet at any time propoſed, as ſeen from the earth, obſerve the following directions.

1ſt. Having the perihelion diſtance of the comet, find the time in which it will go through 90° of its orbit, and from thence the true anomally, or angle from the perihelion, anſwering to the given time; then adding, or ſubtracting the ſame (as the caſe ſhall require) from the place of the perihelion, its true heliocentric place in its orbit will be had.

2d. Subtract the place of aſcending node from the comet's true heliocentric place, and the remainder will be the argument of the comet's latitude; then ſay, as radius is to the coſine of the inclination of the comet's orbit, ſo is the tangent of the argument of latitude to the tangent of the comet's diſtance from the aſcending node meaſured in the ecliptic, which added to the true place of the comet's node, the ſum will be the comet's true heliocentric place reduced to the ecliptic; and as radius : ſine of argument of latitude :: ſine inclination of the comet's orbit : ſine of its latitude ſeen from the ſun.

3d. Calculate the ſun's diſtance from the earth and his true place from Aſtronomical Tables: from this ſubtract 6 ſigns, and the remainder will be the place of the earth, as ſeen from the ſun; then the difference between the comet's true heliocentric longitude in the ecliptic, and the longitude of the earth, will give the angle at the ſun between the earth and comet.

4th. Add the logarithm of the comet's perihelion diſtance to twice the logarithm of radius (or 20.0000000) and from the ſum ſubtract twice the coſine of half the comet's true anomally, and the remainder will be the logarithm of its true diſtance from the ſun.

5th. Say as radius : coſine of the comet's latitude ſeen from the ſun :: comet's real diſtance from the ſun, to its abridged diſtance, or diſtance meaſured upon the plane of the ecliptic.

6th. Then as the ſum of the comet's abridged diſtance, and of the earth's real diſtance from the ſun, is to their difference, ſo is the tangent of the complement of half the angle at the ſun (found by ART. III.) to the tangent of an arc, which added to this complement, if the comet's abridged diſtance exceed the earth's real diſtance from the ſun, or ſubtracted, if the comet's diſtance is leſs than the earth's, will give the angle at the earth, comprehended between the ſun's place and the comet's geocentric place, and from thence may be deduced the comet's geocentric place; for the ſun's place + or — this angle, according as the comet is before or behind the ſun in the ecliptic, will give the comet's *true geocentric longitude*.

7th. As the ſine of the angle at the ſun (found by ART. III.) is to the ſine of the angle at the earth (found by ART. VI.) ſo is the tangent of the comet's latitude as ſeen from the ſun, to the tangent of its latitude as ſeen from the earth, or *geocentric latitude*.

SECT. XIV.

THE CAUSE OF ECLIPSES OF THE SUN AND MOON, WITH METHODS OF DETERMINING WHEN THEY HAPPEN, AND RULES FOR CALCULATING THE TIME OF THE MOON's SOUTHING, RISING AND SETTING, &c.

THE earth and moon being opake bodies, and deriving their light from the ſun, do each of them caſt forth a ſhadow as it were behind them, or towards the oppoſite or contrary hemiſphere, to that in which the ſun appears.

And as light is propagated in right lines, and the earth and moon are nearly ſpherical, ſuch ſhadow will terminate in a point and occupy a conical ſpace. Now when either the moon or earth paſſes through the ſhadow of the other, it is thereby deprived of illumination from the ſun, and by degrees becomes inviſible to a ſpectator on the body from whence the ſhadow iſſues; and ſuch ſpectator will obſerve an eclipſe of that body which is paſſing through the ſhadow. Alſo a ſpectator on the earth or moon, when paſſing through the ſhadow of the other, will obſerve an eclipſe of the ſun, by reaſon of its being deprived of the ſun's light; ſo that in reality the eclipſe, in this caſe, is not an eclipſe of the ſun, but of the body itſelf.

To explain this more clearly, let AB (Plate IV. *Figure* 27.) be a luminous body, as the ſun, CD an opake ſpherical body expoſed to its light; and let AC and BD be drawn, interſecting each other in P, ſo will the cone CDP repreſent the ſhadow of CD. Now within this ſhadow, no light can come from the luminous body AB. Alſo let there be drawn BCE and ADF; then the ſpace ECPDF will be the penumbra, ariſing from the ſhadow of CD; into which ſpace ſome light comes from part of the body AB; thoſe parts of it which are neareſt the ſhadow being leſs illuminated than thoſe which are more remote, by reaſon that ſuch parts receive a leſs portion of rays from the illuminating body.

If any opake body, as G, be near the ſhadow CDP, then if part of it enters the ſhadow, ſuch part will be totally dark; and that part which remains in the penumbra, will have ſome faint light; thoſe places, however, which are the fartheſt from DP, having the moſt light. Conſequently the body G will then be eclipſed, either partially or totally.

If the centre of the body G paſs through the axis of the cone CDP, it will be centrally eclipſed; and if its diameter be leſs than the diameter of the conical ſhadow in that place, it will be totally eclipſed. Therefore, if AB be the ſun, CD the earth, moving in its orbit, and G the moon revolving about the earth; then, as the moon G advances towards an oppoſition of the ſun, or a full moon, it will come nearer to the ſhadow of the earth CDP; and if the moon is ſo near her nodes as to paſs through the ſhadow, ſhe will be eclipſed. If the moon's orbit was in the plane of the ecliptic, or earth's orbit, ſhe would be centrally eclipſed every full moon. Alſo when the moon by revolving in her orbit comes to the oppoſite ſide at H, where it is new moon, ſhe being then between the ſun AB and earth CD, will, in like manner, caſt a ſhadow upon the earth, and thereby cauſe an eclipſe of the earth, or an apparent eclipſe of the ſun. But the diameter of the moon being conſiderably leſs than the earth's diameter, and conſequently much more ſo is that of her ſhadow, at the diſtance of the earth, ſhe can never totally eclipſe the earth; ſo that in every eclipſe of the ſun (or earth) there will be many parts of the globe that will ſuffer no eclipſe at all, even though the ſun may be above the horizon. A ſpectator on any part where the ſhadow comes will be ſenſible of an eclipſe, if the ſun be then above the horizon of that place; alſo, as I have obſerved in regard to the moon, ſo here in reſpect of the earth, if the moon and earth were in one plane, there would be a central eclipſe of the ſun or earth at every conjunction of the ſun and moon, (or new moon); but that being not the caſe, an eclipſe of the ſun or moon can only happen when the moon at her conjunction or oppoſition is in or near to either of her nodes, or points where the plane of her orbit interſects the orbit of the earth.

As the earth is conſiderably greater than the moon, and even at the diſtance of the moon the diameter of its ſhadow is equal to thrice the moon's diameter; therefore, it frequently happens, that the moon becomes totally eclipſed, and continues to be ſo for ſome time.

Every eclipſe of the moon begins on the eaſtern and goes off on her weſtern ſide; for the moon's motion being ſwifter than the earth's, ſhe overtakes the ſhadow, and with her eaſtern limb enters into it on the weſt ſide, as ſhe proceeds eaſtward; but eclipſes of the ſun begin on the weſtern ſide, for the moon being then in the oppoſite part of her orbit, and overtaking the earth, the earth enters into her ſhadow on the weſtern ſide.

If the atmoſphere be ſerene, every eclipſe of the moon is viſible at the ſame inſtant, to all the inhabitants of that ſide of the globe to which ſhe is oppoſite; for as part of the moon's body at leaſt will enter the ſhadow, it muſt be, that every ſpectator to whom ſhe is viſible, will be ſenſible of the darkneſs which comes on that part; but with regard to eclipſes of the ſun, they do not happen to all places at the ſame inſtant; for the moon's ſhadow paſſing over the earth eclipſes different parts of it progreſſively, ſo that when it is ending at one place it is beginning at another; and in ſome places there is no eclipſe at all; and this even ſuppoſing the ſun to be viſible at each place all the while.

If, when the moon is in conjunction and near the node, her conical ſhadow does not reach the earth, but terminates at a leſs diſtance, then, ſince nothing but the penumbra falls upon the earth, there will be no total darkneſs on any part thereof; but to a ſpectator, ſituate at or near the point where the axis of the cone (produced) cuts the earth, the moon will appear with a bright ring ſurrounſting her, which ring is the edge of the ſun appearing all around the circle of the moon; the moon's apparent diameter being then leſs than the ſun's. This is called an annular eclipſe.

The duſky red light with which the moon ſometimes appears when eclipſed, is owing to the refraction of the rays of light paſſing through the earth's atmoſphere, and falling upon the moon.

No eclipſe of the moon can happen, but when the diſtance of the centres of the moon and of the earth's penumbra is leſs than the ſum of their ſemidiameters; for, if the diſtance be greater, the moon and penumbra cannot touch each other. Therefore, in lunar eclipſes, the moon's latitude muſt be leſs than the ſum of the ſemidiameters of the moon and penumbral ſhadow of the earth taken at the moon's orbit.

Alſo no eclipſe of the ſun (with reſpect to a particular place) can happen, unleſs the diſtance of the centres of the ſun and moon be leſs than the ſum of their ſemidiameters; but that there ſhall be none in any place, it is only neceſſary that the ſaid diſtance be leſs than the above ſum added to the moon's parallax.

Hence, in eclipſes of the ſun (taken generally) the moon's latitude muſt be leſs than the ſum of the ſemidiameters of the ſun and moon, and the moon's horizontal parallax; but that it may be viſible in a certain place, the parallax muſt be excluded.

The Requiſites belonging to an Eclipſe of the Moon.

I. In an eclipſe of the moon, half the angle of the cone of the earth's ſhadow, viz. $\frac{1}{2}\angle CPD = \angle CPO$ is equal to the ſun's apparent ſemidiameter, leſs his horizontal parallax.

II. Half the angle of the earth's penumbral cone, or $\frac{1}{2}\angle CHD = \angle CHO$, is equal to the ſum of the ſun's apparent ſemidiameter, and his horizontal parallax; and conſequently the ſaid half angle is equal to half the angle of the dark cone (or $\frac{1}{2}\angle CPD$, or CPO) added to the ſun's horizontal parallax.

III. The apparent ſemidiameter of the earth's dark ſhadow at the moon's orbit, is equal to the ſum of the horizontal parallaxes of the ſun and moon, leſs the ſun's apparent ſemidiameter.

IV. The apparent ſemidiameter of the earth's penumbra at the moon's orbit, is equal to the ſum of the horizontal parallaxes of the ſun and moon, together with the ſun's apparent ſemidiameter.

V. To find the length of the ſhadow OP, there are given in the triangle COP, the $\angle P =$ ſun's apparent ſemidiameter, leſs his parallax, and CO the earth's radius, to find $P\odot$.

PROPOSITION I. *To find the ∠ that the Moon's Way makes with the Ecliptic.* (Plate IV. *Figure* 28.)

Here the inclination of the moon's orbit are ſuppoſed to be known, and the horary motions of the ſun and moon.

Let NS be the ecliptic; NM, the moon's orbit; and let S be the ſun in the ſun's eclipſe, or the centre of the earth's ſhadow in an eclipſe of the moon; and M the moon at the time of the ſyziges. Take NA to NS as the ſun's horary motion to the moon's at that time, and draw MA, the moon's apparent orbit; ſo will the angle MAS be the angle required.

For by the conſtruction, in the time that the moon is in moving from N to M (that is through NS reckoned in the ecliptic) the ſun moves through a ſpace DS equal to NA. Therefore the ſun is in D, when the moon is in the node at N. Let there be drawn DB parallel to SM, and MB parallel to SD; and join BN, which will be parallel to MA. Now ſince the moon makes the ſame latitude DB or SM in the ſame time whether the ſun moves or ſtands ſtill; and ſince SM is her latitude when the ſun is at S, DB (=SM) will be her latitude, ſuppoſing the ſun ſtationary at D without any motion towards S, and conſequently NB will be her apparent way to an eye at D, through which ſhe ſeems to move in the ſame time; or which is the ſame, AM will be her apparent way to an eye fixed at S; for the triangles AMS and NBD are equal, and ∠ MAS is the angle of her way with the ecliptic. By the theory of relative motions in bodies moving the ſame way, all the apparent motions are the ſame, as if one body ſtood ſtill, and the other moved forward with a motion equal to the difference of their motions: and here ND or AS is the difference of their motions ſuppoſing S to be fixed. Hence the following proportions: as the moon's horary motion : ſun's horary motion :: SN, the diſtance from the node, to AN. Then SA=SN—AN.

And as ſine of SA : radius :: tangent of moon's latitude : tangent of ∠ A or the angle of the moon's way.

N. B. It is the apparent orbit AM that muſt be uſed in calculating the ſeveral particulars of an eclipſe, becauſe an obſerver conſiders not S as moving, and therefore only the relative motions are concerned.

PROPOSITION. II. *To calculate an Eclipſe of the Moon.* (Plate IV. *Figure* 29.)

I. Find the true time of the oppoſition, or full moon, when an eclipſe it to happen, by aſtronomical tables, the precepts for which are generally given along with the tables; and let that time be reduced to apparent time, by increaſing or diminiſhing the ſame, by the equation of time, as occaſion requires.

II. From aſtronomical tables calculate the true places of the ſun and moon when in oppoſition, as alſo the ſun's mean anomally, and the place of his apogee, together with the place of the moon's aſcending node, the place of her apogee, and her latitude.

III. Let NS be a part of the ecliptic, NM the moon's orbit; S, the centre of the earth's ſhadow, and M, the moon when in oppoſition. Take NA to NS as the ſun's horary motion to the moon's, and draw AM for the way of the moon from the ſun. Then in the right angled ſpherical triangle ASM, there are given AS (=NS—NA) and SM, the moon's latitude, to find the angle SMA.

IV. Let fall SP perpendicular to AM. Now ſince the arches SM, MP, and SP, are very ſmall, they may be taken for right lines, and the triangle SMP for a plane triangle without any ſenſible error. Then having SM and angle SMP, MP and SP may be found; P, being the place of the moon in the middle of the eclipſe. Likewiſe the time of the moon's moving through MP will be known by the horary motion, and from thence the time when ſhe is at P, or the middle of the eclipſe.

V. From aſtronomical tables find the ſun and moon's apparent ſemidiameters, for the time of oppoſition, and their horizontal parallaxes.

VI. From any convenient ſcale of equal parts with the centre P and radius PB, (equal to the minutes contained in the moon's radius) deſcribe the circle BC*o*, for the moon: and with the radius SD, (equal to the ſum of the ſun and moon's horizontal parallaxes, leſs the ſun's ſemidiameter in minutes) deſcribe the circle DEB, from the centre S, then this circle will repreſent the earth's dark ſhadow. Likewiſe from the ſame centre S, and with the radius SF (equal to the ſum of the ſun and moon's parallaxes added to the ſun's ſemidiameter in minutes) deſcribe the circle FQG, and it will repreſent the earth's penumbra. Then the ſeveral requiſites may be found nearly by ſcale and compaſſes: or by calculation; thus: To find when the moon firſt touches the penumbra at L, there are given in the right angled triangle SPK, SP, and SK, (the ſum of the radii SL and PB) to find PK; which being known the time of the moon's paſſing through it will be known, by her horary motion from the ſun.

And to find when the moon firſt enters the dark ſhadow at D, there are given SP, and SI (the ſum of the radii SD and PB) of the right angled triangle SPI, to find PI, and conſequently the time of half the duration in the ſhadow. Alſo to find the digits or 12th parts of the moon eclipſed, $Pn + Po - SP = no$, the part eclipſed, and $\frac{6\,no}{Po} =$ the number of digits eclipſed.

But in total eclipſes of the Moon, the earth's ſhadow is often much wider than the moon, and then more than 12 digits are ſaid to be eclipſed, and that, in proportion to ſuch exceſs.

Now the times of paſſing through PI, PK, &c. being known, as alſo the time of the middle of the eclipſe, at P, the beginning and ending thereof will be conſequently known.

PROPOSITION III. *To find the Way of the Moon from the Sun, in a Solar Eclipſe, ſuppoſing the Obſerver at reſt.*

Let HZO, (Plate IV. *Figure* 30) be the meridian of the place, HO, the horizon; EC, the equinoctial; EL, the ecliptic; Z, the zenith; P, the pole; S and M the places of the ſun and moon in conjunction; and PSD, the ſun's meridian.

Then having found the ſun's diſtance from the node NS, and the moon's latitude SM, &c. take NA to NS as the ſun's horary motion to the moon's horary motion; and thence SA will be known; and having drawn MA, there will be given SA and SM of the ſpheric triangle ASM, right angled at S, to find ∠ SMA; AM, being the moon's way from the ſun.

But becauſe the eye of the obſerver is in motion, through the earth's rotation, which gives an apparent motion to the moon, contrary to that of the obſerver, the quantity and direction of that motion muſt be found.

Now ſince the obſerver is carried eaſtward towards the point C, the apparent motion of the moon will be in the line CS; and to determine the poſition of CS in reſpect of AM, there are given ES and ∠E of the right angled triangle EDS to find DS and ∠ESD or ASP. And in the triangle ZPS there are given PS or complement of DS, the angle ZPS, (from the hour of the day) and ZP, the complement of the latitude, to find ZS, and angles PZS and ZSP. Then ∠ZSP, and ∠ASP, being known, ∠ZSA will be known; and MSA being a right angle, ZSM will be known. Alſo in the right angled triangle CFS, there are given CF, the meaſure of the angle FZC or difference between the angle PZS and the right angle CZP, and SF, the complement of ZS, to find CS and ∠CSF or BSZ; then ∠BSZ and ∠ZSM being known, ∠BSM will be known; and ∠SMA being known, the ſupplement thereof, SMB, is conſequently known, and hence alſo ∠ SBM.

To find the quantity of the motion. That along at M is already known; and with regard to the apparent motion along SB; the ſine of 15° (the horary motion of a point in the equinoctial) is .259 to the radius 1. And if b be the moon's horizontal parallax, then the radius of the earth appears at the moon under the angle b, and therefore 15° of the equinoctial appears under the angle of $.259\,b =$ the horary motion of a point in the equinoctial viewed directly from the moon = the moon's apparent motion ſeen from that point in the equinoctial; but this motion muſt be diminiſhed on two accounts; 1. becauſe it is leſs in a parallel circle in proportion to the coſine of the latitude, and 2dly on account of the obliquity of the motion when not perpendicular to the rays of the ſun, and this will be as the ſine of CS, the ſun's diſtance from the eaſt or weſt points of the horizon. Therefore to find the quantity of this motion, to the log of $.259b$, add the coſine of the latitude, and the ſine of CS. and the ſum abating twice radius is the log of this apparent motion. Then this motion muſt be compounded with the motion along AMB, thus:

Let AS (Plate IV. *Figure* 31) be a portion of the ecliptic, SB the way of the apparent motion, MA the moon's way from the ſun. Draw NM parallel to SB, and let MN be the horary motion along SB or MN, and MI the horary motion of the moon from the ſun. Complete the parallelogram NMIQ, and draw the diagonal MQR, which is the direction of the motion compounded of the obſerver's and the moon's motions, and MQ is the total apparent motion, ſuppoſing the obſerver at reſt.

Then in the plain triangle QMI, there are given MI and IQ, (or MN) and $\angle MIQ = MBS$, to find $\angle QMI$, and ſide QM, or the abſolute horary motion. Then the angles QMI and IMS, being known, $\angle QMS$ is alſo known.

It muſt be obſerved, that if the ſun be in the Eaſtern hemiſphere, in which caſe the concave ſide of the Eaſtern hemiſphere is here projected in (Plate IV. *Figure* 30) then the moon's motion from the ſun is from M towards A, and the other apparent motion is from S towards B, or from M towards N. But if the ſun is in the weſtern hemiſphere, this projection repreſents the convex ſide of the ſphere, and then the moon moves from the ſun in the direction AM, and the other apparent motion is from S towards C, being contrary.

PROPOSITION IV. *To calculate an Eclipſe of the Sun for a particular Place given.*

I. By aſtronomical tables find the true time of the conjunction or new moon, and the places of the ſun and moon at that time, with all the other requiſites, adapted to the particular place.

II. Having found the way of the moon from the ſun, as directed in the laſt Propoſition, find, by the aſtronomical tables, the moon's horizontal parallax, her apparent diameter, and horary motion, as alſo the ſun's apparent diameter, and his horary motion.

To avoid trouble, if the ſphere be projected on a large ſcale, it will give the requiſites with tolerable exactneſs, without calculation, by meaſuring the ſeveral angles and ſides; and here it is beſt to project the concave ſide, for then every thing appears as it is in nature.

III. Find the moon's parallax of altitude, by making as rad. : coſ. altitude : : moon's horizontal parallax : her parallax of altitude Vt or Mm. Alſo find her parallax of latitude Mn, and longitude Ss or mn, by PROB. XVII. SECT. VII, and from thence her apparent latitude and longitude will be known.

IV. Draw the line ASL for the ecliptic, and from a large ſcale of minutes erect SM perpendicular to AS, and equal to the apparent latitude; make the angle SMR, as found in the laſt Propoſition; and draw NMR, for the moon's apparent path. From S let fall SP, perpendicular to MR, and SP will be the leaſt diſtance of the centres of the ſun and moon, or the middle of the eclipſe. From the centre S with the radius equal to the minutes contained in the ſun's ſemidiameter, deſcribe the circle ABC for the ſun; and from the centre P, with the radius equal to the moon's ſemidiameter, deſcribe the circle AOCD for the moon. If theſe circles do not intereſt, there will be no eclipſe: but if they interſect, an eclipſe muſt neceſſarily happen.

V. P is the place of the moon, in the middle of the eclipſe. Make SI and SK = ſum of the ſemidiameters of the ſun and moon, and the moon's centre will be at I in the beginning of the eclipſe, and at K in the ending of it. Now, in the triangle PSI, there are given SI and SP to find PI=PK, which reduced to time, by help of the moon's apparent horary motion, gives half the duration of the eclipſe, and conſequently the beginning and end will be known.

VI. To find the quantity no, or the digits eclipſed, we have $no = Sn + Po - SP$, and $\frac{6no}{Po} =$ the number of digits.

N. B. The time found being mean time, muſt be reduced to the apparent time, by the equation of time. And if the given place be not that for which the tables are made, a proper allowance muſt be made for the difference of meridians.

PROPOSITION V. *To calculate the Time of the Moon's Southing.*

RULE. Subtract the ſun's right aſcenſion in time from the moon's right aſcenſion in time at noon on the day preceding the time when the moon's ſouthing is required, and the remainder will be the time preceding noon, of the moon's diſtance from the meridian, when the ſun at noon is upon it. Find the increaſe of the moon's right aſcenſion above the ſun's, in the ſpace of 24 hours. Then ſay as 24 hours is to the increaſe of the moon's right aſcenſion in time, ſo is the diſtance of the moon's from the ſun's right aſcenſion in time on the noon of the preceding day, to the proportional increaſe of the moon's right aſcenſion above that of the ſun's in time, to be added to the moon's diſtance from the meridian at noon, for the true time of the moon's ſouthing.

N. B. When the ſun's right aſcenſion is greater than the moon's, 24 hours muſt be added to the latter, that ſubtraction may be made of the firſt.

PROPOSITION VI. *To find the Time of the Moon's riſing and ſetting.*

I. For the eſtimate time. RULE. Subtract the right aſcenſion of the ſun from the oblique aſcenſion of the moon, in time, to which add or ſubtract 6 hours, according as the remainder is leſs or greater than 6 hours. From new to full moon, it is the ſetting that is to be found, but from full to new moon, the riſing muſt be found.

For the true time. Take the ſun's oblique aſcenſion in time, (according to the given latitude) at the eſtimate time of the moon's riſing, from the moon's oblique aſcenſion at the ſame time; and add the time of ſun-riſe to the remainder, for the near time of the moon's riſing that day. And to correct the time ſtill nearer, repeat the operation by computing the oblique aſcenſions for the time laſt found.

In like manner, the time of the moon's ſetting is found by taking the oblique aſcenſion of the ſun from the oblique aſcenſion of the moon, at the eſtimate time of ſetting; and by adding the time of the ſun's ſetting on that day, to the remainder, which may be corrected as the former.

SECT. XV.

DR. HERSCHEL's DESCRIPTION OF THE UNIVERSE.

IT was the opinion of former aſtronomers, that our ſun, beſides occupying the centre of the ſyſtem which properly belongs to him, occupied alſo the centre of the univerſe; but Dr. Herſchel is of a very different opinion.

With a Newtonian reflector of 20 feet focal length, and an aperture of 18 inches, he firſt began to ſurvey the Via Lactea, and found that it completely reſolved the whitiſh appearance into ſtars, which the teleſcopes he formerly uſed had not light enough to do. The portion he firſt obſerved was that about the hand and club of Orion, and found therein an aſtoniſhing multitude of ſtars, whoſe number he endeavoured to eſtimate by dividing them into what he calls fields of ſtars, and counting their number, and ſo computing from a mean of theſe, how many might be contained in a given portion of the milky-way. In the moſt vacant place to be met with in that neighbourhood he found 63 ſtars; other ſix fields contained 110, 60, 70, 90, 70, and 74 ſtars; a mean of all which gave 79 for the number of ſtars to each field: and thus he found, that by allowing 15 minutes for the diameter of his field of view, a belt of 15 degrees long and two broad, which he had often ſeen paſs before his teleſcope in an hour's time, could not contain leſs than 50,000 ſtars, large enough to be diſtinctly numbered; beſides which, he ſuſpected twice as many more, which could be ſeen only now and then by faint glimpſes for want of ſufficient light.

The ſucceſs he had with the milky-way ſoon induced him to turn his teleſcope to the nebulous parts of the heavens. Moſt of theſe yielded to his reflector, which plainly diſcovered them to be compoſed of ſtars, or at leaſt to contain ſtars, and to ſhow every other indication of conſiſting of them entirely. "The nebulæ, ſays Dr. Herſchel, are arranged into ſtrata, and run on to a great length; and ſome of them I have been able to purſue, and to gueſs pretty well at their form and direction. It is probable enough that they may ſurround the whole ſtarry ſphere of the heavens, not unlike the milky-way, which undoubtedly is nothing but a ſtratum of fixed ſtars: one of theſe nebulous beds, is ſo rich, that, in paſſing through a ſection of it in the time of only 36 minutes, I have detected no leſs than 31 nebulæ, all diſtinctly viſible upon a fine blue ſky. Their ſituation and ſhape, as well as condition, ſeem to denote the greateſt variety imaginable. In another ſtratum, or perhaps a different branch of the former, I have often ſeen double and treble nebulæ variouſly arranged; large ones with ſmall, ſeeming attendants; narrow, but much extended lucid nebulæ or bright daſhes; ſome of the ſhape of a fan, reſembling an electric bruſh iſſuing from a lucid point; others of the cometic ſhape, with a ſeeming nucleus in the centre, or like cloudy ſtars, ſurrounded with a nebulous atmoſphere: a different ſort again contain a nebuloſity of the milky kind, while others ſhine with a fainter mottled kind of light, which denotes their being reſolvable into ſtars.

"It is very probable that the great ſtratum called the *milky-way*, is that in which the ſun is placed, though perhaps not in the very centre of its thickneſs. We gather this from the appearance of the galaxy, which ſeems to encompaſs the whole heavens, as it certainly muſt do if the ſun is within the ſame.

"Thus in *Figure* 32. an eye at S within the ſtratum *a b*, will ſee the ſtars in the direction of its length *ab*, or height *e d*, with all thoſe in the intermediate ſituation, projected into the lucid circle ABCD; while thoſe in the ſides *me*, *nw*, will be ſeen ſcattered over the remaining part of the heavens at MVNW.

"If the eye were placed ſomewhere without the ſtratum, at no very great diſtance, the appearance of the ſtars within it would aſſume the form of one of the leſſer circles of the ſphere, which would be more or leſs contracted to the diſtance of the eye; and if this diſtance were exceedingly increaſed, the whole ſtratum might at laſt be drawn together into a lucid ſpot of any ſhape, according to the poſition, length, and height of the ſtratum.

"Let us now ſuppoſe, that a branch or ſmaller ſtratum ſhould run out from the former in a certain direction, and let it alſo be be contained between two parallel planes extended indefinitely onwards, but ſo that the eye may be placed in the great ſtratum ſomewhere before the ſeparation, and not far from the place where the ſtrata are ſtill united; then will this ſecond ſtratum not be projected into a bright circle like the former, but will be ſeen as a lucid branch proceeding from the firſt, and returning to it again at a certain diſtance leſs than a ſemicircle. Thus, in the ſame figure, the ſtars in the ſmall ſtratum *pg* will be projected into a bright arc at PRRP, which, after its ſeparation from the circle CBD, unites with it again at P.

"What has been inſtanced in parallel planes may eaſily be applied to ſtrata irregularly bounded, and running in various directions; for their projection will of conſequence vary according to the quantities of the variations in the ſtrata and the diſtance of the eye from the ſame. And thus any kind of curvatures, as well as various degrees of brightneſs, may be produced in the projections.

"From appearances, then, we may infer, that the ſun is moſt likely placed in one of the great ſtrata of the fixed ſtars, and very probably not far from the place where ſome ſmaller ſtratum branches out from it.

"Various methods may be taken to come to a knowledge of the ſun's place in the ſidereal ſtratum, one of which I have already begun to put in practice. I call it *gauging the heavens*, or the *ſtar-gauge*. It conſiſts in repeatedly taking the number of ſtars in ten fields of view of my reflector very near each other; and by adding their ſums, and cutting off one decimal on the right, a mean of the contents of the heavens in all the parts which are thus gauged are obtained. Thus it appears, that the number of ſtars increaſes very much as we approach the milky way; for in the parallel from 92 to 94 degrees north polar diſtance, and right aſcenſion 15 h. 10′, the ſtar-gauge runs up from 9.4 ſtars in the field to 18.6 in about an hour and an half; whereas in the parallel from 78 to 80 degrees north polar diſtance, and R. A. 11, 12, 13, and 14 hours, it very ſeldom riſes above 4. We are, however, to remember, that, with different inſtruments, the account of the gauges will be very different, eſpecially on our ſuppoſition of the ſun in a ſtratum of ſtars. For let *ab*, Plate IV. *Figure* 33. be the ſtratum, and ſuppoſe the ſmall circle *ghlk* to repreſent the ſpace into which, by the light and power of a given teleſcope, we are enabled to penetrate, and let GHLK be the extent of another portion which we are enabled to viſit by means of a larger aperture and power; it is evident, that the gauges with the latter inſtrument will differ very much in their account of ſtars contained at MN and at KG or LH, when with the former they will hardly be affected with the change from *mn* to *kg* or *lk*.

"The ſituation of the ſun in the ſidereal ſtratum will be found by conſidering in what manner the ſtar-gauge agrees with the length of a ray revolving in ſeveral directions about an aſſumed point, and cut off by the bounds of the ſtratum. Thus, in *Figure* 34. let S be the place of an obſerver; S rrr, *Srrr*, lines in the plane rSr, *rSr*, drawn from S within the ſtratum to one of the boundaries here repreſented by the plane AB. Then, ſince neither the ſituation of S nor the form of the limiting ſurface AB, is known, we are to aſſume a point, and apply to it lines proportional to the ſeveral gauges that have been obtained, and at ſuch angles from each other as they may point out; then will the termination of theſe lines delineate the boundary of the ſtratum, and conſequently manifeſt the ſituation of the ſun within the ſame.

"In my late obſervations on nebulæ, I ſoon found, that I generally detected them in certain directions rather than in others: that the ſpaces preceding them were generally quite deprived of their ſtars, ſo as often to afford many fields without a ſingle ſtar in it: that the nebulæ generally appeared ſome time after among ſtars of a certain conſiderable ſize, and but ſeldom among very ſmall ſtars: that when I came to one nebula, I generally found ſeveral more in the neighbourhood: that afterwards a conſiderable time paſſed before I came to another parcel. Theſe events being often repeated in different altitudes of my inſtrument, and ſome of them at conſiderable diſtances from each other, it occurred to me that the intermediate ſpaces between the ſweeps might alſo contain nebulæ; and finding this to hold good more than once, I ventured to give notice to my aſſiſtant at the clock, that 'I found myſelf on nebulous ground.' But how far theſe circumſtances of vacant places preceding and following the nebulous ſtrata, and their being as it were contained in a bed of ſtars ſparingly ſcattered between them, may hold good in more diſtant portions of the heavens, and which I have not yet been able to viſit in any regular manner, I ought by no means to hazard a conjecture."

By a continued ſeries of obſervations, Dr. Herſchel became confirmed in his judgment; and in a ſucceeding paper has given a ſketch of his opinions concerning the interior conſtruction of the heavens. "That the milky way, ſays he, is a moſt extenſive ſtratum of ſtars of various ſizes, admits no longer of the leaſt doubt; and that our ſun is one of the heavenly bodies belonging to it, is as evident. I have now viewed and gauged this ſhining zone in almoſt every direction, and find it compoſed of ſhining ſtars, whoſe number, by the account of thoſe gauges, conſtantly increaſes and decreaſes in proportion to its apparent brightneſs to the naked eye. But in order to develope the ideas of the univerſe that have been ſuggeſted by my late obſervations, it will be beſt to take the ſubject from point of view at a conſiderable diſtance both of ſpace and time.

"Let us then ſuppoſe numberleſs ſtars of various ſizes ſcattered over an indefinite portion of ſpace, in ſuch a manner as to be almoſt equally diſtributed through the whole. The laws of attraction, which no doubt extend to the remoteſt regions of the fixed ſtars, will operate in ſuch a manner as moſt probably to produce the following remarkable effects.

"I. It will frequently happen, that a ſtar, being conſiderably larger than its neighbouring ones, will attract them more than they will be attracted by others that are immediately around them; by which means they will be in time, as it were, condenſed about a centre; or, in other words, form themſelves into a cluſter of ſtars of almoſt a globular figure, more or leſs regularly ſo according to the ſize and original diſtance of the ſurrounding ſtars.

"II. The next caſe, which will happen almoſt as frequently as the former, is where a few ſtars, though not ſuperior in ſize to the reſt, may chance to be rather nearer each other than the ſurrounding ones; for here alſo will be formed a prevailing attraction in the combined centre of gravity of them all, which will occaſion the neighbouring ſtars to draw together; not, indeed, ſo as to form a regular globular figure, but, however, in ſuch a manner as to be condenſed towards the common centre of gravity of the whole irregular cluſter. And this conſtruction admits of the utmoſt variety of ſhapes, according to the number and ſituation of the ſtars which firſt gave riſe to the condenſation of the reſt.

"III. From the compoſition and repeated conjunction of both the foregoing forms, a third may be derived, when many large ſtars, or combined ſmall ones, are ſituated in long extended regular or crooked rows, hooks, or branches; for they will alſo draw the ſurrounding ones ſo as to produce figures of condenſed ſtars coarſely ſimilar to the former, which gave riſe to theſe condenſations.

"IV. Likewiſe, when a cluſter of ſtars is forming in one part of a ſpace, there may be another collecting in a different, but perhaps not far diſtant, quarter, which may occaſion a mutual approach towards their common centre of gravity.

"V. In the laſt place, as a natural conſequence of the former caſes, there will be great cavities or vacancies formed by the retreat of the ſtars towards the various centres which attract them; ſo that, upon the whole, there is evidently a field of the greateſt variety for the mutual and combined attractions of the heavenly bodies to exert themſelves in.

"From this theoretical view of the heavens, which has been taken from a point not leſs diſtant in time than in ſpace, we will now retreat to our own retired ſtation, in one of the planet's attending a ſtar in its great combination with numberleſs others: and in order to inveſtigate what will be the appearances from this contracted ſituation, let us begin with the naked eye. The ſtars of the firſt magnitude, being in all probability the neareſt, will furniſh us with a ſtep to begin our ſcale. Setting off, therefore, with the diſtance of Sirius or Arcturus, for inſtance, as unity, we will at preſent ſuppoſe, that thoſe of the ſecond magnitude are at double, thoſe of the third at treble, the diſtance, &c. Taking it for granted then, that a ſtar of the ſeventh magnitude (the ſmalleſt ſuppoſed viſible with the naked eye) is about ſeven times as far as one of the firſt, it follows, that an obſerver who is incloſed in a globular cluſter of ſtars, and not far from the centre, will never be able with the naked eye to ſee to the end of it; for ſince, according to the above eſtimations, he can only extend his view to about ſeven times the diſtance of Sirius, it cannot be expected that his eyes ſhould reach the borders of a cluſter which has perhaps not leſs than 50 ſtars in depth every were around him. The whole univerſe to him, therefore, will be compriſed in a ſet of conſtellations richly ornamented with ſcattered ſtars of all ſizes. Or if the united brightneſs of a neighbouring cluſter of ſtars ſhould, in a remarkable clear night, reach his ſight, it will put on the appearance of a ſmall, faint, whitiſh, nebulous cloud, not to be perceived without the greateſt attention. Let us ſuppoſe him placed in a much extended ſtratum, or branching cluſter of millions of ſtars, ſuch as may fall under the third form of nebulæ already conſidered. Here alſo the heavens will not only be richly ſcattered over with brilliant conſtellations, but a ſhining zone or milky way will be perceived to ſurround the whole ſphere of the heavens, owing to the combined light of thoſe ſtars which are too ſmall, that is, too remote to be ſeen. Our obſerver's ſight will be ſo confined, that he will imagine this ſingle collection of ſtars, though he does not even perceive the thouſandth part of them, to be the whole contents of the heavens. But allowing him now the uſe of a common teleſcope, he begins to perceive that all the milkineſs of the bright path which ſurrounds the ſphere is effected by ſtars. He perceives, that thoſe objects which had been called nebulæ, are evidently nothing but cluſters of ſtars. Their number encreaſes upon him; and when he reſolves one nebula into ſtars, he diſcovers ten new ones which he cannot reſolve. He then forms the idea of immenſe ſtrata of fixed ſtars, of cluſters of ſtars and of nebulæ; till, going on with ſuch interreſting obſervations, he ſtill perceives, that all theſe appearances muſt naturally ariſe from the confined ſituation in which he is placed.

Dr. Herſchel then propoſes the following

PROBLEM.

"The ſtars being ſuppoſed nearly equally ſcattered, and their number, in a field of view of a known angular diameter, being given, to determine the length of the viſual ray.

"Here, the arrangement of the ſtars not being fixed upon, we muſt endeavour to find which way they may be placed ſo as to fill a given ſpace moſt equally. Suppoſe a rectangular cone cut into fruſtula by many equidiſtant planes perpendicular to the axis; then, if one ſtar be placed at the vertex and another in the axis at the firſt interſection, ſix ſtars may be ſet around it ſo as to be equally diſtant from one another, and from the central ſtar. Theſe poſitions being carried on in the ſame manner, we ſhall have every ſtar within the cone ſurrounded by eight others at an equal diſtance from that ſtar taken as a centre. *Figure* 35 contains four ſections of ſuch a cone diſtinguiſhed by alternate ſhades; which will be ſufficient to explain what ſort of arrangement I would point out.

"The ſeries of the number of ſtars contained in the ſeveral ſections will be 1, 7, 19, 37, 61, 91, &c. which, continued to n terms, the ſum of it, by the differential method, will be $na + n.\frac{n-1}{2}d' + n.\frac{n-1}{2}.\frac{n-2}{3}d''$, &c. where a is the firſt term, d', d'', d''', &c. the firſt, ſecond, and third differences. Then, ſince $a=1$, $d'=6$, $d''=6$, $d'''=0$, the ſum of the ſeries will be n^3. Let S be the given number of ſtars; 1 the diameter of the baſe of the field of view; and B the diameter of the great rectangular cone; then by trigonometry we ſhall have $B = \frac{\text{Radius}}{\text{Tang. } \frac{1}{2}\text{ field}}$. Now, ſince the field of view of a teleſcope is a cone, we ſhall have its ſolidity to that of the great cone of the ſtars formed by the above conſtruction, as the ſquare of the diameter of the baſe of the field of view to the ſquare of the diameter of the great cone, the height of both being the ſame; and the ſtars in each cone being in the ratio of the ſolidity, as being equally ſcattered, we have $n = \sqrt[3]{B^2 S}$; and the length of the viſual ray $= n - 1$, which was to be determined." Another ſolution of this problem, on the ſuppoſition of another arrangement of ſtars, is given; but Dr. Herſchel prefers the former.

From the data now laid down, Dr. Herſchel next endeavours to prove that the earth is 'the planet of a ſtar belonging to a compound nebula of the third form.' "I ſhall now, (ſays he) proceed to ſhow, that the ſtupendous ſidereal ſyſtem we inhabit, this extenſive ſtratum, and its ſecondary branch, conſiſting of many millions of ſtars, is in all probability a detached nebula. In order to go upon grounds that ſeem to me to be capable of great certainty, they being no leſs than an actual ſurvey of the boundaries of our ſidereal ſyſtem, which I have plainly perceived as far as I have yet gone round it, every where terminated, and in moſt places very narrowly too, it will be proper to ſhow the length of my ſounding line, if I may ſo call it, that it may appear whether it was ſufficiently long for the purpoſe.

"In the moſt crowded parts of the milky-way, I have had fields of view that contained no fewer than 588 ſtars, and theſe were continued for many minutes; ſo that in one quarter of an hour's time there paſſed no leſs than 116,000 ſtars through the field of view of my teleſcope. Now if we compute the length of the viſual ray, by putting $S = 588$, and the diameter of the field of view 15 minutes, we ſhall find $n = \sqrt{B^2 S} = 498$; ſo that it appears the length of what I have called my ſounding line, or $n - 1$, was not probably leſs than 497 times the diſtance of Sirius from the ſun.

"It may ſeem inaccurate that we ſhould found an argument on the ſtars being equally ſcattered, when, in all probability, there may not be any two of them in the heavens whoſe mutual diſtance ſhall be equal to that of any other two given ſtars: but it ſhould be conſidered, that when we take all the ſtars collectively, there will be a mean diſtance which may be aſſumed as the general one; and an argument founded on ſuch a ſuppoſition will have in its favour the greateſt probability of not being far ſhort of truth.

"If ſome other high gauge be ſelected from the table, ſuch as 472 or 344, the length of the viſual ray will be found 461 and 415. And although in conſequence of what has been ſaid, a certain degree of doubt may be left about the arrangement and ſcattering of the ſtars, yet when it is recollected, that in thoſe parts of the milky-way, where theſe high gauges were taken, the ſtars were neither ſo ſmall nor ſo crowded, as they muſt have been, on a ſuppoſition of a much farther continuance of them, when certainly a milky or nebulous appearance muſt have come on, I need not fear to have over-rated the extent of my viſual ray; and indeed every thing that can be ſaid to ſhorten it will only contract the limits of our nebulæ, as it has in moſt places been of ſufficient length to go far beyond the bounds of it. Thus in the ſides of our ſtratum, oppoſite to our ſituation in it, where the gauges often run below 5, our nebulæ cannot extend to 100 times the diſtance of Sirius; and the ſame teleſcope which could ſhow 588 ſtars in a field of view of 15 minutes, muſt certainly have preſented me alſo with the ſtars in theſe ſituations, had they been there. If we ſhould anſwer this by obſerving, that they might be at too great a diſtance to be perceived, it will be allowing that there muſt at leaſt be a vacancy amounting to the length of a viſual ray, not ſhort of 400 times the diſtance of Sirius; and this is amply ſufficient to make our nebulæ a detached one. It is true, that it would not be conſiſtent confidently to affirm that we were on an iſland, unleſs we had found ourſelves every where bounded by the ocean; and therefore I ſhall go no farther than the gauges will authoriſe: but conſidering the little depth of the ſtratum in all thoſe places which have been actually gauged, to which muſt be added all the intermediate parts that have been viewed and found to be much like the reſt, there is but little room to expect a connection between our nebula and any of the neighbouring ones. A teleſcope, with a much larger aperture than my preſent one, graſping together a greater quantity of light, and thereby enabling us to ſee farther into ſpace, will be the ſureſt means of completing and eſtabliſhing the arguments that have been uſed: for if our nebula is not abſolutely a detached one, I am firmly perſuaded that an inſtrument may be made large enough to diſcover the places where the ſtars continue onwards. A very bright milky nebuloſity muſt there undoubtedly come on, ſince the ſtars in a field of view will increaſe in the ratio of n^3 greater than that of the cube of the viſual ray.

Thus, if 588 ſtars, in a given field of view, are to be ſeen by a ray of 497 times the diſtance of Sirius, when this is lengthened to 1000, which is but little more than double the former, the number of ſtars in the ſame field of view will be no leſs than 4774: for when the viſual ray r is given, the number of ſtars S, will be $= \frac{n^3}{B^2}$; where $n = r + 1$; and a teleſcope with a threefold power of extending into ſpace, or with a ray of 1500, which I think may eaſily be conſtructed, will give us 16096 ſtars. Nor would theſe be ſo cloſe, but that a good power applied to ſuch an inſtrument might eaſily diſtinguiſh them; for they need not, if arranged in regular ſquares, approach nearer to each other than 6''.27: but the milky nebuloſity I have mentioned, would be produced by the numberleſs ſtars beyond them, which, in one reſpect, the viſual ray might alſo be ſaid to reach. To make this appear, we muſt return to the naked eye; which, as we have before eſtimated, can only ſee the ſtars of the ſeventh magnitude, ſo as to diſtinguiſh them: but it is nevertheleſs very evident, that the united luſtre of millions of ſtars, ſuch as I ſuppoſe the nebula in Andromeda to be, will reach our ſight in the ſhape of a very ſmall faint nebuloſity; ſince the nebula of which I ſpeak may eaſily be ſeen in a fine evening. In the ſame manner my preſent teleſcope, as I have argued, has not only a viſual ray that will reach the ſtars at 497 times the diſtance of Sirius, ſo as to diſtinguiſh them, and probably much farther, but alſo a power of ſhowing the united luſtre of the accumulated ſtars that compoſe a milky nebuloſity at a diſtance far exceeding the former limits: ſo that from theſe conſiderations it appears again highly probable, that my preſent teleſcope, not ſhewing ſuch a nebuloſity in the milky-way, goes already far beyond its extent; and conſequently much more would an inſtrument, ſuch as I have mentioned, remove all doubt on the ſubject, both by ſhowing the ſtars in the continuation of the ſtratum, and by expoſing a very ſtrong milky nebuloſity beyond them, that could no longer be miſtaken for the dark ground of the heavens.

Dr. Herſchel offers ſome thoughts on the origin of the nebulous ſtrata of the heavens and their antiquity. "If it were poſſible, ſays he, to diſtinguiſh between the parts of an indefinitely extended whole, the nebula we inhabit might be ſaid to be one that has fewer marks of antiquity than any of the reſt. To explain this idea perhaps more clearly, we ſhould recollect, that the condenſation of cluſters of ſtars has been aſcribed to a gradual approach; and whoever reflects on the number of ages that muſt have paſſed before ſome of the cluſters that are to be found in my intended catalogue of them could be ſo far condenſed as we find them at preſent, will not wonder if I aſcribe a certain air of youth and vigour to many very regularly ſcattered regions of our ſidereal ſtratum. There are, moreover, many places in it, in which, if we may judge from appearances, there is the greateſt reaſon to believe, that the ſtars are drawing towards ſecondary centres, and will in time ſeparate into cluſters, ſo as to occaſion many ſubdiviſions. Hence we may ſurmiſe, that when a nebulous ſtratum conſiſts chiefly of nebulæ of the firſt and ſecond forms, it probably owes its origin to what may be called the decay of a great compound nebula of the third form; and that the ſubdiviſions which happened to it in length of time, occaſioned all the ſmall nebulæ which ſprung from it to lie in a certain range, according as they were detached from the primary one. In like manner, our ſyſtem, after numbers of ages, may very poſſibly become divided ſo as to give riſe to a ſtratum of two or three hundred nebulæ; for it would not be difficult to point out ſo many beginning or gathering cluſters in it.

"Some parts of our ſyſtem ſeem already to have ſuſtained greater ravages of time than others: for inſtance, in the body of the Scorpion is an opening or hole, which is probably owing to this cauſe. It is at leaſt four degrees broad; but its height I have not yet aſcertained."

Thus, then, according to Dr. Herſchel, the univerſe conſiſts of nebulæ, or innumerable collections of innumerable ſtars, each individual of which is a ſun not only equal, but much ſuperior to ours.

Though in the above extracts from Dr. Herſchel's papers, the words *condenſation*, *cluſters*, &c. of ſtars, frequently occur, we are by no means from thence to imagine that any of the celeſtial bodies in our nebulæ are nearer to one another than we are to Sirius, whoſe diſtance is ſuppoſed not to be leſs than 400,000 times that of the ſun from us, or 38 millions of millions of miles. The whole extent of the nebula being in ſome places near 500 times as great, muſt be ſuch, that the light of a ſtar placed at its extreme boundary, ſuppoſing it to fly with the velocity of 12 millions of miles every minute, muſt have taken near 3000 years to reach us. Dr. Herſchel, however, is by no means of opinion, that our nebula is the moſt conſiderable in the univerſe.

"My opinion, ſays the doctor, of their ſize is grounded on the following obſervations: There are many round nebulæ of the firſt form, of about five or ſix minutes in diameter, the ſtars of which I can ſee very diſtinctly; and on comparing them with the viſual ray calculated from ſome of my long gauges, I ſuppoſe by the appearance of the ſmall ſtars in thoſe gauges, that the centres of theſe round nebulæ may be 600 times the diſtance of Sirius from us." He then goes on to tell us, that the ſtars in ſuch nebulæ are probably twice as much condenſed as thoſe of our ſyſtem; otherwiſe the centre of it would not be leſs than 6000 times the diſtance of Sirius from us; and that it is poſſibly much under-rated by ſuppoſing it only 600 times the diſtance of that ſtar.

In the courſe of Dr. Herſchel's obſervations and inquiries concerning the ſtructure of the heavens, an objection occurred, that if the different ſyſtems were formed by the mutual attractions of the ſtars, the whole would be in danger of deſtruction by the falling of them one upon another. A ſufficient anſwer to this, he thinks, is, that if we can really prove the ſyſtem of the univerſe to be what he has ſaid, there is no doubt but that the great author of it has amply provided for the preſervation of the whole, though it ſhould not appear to us in what manner this is effected. Several circumſtances, however, he is of opinion, manifeſtly tend to a general preſervation; as, in the firſt place, the indefinite extent of the ſidereal heavens, which muſt produce a balance that will effectually ſecure all the great parts of the whole from approaching to each other. "There remains then, ſays he, only to ſee how the particular ſtars belonging to ſeparate cluſters are prevented from ruſhing on to their centres of attraction." This he ſuppoſes may be done by projectile forces; "the admiſſion of which will prove ſuch a barrier againſt the ſeeming deſtructive power of attraction, as to ſecure from it all the ſtars belonging to a cluſter, if not for ever, at leaſt for millions of ages. Beſides, we ought perhaps to look upon ſuch cluſters, and the deſtruction of a ſtar now and then in ſome thouſand of ages, as the very means by which the whole is preſerved and renewed. Theſe cluſters may be the laboratories of the univerſe, wherein the moſt ſalutary remedies for the decay of the whole are prepared.

SECT. XVI.

PLATE I. FIGURE I.

OF ASTRONOMICAL INSTRUMENTS.

DESCRIPTION OF THE UNIVERSAL EQUATORIAL,

As conſtructed by Mr. George Adams, *of Fleet Street.*

THE principal parts of this inſtrument are the azimuth, or horizontal circle YZ, *a* the nut to turn it. LM, the hour circle; ABD, the teleſcope; and *de*, its level; C, a ſcrew for adjuſting the hairs; the declination circle EKG, and its pinion F; the nonius to this circle is marked H; IK the axis for the teleſcope; *c* a ſmall level to this axis. O is the nut by which the hour circle is turned round; R, S, T, the adjuſting ſcrews that ſupport the inſtrument; X the axis of the azimuth circle; V the nonius thereto, and W, W, two ſpirit levels; PYQ the latitude arch.

The reader will obtain a perfect idea of the various uſes to which this inſtrument may be applied by the following Problems.

Problem I. *To take the Meridian Altitude of the Sun, Moon, or Star, &c.*

Make the polar axis perpendicular to the horizon, and when the ſun is coming near to the meridian, elevate the teleſcope till the centre of the ſun is exactly in the centre of the croſs wires; then follow the ſun, by moving both the equatoreal and declination circles, if neceſſary, till he is at his greateſt altitude; the nonius of the declination circle will then give you his meridian altitude.

Problem II. *To find the Meridian by one Obſervation only.*

To do this, elevate the equatoreal (or hour) circle to the co-latitude of the place, and ſet the declination circle to the ſun's declination for the day and hour of the day required; then move the azimuth and hour circles, both at the ſame time, either in the ſame direction, or the contrary, till you bring the centre of the croſs wires in the teleſcope exactly to cover the centre of the ſun: that being done, the index of the hour will give the apparent, or ſolar time at the inſtant of obſervation. Thus you get the time, though the ſun be at a diſtance from the meridian; then turn the hour circle till the index points preciſely at 12 o'clock, and lower the teleſcope to the horizon in order to obſerve ſome point there, in the centre of your glaſs, and that point is your meridian mark found by one obſervation only. The beſt time of the day for this operation of finding your meridian, is three or four hours before, or three or four hours after twelve at noon.

Problem III. *To obſerve a Star or Planet in Broad Day-light, at any Time when it is above the Horizon.*

N. B. The table of right aſcenſions, declinations, &c. of the principal fixed ſtars, gives you the times of their tranſits over the meridian.

Elevate the equatoreal circle to the co-latitude of the place, and ſet the nonius of the declination circle to the ſtar's declination; look into the table for the time of its tranſit immediately preceding your obſervation; then take the interval of time ſince that tranſit to the time of your obſervation as given by the clock, and and add to it the ſtar's acceleration, correſponding to that interval of time, this ſum is the hour to which you muſt ſet the hour index of the equatoreal circle, and the ſtar will then appear in the teleſcope.

Problem IV. *To find the Right Aſcenſion, and Declination of a fixed Star, Planet, Comet, or the Moon, by an Obſervation made with the Equatoreal.*

The equatoreal circle being elevated as before to the complement of the latitude of the place, move the declination and equatoreal circulations, till the moon, ſtar, or comet, is in the centre of the croſs wires in the teleſcope; the nonius of the declination circle, will give you the hour of the ſtar, &c. then your regulator or clock will give you the ſun's time, or hour of the day. Take the difference between the ſun's time, and the ſtar's time; and if the ſtar's time is leſs than the ſun's time, add that difference, to the ſun's right aſcenſion at the time of obſervation, the ſum (rejecting 24 hours, if it exceeds that number) is the right aſcenſion of the ſtar, &c. Again, if the ſtar's time exceeds the ſun's time, ſubtract the difference from the ſun's right aſcenſion; the remainder (adding 24 hours, to the ſun's right aſcenſion, if neceſſary) is the right aſcenſion of the ſtar, &c.

Problem V. *To find the Longitude at Land.*

Obſerve the difference of the right aſcenſion of two celeſtial bodies; for inſtance, of the moon, and a known fixed ſtar; at any given time, either on, or out of the meridian, and from that difference, infer the moon's right aſcenſion, at the moment of obſervation; that being obtained, find what is the preciſe time, at any place whoſe longitude is well aſcertained; for inſtance, at Greenwich, when the moon has that right aſcenſion, which you have now obſerved; the difference between that time at Greenwich, and the time with you, is the difference of longitude, in time, between Greenwich, and your place of obſervation, which is Eaſt of Greenwich, if the time with you be later than the time at Greenwich, and is Weſt of Greenwich, if the time with you be earlier than that of Greenwich.

OF THE PLANETARIUM, TELLURIAN, AND LUNARIUM.

The Planetarium (Plate II. *Figure* 1.) is an inſtrument made by Mr. Adams of Fleet Street, London, who has paid conſiderable attention to thoſe ſort of machines, in order to reduce them to their greateſt degree of ſimplicity and perfection. It repreſents in a general manner, by various parts of its machinery, all the motions and phænomena of the planetary ſyſtem. This machine conſiſts of, the Sun (in the centre), with the planets, Mercury, Venus, the Earth and Moon, Mars, Jupiter and his four moons, Saturn and his five moons; and to it is occaſionally applied an extra long arm for the Georgian planet and his two moons. To the earth and moon is applied a frame, containing only four wheels and two pinions, which ſerve to preſerve the earth's axis in its proper paralleliſm in its motion round the ſun, and to give the moon her due revolution about the earth at the ſame time. Theſe wheels are connected with the wheel work in a round box below, and the whole is ſet in motion by a winch. The arm that carries round the moon, points out her age and phaſes for any ſituation in her orbit, as alſo her geocentric place in

TAURUS

Published according to Act of Parliament by C. Cooke No. 17 Paternoster Row, Oct. 10. 1788.

in the ecliptic, in ſigns and degrees. The moon's orbit is repreſented by a flat rim; the two joints upon which it turns, denoting her nodes. This orbit is made to incline to any deſired angle. The earth of this inſtrument is uſually made of a three-inch or 1½ globe, papered, &c. for the purpoſe; and by means of the terminating wire that goes over it, points out the changes of the ſeaſons, and the different lengths of days and nights more conſpicuouſly. This machine is alſo made to repreſent the Ptolemaic Syſtem, or ſuch as is vulgarly received; which places the earth in the centre, and the planets and ſun revolving about it. (It is done by an auxiliary ſmall ſun and an earth, which change their places in the inſtrument.) At the ſame time, it affords a moſt manifeſt confutation of it: for it is plainly obſerved in this conſtruction, (1.) That the planets Mercury and Venus, being both within the orbit of the ſun, cannot at any time be ſeen to go behind it; whereas in nature we obſerved them as often to go behind as before the ſun in the heavens. (2.) It ſhows, that as the planets move in circular orbits about the central earth, they ought at all times to be of the ſame apparent magnitude; whereas, on the contrary, we obſerve their apparent magnitude in the heavens to be very variable, and ſo far different, that, for inſtance, Mars will ſometimes appear as big as Jupiter nearly, and at other times you will ſcarcely know him from a fixed ſtar. (3.) It ſhows that any of the planets might be ſeen at all diſtances from the ſun in the heavens; or, in other words, that when the ſun is ſetting, Mercury or Venus may be ſeen not only in the ſouth but even in the eaſt; which circumſtances were never yet obſerved. (4.) You ſee by this planetarium that the motions of the planets ſhould always be regular and uniformly the ſame; whereas, on the contrary, we obſerve them always to move with a variable velocity, ſometimes faſter, then ſlower, and ſometimes not at all. (5.) By the machine you ſee the planets move all the ſame way, viz. from weſt to eaſt continually: but in the heavens we ſee them move ſometimes direct from weſt to eaſt, ſometimes retrograde from eaſt to weſt, and at other times to be ſtationary. All which phænomena plainly prove this ſyſtem to be a falſe and abſurd hypotheſis.

The truth of the Copernican or Solar Syſtem of the world is hereby moſt clearly repreſented. For taking the earth from the centre, and placing thereon the uſual large braſs ball for the ſun, and reſtoring the earth to its proper ſituation among the planets, then every thing will be right and agree exactly with celeſtial obſervations. You will obſerve Mercury never to be more than a certain angular diſtance, 21°, and Venus 47°, from the ſun. That the planets, eſpecially Mars, will be ſometimes much nearer to the earth than at others, and therefore muſt appear larger at one time than at another. And that they cannot appear at the earth to move with an uniform velocity; for when neareſt they appear to move faſteſt, and ſlower when moſt remote. You will alſo obſerve their motions to be ſometimes direct, and ſometimes retrograde, when after a time they become ſtationary. Which particulars all correſpond exactly with obſervations, and fully prove the truth of this excellent ſyſtem.

Wherefore by this machine you at once ſee all the planets in motion about the ſun, with the ſame reſpective velocities and periods of revolution which they have in the heavens; the wheel-work being calculated to a minute of time, from the lateſt diſcoveries.

The diurnal rotation of the earth about its axis, the different ſeaſons of the year, and the different lengths of days and nights, are likewiſe here completely exhibited.

In ſhort by this inſtrument every phænomenon in nature is repreſented as it actually appears in the heavens.

ROWLEY's GRAND ORRERY.

The machine repreſented by (Plate II. *Figure* 2.) is the Grand Orrery, firſt made in this kingdom by Mr. Rowley for king George I. The frame of it, which contains the wheel-work, &c. and regulates the whole, is made of ebony, and about four feet in diameter; the outſide thereof is adorned with 12 pilaſters. Between theſe the 12 ſigns of the zodiac are neatly painted with gilded frames. Above the frame is a broad ring ſupported with 12 pillars. This ring repreſents the plane of the ecliptic; upon which are two circles of degrees, and between theſe the names and characters of the 12 ſigns. Near the outſide is a circle of months and days, exactly correſponding to the ſun's place at noon each day throughout the year. Above the ecliptic ſtand ſome of the principal circles of the ſphere, agreeable to their reſpective ſituations in the heavens: viz. N° 10. are the two colures, divided into degrees and half degrees, N° 11. is one half of the equinoctial circle, making an angle of 23½ degrees. The tropic of Cancer and the arctic circle are each fixed parallel at their proper diſtance from the equinoctial. On the northern half of the ecliptic is a braſs ſemicircle, moveable upon two points fixed in ♈ and ♎. This ſemicircle ſerves as a moveable horizon to be put to any degree of latitude upon the north part of the meridian, and the whole machine may be ſet to any latitude without diſturbing any of the internal motions, by two ſtrong hinges, (N° 13) fixed to the bottom frame upon which the inſtrument moves, and a ſtrong braſs arch, having holes at every degree, through which a ſtrong pin is put at every elevation. This arch and the two hinges ſupport the whole machine when it is lifted up according to any latitude; and the arch at other times lies conveniently under the bottom frame. When the machine is ſet to any latitude (which is eaſily done by two men, each taking hold of two handles conveniently fixed for the purpoſe), ſet the moveable horizon to the ſame degree upon the meridian, and hence you may form an idea of the reſpective altitude or depreſſion of the planets both primary and ſecondary. The ſun (N° 1.) ſtands in the middle of the whole ſyſtem upon a wire, making an angle with the ecliptic of about 82 degrees. Next the ſun is a ſmall ball (2.), repreſenting Mercury. Next to Mercury is Venus (3.), repreſented by a larger ball. The earth is repreſented (N° 4.) by an ivory ball, having ſome circles and a map ſketched upon it. The wire which ſupports the earth makes an angle with the ecliptic of 66½ degrees, the inclination of the earth's axis to the ecliptic. Near the bottom of the earth's axis is a dial plate (N° 9.), having an index pointing to the hours of the day as the earth turns round its axis. Round the earth is a ring ſupported by two ſmall pillars, repreſenting the orbit of the moon; and the diviſions upon it anſwer to the moon's latitude. The motion of this ring repreſents the motion of the moon's orbit according to that of the nodes. Within this ring is the moon (N° 5.), having a black cap or caſe, by which its motion repreſents the phaſes of the moon according to her age. Without the orbits of the earth and moon in Mars (N° 6.). The next in order to Mars is Jupiter and his four moons (N° 7.). Each of theſe moons is ſupported by a wire fixed in a ſocket which turns about the pillar ſupporting Jupiter. Theſe ſatellites may be turned by the hand to any poſition, and yet when the machine is put into motion they will all move in their proper times. The outermoſt of all is Saturn, his five moons, and his ring (N° 8.). Theſe moons are ſupported and contrived ſimilar to thoſe of Jupiter. The machine is put into motion by turning a ſmall winch (N° 14.); and the whole ſyſtem is alſo moved by this winch, and by pulling out and puſhing in a ſmall cylindrical pin above the handle. When it is puſhed in, all the planets, both primary and ſecondary, will move according to their reſpective periods by turning the handle. When it is drawn out, the motion of the ſatellites of Jupiter and Saturn will be ſtopped, while all the reſt move without interruption. There is alſo a braſs lamp having two convex glaſſes to be put in room of the ſun; and alſo a ſmaller earth and moon, made ſomewhat in proportion to their diſtance from each other, which may be put on at pleaſure. The lamp turns round at the ſame time with the earth, and the glaſſes of it caſt a ſtrong light upon her.

And when the ſmaller earth and moon are placed on, it will be eaſy to ſhow when either of them will be eclipſed. When this machine is intended to be uſed, the planets muſt be duly placed by means of an ephemeris, and you may place a ſmall black patch or bit of wafer upon the middle of the ſun.

Right againſt the firſt degree of ♈, you may alſo place patches upon Venus, Mars, and Jupiter, right againſt ſome noted point in the ecliptic. Put in the handle, and puſh in the pin which is above it. One turn of this handle anſwers to a revolution of the balls which repreſents the earth about its axis; and conſequently to 24 hours of time, as ſhewn by the hour-index (9.), which is marked and placed at the foot of the wire on which the ball of the earth is fixed. Again, when the index has moved the ſpace of ten hours, Jupiter makes one revolution round its axis, and ſo of the reſt. By theſe means the revolutions of the planets, and their motions round their own axes, will be repreſented to the eye. By obſerving the motions of the ſpots upon the ſurface of the ſun and of the planets in the heavens, their diurnal motions were firſt diſcovered, after the ſame manner as we in this machine obſerve the motions of their repreſentatives by that of the marks placed upon them.

ADAMS's SMALL QUADRANT.

PLATE V. FIGURE I.

This is a very ſimple and uſeful inſtrument of this kind. ABC is the quadrant mounted on an axis and pedeſtal: (by means of the axis, it may be immediately placed in any vertical poſition, and the pedeſtal being moveable in the axis of the circle EF, ſerves to place it in the direction of any azimuth, or towards any point of the compaſs.) The limb AB is divided into degrees and halves, numbered from A; and upon the radius BC are fixed two ſights, of which be is perforated with a ſmall hole, and is provided with a dark glaſs, to defend the eye from the ſun's light; and the other ſight C has a larger hole, furniſhed with croſs wires, and alſo a ſmaller, which is of uſe to take the ſun's altitude by the projection of the bright image of that luminary upon the oppoſite ſight. From the center C hangs a plumb line CP. The horizontal circle FE is divided into four quadrants of 90 degrees; and an arm E, connected with the pedeſtal, moves along the limb, and conſequently ſhews the poſition of the place of the quadrant, as will hereafter be more minutely explained. Laſtly, the ſcrews G,H,I, render it very eaſy to ſet the whole inſtrument ſteadily and accurately in its proper poſition, notwithſtanding any irregularity in the table or ſtand it may be placed upon.

The rationale of this inſtrument is very clear and obvious. It is uſed to meaſure the angular diſtance of any body, or appearance, either from the zenith or point immediately above our heads, or from the horizon or level. The plumb line CP, if continued upwards from C, would be directed to the zenith Z; and the line CL, ſuppoſed to be drawn from the centre of the quadrant to an object L, will form an angle LCZ, which is the zenith diſtance, and is equal to the angle BCP, formed between the oppoſite parts of the ſame lines. We ſee, therefore, that the degrees on the arc, comprehended on the limb of the quadrant, between the plumb line and the extremities next the eye, meaſure the angle of zenith diſtance.

Again, the line CK (forming a right angle with the perpendicular CZ) is level, or horizontal; the angle LCK muſt therefore be the altitude or elevation of L above the horizon: and this laſt angle muſt be equal to the angle meaſured between the plumb line and the end A fartheſt from the eye; becauſe both theſe are equal to the quantity which would be left, after taking the zenith diſtance from a right angle, or the whole quadrant.

FIGURE II.

BIRD's TWELVE INCH QUADRANT.

The Method of adopting this Quadrant.

For performing this, there are three principal parts to be adjuſted, 1. The pillar is to be ſet perpendicular to the horizon. 2. One ſide of the quadrant is to be ſet perpendicular. 3. The axis of the teleſcope, or line of ſight, is to be made parallel to the horizontal radius of the quadrant.

I. *To ſet the Pillar perpendicular.*

Set the braſs pedeſtal on a firm ſupport. Then hang the quadrant on the pillar, and by the ſpirit-level and ſcrews in the feet, the pillar may be ſet perpendicular in the following manner: Turn the quadrant till the upper ſide is parallel to two oppoſite feet, and with one hand unſcrew that ſcrew of the foot towards which the buble inclines, and, at the ſame time, with the other hand ſcrew in the oppoſite ſcrew, till the buble reſts equally between the two marks, or ſcratches, on the glaſs tube; then turn the quadrant, horizontally, half round; and if the buble does not reſt exactly between the ſcratches as before, by unſcrewing that ſcrew towards which the buble inclines, and at the ſame ſcrewing in the other, make the buble move over half the ſpace in the tube by which they differ, and remember toward which end it inclines. Then turn the quadrant one quarter round, till its upper ſide is parallel to the other two feet; and if the buble does not reſt in the ſame place, with reſpect to the ſcratches, as it did before, make it do ſo by the ſcrews in the feet; and then bring it equally between the ſcratches, by lowering that end of the tube toward which the buble ſtood, or raiſing the other end. For doing this, there are three ſcrews at each end of the tube. To lower one end, ſlacken the right and left, or puſhing ſcrews, and ſcrew in the middle ſcrew, till the buble reſts equally between the two ſcratches: then the pillar and level are right, or nearly ſo. To prove if they are exact, or to make them ſo, if they are not; begin the ſame proceſs over again, by firſt turning the quadrant half round, and if the buble reſts not equally between the ſcratches, move it half the difference by the ſcrews in the feet; and then quarter round, and adjuſting the level firſt ſo far by the ſcrews in the feet, and next by raiſing or lowering one end of the tube as before directed; till you get the buble to ſtand in the ſame part of the glaſs when the quadrant is turned half round and quarter round; and the pillar and level will then be right.

II. *To make one Side of the Quadrant perpendicular.*

This is done by making the plumb-line hang firſt over the fine point at the arrow-head, on the center plate; and next to cover the other fine point on the arch below.

It is made to hang over the upper point, by ſcrewing the elaſtic bit of braſs (over which the wire of the plummet goes) out, or in, by its upper ſcrew-nail. It is made to hang over the lower point, by the adjuſting ſcrew within the quadrant, which is turned by a round brotched braſs-button on its head.

The plummet ſhould be made to hang in a ſmall cup, or veſſel, filled with water, to make it more ſteady, and reſt ſooner; and if the veſſel is faſtened by an arm to the pillar of the pedeſtal, ſo as to move round along with the quadrant, it will be the more convenient.

The plumb-line ſhould be made to hang very near the plane of the quadrant, at the lower arrow, but not to touch it: which is done by preſſing with the hand the elaſtic bit of braſs before mentioned, a little backward or forward.

III. *To adjuſt the Teleſcope, or to make its Axis horizontal, when the Index is at 90 Degrees.*

Set the index to 90, keeping the plummet and level right: then direct the teleſcope to ſome diſtant object above a mile off, (but the farther the better) till you ſee a remarkable part of it exactly at the horizontal wire: then take off the quadrant from the pillar, by unſcrewing the two large iron-ſcrews; and invert the quadrant, by ſcrewing it on again with the arc uppermoſt: then ſcrew to the arc of the quadrant a crooked bit of braſs, with a notch in it, as near the arrow as you can, and hang the plummet over that bit of braſs, moving it on one ſide or the other, till the line covers the point on the arc; and if it does not then cover the point on the centre plate alſo, make it do ſo by the ſcrews in the feet: then look through the teleſcope; and if the horizontal wire cuts the ſame part of the object it did before inverſion, the teleſcope is right. If the object appears higher or lower, the wire in the teleſcope muſt be moved half the difference, by the two ſteel ſcrews near the eye end of the teleſcope: if the object appears higher than the horizontal wire, eaſe the lower ſcrew, and ſcrew in the upper one; if the object appears below, eaſe the upper ſcrew, and ſcrew in the lower one; till the horizontal wire cuts the diſtant object at half the difference it did before inverting it: then it is adjuſted for obſervation.

The wire in the teleſcope that is applied to the limb of the ſun, in taking its altitude, ought to be exactly horizontal when the plane of the quadrant is perpendicular. To find if it is ſo: adjuſt the quadrant by the level and plummet, as before directed; then point the teleſcope to ſome ſmall diſtinct object at a diſtance, as the top of a rock, a chimney-head, &c. and remark a particular part of it which the wire croſſes: turn the quadrant a little about gently, towards one ſide; and if all parts of the wire paſs over the ſame part of the object, the wire is truly horizontal. But if one end of the wire croſſes the object higher, or lower, than the other, preſs the two ſmall ſcrews that govern the wire between your finger and thumb, and at the ſame time turn them ſide wiſe, but in oppoſite directions, till, upon looking again, and turning the quadrant, you find all parts of the wire paſs over the ſame part of the object; then it is truly horizontal.

MURAL QUADRANT.

FIGURE III.

Repreſents the inſtrument as fixed to a wall. It is of copper, and of about 5 feet radius. The frame is formed of flat bars, and ſtrengthened by edge bars affixed underneath perpendicularly to them. The radii HB, HA, being divided each into four equal parts, ſerves to find out the points D and E, by which the quadrant is freely ſuſpended on its props or iron ſupports that are faſtened ſecurely in the wall.

One of the ſupports E is repreſented ſeparately in *e* on one ſide of the quadrant. It is moveable by means of a long ſlender rod EF or *ef*, which goes into a hollow ſcrew in order to reſtore the inſtrument to its ſituation when it is diſcovered to be a little deranged. In order to prevent the unſteadineſs of ſo great a machine, there ſhould be placed behind the limb four copper ears with double cocks, I, K, I, K. There are others along the radii HA, and HB. Each of theſe cocks contain two ſcrews, into which is faſtened the ears that are fixed behind the quadrant.

Over the wall or ſtone which ſupports the inſtrument, and at the ſame height as the centre, is placed horizontally the axis PO. This axis turns on two pivots P. On this axis is fixed at right angles another branch ON, loaded at its extremity with a weight N, capable of equipoiſing with its weight that of the teleſcope LM; whilſt the axis, by its extremity neareſt the quadrant, carries the wooden frame PRM, which is faſtened to the teleſcope in M.

The lower extremity (V) of the teleſcope is furniſhed with two ſmall wheels, which take the limb of the quadrant on its two ſides.

When the teleſcope is to be ſtopped at a certain poſition, the copper hand T is to be made uſe of. It is fixed by a ſetting ſcrew, which faſtens it to the limb. Then, in turning the regulating ſcrew, the teleſcope will be advanced; which is continued until the ſtar or other object, whoſe altitude is obſerving, be on the horizontal fine thread in the teleſcope. Then on the plate X, ſupporting the teleſcope, and carrying a vernier or nonius, will be ſeen the number of degrees and minutes, &c. that the angular height of the object obſerved is equal to.

FIGURE IV.

HADLEY's SEXTANT.

For a deſcription of which the reader is referred to the Syſtem of NAVIGATION.

Having gone through the eſſential parts of Aſtronomy, it only remains that I inform the ſubſcribers to the Encyclopædia, that in ſome of the calculative Tables, I have been favoured with the aſſiſtance of Mr. Moody, whoſe mathematical abilities render him extremely capable of undertaking a buſiveſs of this nature; and that in digeſting the whole, recourſe has been had to every valuable work on this ſubject, that has come to our knowledge; the principal of which are the Treatiſes of Dr. Gregory, Keil, Dr. Halley, M. De la Caille, Dr. Long, Robertſon, Heath, Emerſon, De la Lande, &c. together with the Improvements of Dr. Herſchell, &c. collected from the Tranſactions of the Royal Society, and a variety of other miſcellaneous publications.

It has been our ſtudy to make this Syſtem full and comprehenſive, ſo that, with due attention, a perſon may attain a competent knowledge of Aſtronomy, without any other Treatiſe; and by purchaſing a good ſet of Aſtronomical Tables, he will be thoroughly qualified for making actual Calculations of the Motions of the celeſtial Bodies, ſuch as calculating the places of the Sun, Moon, and Planets, for any propoſed time; their conjunctions and oppoſitions with each other; predicting Eclipſes, &c.

I cannot take leave of this ſubject, without expreſſing how much we have been indebted to Mr. ADAMS, (*Mathematical and Aſtronomical Inſtrumental Maker, in Fleet-ſtreet*) *for his encouragement of our undertaking, by ſending us ſeveral of his inſtruments to have drawings from; as it is a point of no ſmall conſequence to practitioners in Aſtronomy, that they ſhould have the moſt neceſſary, and thoſe the moſt accurate Inſtruments that can be made.*

The Uſe of the Globes will be given in the Syſtem of GEOGRAPHY; *alſo other matters relating to Aſtronomy will be inſerted in the* Syſtems of PHILOSOPHY and NAVIGATION, *and under their reſpective Heads in different parts of the* ENCYCLOPÆDIA.

MUSEUM

ASTYNOMI, in Grecian antiquity, were magiſtrates in Athens. correſponding to the ædiles of the Romans; they were ten in number.

ASYLUM, a ſanctuary, or place of refuge, where criminals ſhelter themſelves from the hands of juſtice.

The aſyla of altars and temples were very ancient; and likewiſe thoſe of tombs, ſtatues, and other monuments of conſiderable perſonages.

Thus, the temple of Diana at Epheſus was a refuge for debtors, the tomb of Theſeus for ſlaves. Among the Romans, a celebrated aſylum was opened by Romulus, between the mounts Palatine and Capitoline, in order to people Rome, for all ſorts of perſons indiſcriminately, fugitive ſlaves, debtors, and criminals of every kind. The Jews had their aſylæ; the moſt remarkable of which were, the ſix cities of refuge, the temple, and the altar of burnt-offerings.

It was cuſtomary among the Heathens to allow refuge even to the vileſt and moſt flagrant offenders; and it was by this means, and with ſuch inhabitants, that Thebes, Athens, and Rome, were firſt ſtocked.

The emperors Honorius and Theodoſius granted the like immunities to convents; ſo that convents in a little time became a ſort of fortreſſes; where the moſt notorious villains were in ſafety, and braved the power of the magiſtrate.

Theſe privileges were extended not only to the churches and church-yards, but alſo to the biſhops houſes; whence the criminal could not be removed, without a legal aſſurance of life, and an entire remiſſion of the crime alledged to his charge.

But at length theſe aſylæ or ſanctuaries were ſtripped of their immunities, as they tended only to make guilt and libertiniſm more bold and daring.

ASYMMETRY, implies the want of proportion between the parts of any thing; being contrary to ſymmetry.

ASYMPTOTE, in geometry, is a line which continually approaches nearer to another; but, though continued infinitely, will never meet with it.

In a ſtrict ſenſe the term aſymptotes is appropriated only to right lines, which approach very near to curves of which they are ſaid to be aſymptotes; but if they and their curves are indefinitely continued, they will never meet.

ASYNDETON, in grammar, is a figure which omits the conjunctions in a ſentence.

As in *veni, vidi, vici,* where ET is left out: or in that of Cicero concerning Catiline, *abiit, exceſſit, evaſit, erupit.*

Aſyndeton ſtands oppoſed to polyſyndeton, where the copulatives are multiplied.

ATABULUS, in phyſiology, ſignifies a provincial wind in Apulia, of a dry pinching quality, and very noxious in its effects.

ATAMASCO, in botany, is a ſynonyme of the amaryllis or lily.

ATANTA, in botany, implies the African ſumach.

ATARAXY, was a term uſed by the ſtoics and ſceptics, to denote that calmneſs of mind which ſecures us from all emotions ariſing from vanity and ſelf-conceit.

ATAXY in a general ſenſe, implies the want of order: with phyſicians, it ſignifies irregularity of criſes and paroxyſms of fevers.

ATCHE, in commerce, is a ſmall ſilver coin uſed in Turkey, and of the value of one-third of the Engliſh penny.

ATCHIEVEMENT, in heraldry, denotes the arms of a perſon or family, with all the exterior ornaments of the ſhield; as helmet, mantle, creſt, ſcrolls, and motto, together with ſuch quarterings as may have been acquired by alliances, all marſhalled in order.

ATCHIEVE, ſignifies to perform great actions or exploits.

ATELLANÆ, in Roman hiſtory and antiquities, indicate a kind of theatricals uſually repreſented at Rome; partaking alike of the Greek ſatyræ and the Engliſh farce: hence, thoſe entertainments are denominated ludicrous treats of wit, or burlettas.

ATELEIA, in polity, denotes an exemption from all manner of public taxes or other impoſitions.

ATEMPO Giusto, in muſic, ſignifies to ſing or play in an equal, true, and juſt time.

ATH, Atha, or Athe, in Engliſh hiſtory, denotes the oath taken by the Anglo Saxons, on appointments in government as the ſolemn faith of office. A practice worthy of imitation.

ATHAMADULET, is the title of the prime miniſter of the Perſian empire, as the grand vizir is of the Turkiſh empire. He is great chancellor of the kingdom, preſident of the council, ſuperintendent of the finances, and charged with all foreign affairs.

ATHAMANTA, Spignel, in botany, is a genus of the digynia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 45th order, Umbellatæ. The fruit is oblong and ſtraited; and the petals are inflected and emarginated. There are nine ſpecies; but none of them merit particular notice, except the cretenſis, daucus creticus, which grows wild in the Levant and the warmer parts of Europe. The flower-ſtalk riſes about two feet high, and ſends forth many branches, terminated at the top by compound umbels, compoſed of near 20 ſmall ones. Theſe have white flowers with five petals, which are ſucceeded by oblong, hairy, channelled fruit, divided into two parts, containing one oblong hairy ſeed, which have a warm biting taſte, with an agreeable aromatic ſmell. They are kept in the ſhops as a medicine, and are carminative, and diuretic; but are little uſed in practice.

ATHANASIA, Tanzy, Goldilocks, in botany, is a genus of the polygamia æqualis order, belonging to the ſyngeneſia claſs of plants; and in the natural method ranking under the 49th order, Compoſitæ diſcoides. The receptacle is chaffy; as is the pappus; the calyx is imbricated. There are 20 ſpecies, all tender plants except one; and none of them poſſeſſed of beauty, or any remarkable property.

ATHANATE, in Engliſh antiquity, implies the act of raiſing or enobling a perſon, as the reward of merit; which in former ages was ſo rigidly and ſcrupulouſly attended to, that the former life of the candidate was examined into, leaſt any impediment ſhould lay in the way, to eclipſe the honour conferred by the royal hand.

Was the ſame method now to be purſued, the third eſtate of national repreſentation would, in all probability, be very few in number when compared with the preſent body politic.

ATHANATI, in Perſian antiquity, ſignifies a body of cavalry, conſiſting of 10,000 men, always complete. They were called immortal, becauſe, when one of them happened to die, another was immediately appointed to ſucceed him.

ATHANOR, in chemiſtry, implies a furnace ſo conſtructed that it always maintains an equal heat, which laſts a long time without addition of fuel.

The body of the athanor has nothing in it particular, and is conſtructed like ordinary furnaces. But at one of its ſides, there is an upright hollow tower, which communicates with the fire-place, by one or more ſloping openings. This tower ought to have a lid which exactly cloſes its upper opening.

When the athanor is to be uſed, as much lighted coal is put in the fire-place as is judged neceſſary, and the tower is filled to the top with unlighted fuel. The tower is then to be exactly cloſed with its lid. As faſt as the coal in the fire-place is conſumed, that in the tower falls down and ſupplies its place. As the coal contained in the tower has no free communication with the external air, it cannot burn till it falls into the fire-place.

ATHEISM, implies the diſbelief of a diety.

ATHEIST, denotes a perſon who does not believe in the exiſtence of a deity.

ATHELING, Adeling, Edling, Ethling, or Etheling, among Anglo-Saxons, was a title of honour properly belonging to the heir apparent, or preſumptive, to the crown.

This honourable appellation was firſt conferred by king Edward the confeſſor on Edgar, to whom he was great uncle, when, being without any iſſue of his own, he intended to make him his heir.

ATHENÆA, in antiquity, was a feaſt celebrated by the ancient Greeks in honour of Minerva, who was called Athene.

ATHENÆUM, in antiquity, denoted a public place in which the profeſſors of the liberal arts held their aſſemblies; the rhetoricians declaimed, and the poets rehearſed their performances.

Thoſe places, of which there were a great number at Athens, and Rome, were built in the manner of amphitheatres, encompaſſed with ſeats, called *cunei.*

ATHENATORIUM, in chemiſtry, denotes a thick glaſs cover, generally uſed to encloſe a curcubit.

ATHENIPPÆ, among oculiſts, denote the ſeveral collyriums the eye is ſubject to.

ATHERINA, in ichthyology, is a genus of fiſhes of the order of abdominales.

The characters are, the upper jaw, plain, the rays of the branchioſtege membrane are ſix, with ſhining ſide belts.

There are two ſpecies, viz.

1. The hepſetus with 12 rays in the hinder fin. A native of the Engliſh channel and the mediterranean, uſually denominated a ſmelt. The length is above 4¼ inches, and tail forked. The fiſh is ſemipellucid, covered with ſcales; the colour ſilvery, tinged with yellow: beneath the ſide-line is a row of ſmall black ſpots.

2. The menidea, with 24 rays in the fin next the anus. This is a very ſmall pellucid fiſh, with many black points interſperſed; it has many teeth in the lips, but none in the tongue or jaws. It is found in the freſh waters of Carolina, and ſpawns in April.

ATHEROMA, in medical language, implies a tumor without pain or diſcoloration of the ſkin, containing, in a membranous bag, matter reſembling pap, intermixed with hard and ſtony particles. Theſe kind of tumors are eaſily cured by inciſion.

ATHLETÆ, in antiquity, were perſons of ſtrength and agility, diſciplined to perform in the public games.

Under Athletæ were comprehended wreſtlers, boxers, runners, leapers, throwers of the diſk, and thoſe practiſed in other exerciſes exhibited in the Olympic, Pythian, and other ſolemn ſports; for the conquerors in which there were eſtabliſhed prizes.

ATHLETIC Habit, denotes a ſtrong conſtitution of body. Anciently it ſignified a full fleſhy corpulent ſtate, ſuch as the athletæ endeavoured to arrive at.

The athletic habit is eſteemed the higheſt pitch of health: yet is it dangerous, and the next door to diſeaſe; ſince, when the body is no longer capable of being improved, the next alteration muſt be for the worſe.

ATHLOPHETÆ, in antiquity, were officers who preſided at public games to adjudge the prizes to the victors.

ATHWART, in navigation, is ſynonimous with acroſs the line of the courſe.

Athwart *the Fore-foot*, is a phraſe that denotes the flight of a cannon ball from one ſhip acroſs the courſe of another, to intercept the latter, and oblige her to ſhorten ſail, that the former may come near enough to examine her.

Athwart *Hauſe*, in ſea language, expreſſes the ſituation of a ſhip, when ſhe is driven by wind or tide, or any other accident, acroſs the fore-part of another.

Athwart *Ships*, ſignifies reaching acroſs ſhips from one ſide to the other.

ATIBAR, is the name by which the inhabitants of the kingdom of Gago in Africa call gold duſt; from which word Europeans, and eſpecially the French, have compoſed the word *tibir*, which alſo ſignifies gold duſt among thoſe who trade in that commodity.

ATLANTIDES, in aſtronomy, is a denomination given to the Pleiades, or ſeven ſtars, ſometimes alſo called Vergilliæ. They are ſo called, as being reputed by the poets to have been the daughters either of Atlas or his brother Heſperus, who were tarnſlated into heaven.

ATLAS, in matters of literature, denotes a book of univerſal geography, containing maps of all the known parts of the world.

Atlas, in commerce, implies a ſilk ſatin, manufactured in the Eaſt Indies. There are ſome plain, ſome ſtriped, and ſome flowered, the flowers of which are either gold or only ſilk.

There are atlaſſes of all colours; but moſt of them falſe, eſpecially the red and the crimſon.

The manufacture of them is admirable; the gold and ſilk being worked together after ſuch a manner as no workmen in Europe can imitate; yet they are very far from having that fine gloſs and luſtre which the French know how to give to their ſilk ſtuffs.

In the Chineſe manufactures of this ſort, they gild paper on one ſide with leaf gold; then cut it in long ſlips, and weave it into their ſilks; which makes them, with very little coſt, look very rich and fine. Theſe ſlips are twiſted about ſilk threads, ſo artificially, as to look finer than gold thread, though it is of no great value.

Atlas, in anatomy, is the name of the firſt vertebræ of the neck, which ſupports the head.

Atlas, in architecture, implies the figures which repreſent the human form, and bear up or ſupport a balcony or any member on their head or ſhoulders.

In ſculpture and ſtatuary, the ſame definition takes place.

Atlas, in geography, ſignifies an high mountain in Africa. Hence the mythological fable of Atlas, king of this ſtupendous mount, bearing the heavens on his ſhoulders. The alluſion is figurative, only implying its vaſt height.

ATMOSPHERE, a word generally uſed to ſignify the whole maſs of air, ſurrounding the earth to a conſiderable height.

ATOM, in philoſophy, denotes a particle of matter, ſo minute, as to admit of no diviſion. Atoms are the *minima naturæ*, and are conceived to be the firſt principles or component parts of all phyſical magnitude.

ATOMICAL Philosophy, or the doctrine of atoms, implies a ſyſtem which, from the hypotheſis that atoms are endued with gravity and motion, accounted for the origin and formation of things.

This philoſophy was firſt broached by Moſchus, ſome time before the Trojan war; but was much cultivated and improved by Epicurus; whence it is denominated the *Epicurean philoſophy*.

ATONEMENT, implies the ſame as Expiation, under which head this article is explained.

ATONICS, in grammar, imply unaccepted ſyllables.

ATONY, in medicine, denotes a defect of tune or tenſion, or a laxity or debility of the ſolids of the body.

ATRA Bilis, Black Bile, or Melancholy, in phyſic, according to the ancients it hath a two fold origin: 1ſt, From the groſſer parts of the blood, and this they called the *melancholy humour*. 2d, From yellow bile being highly concocted.

Dr. Percival, in his eſſays Med. and Exp. ſuggeſts, that it is the gall rendered acrid by a ſtagnation in the gall-bladder, and rendered viſcid by the abſorption of its fluid parts.

Bile in this ſtate diſcharged into the duodenum, occaſions an univerſal diſturbance and diſorder until it is evacuated.

Some deſcribe this kind of bile as being acid, harſh, corroding, and, when poured on the ground, bubbling up, and raiſing the earth after the manner of a ferment.

Dr. Percival ſays, that by the uſe of the *infuſ. ſenæ limoniet.* warmed with the *tinct. columb.* he had checked the vomitings occaſioned by this matter.

ATRACTYLIS, Distaff Thistle, in botany, a genus of the polygamia æqualis order, belonging to the ſyngeneſia claſs of plants; and in the natural method ranking under the 49th order, Compoſitæ capitatæ. The corolla is radiated; and each of the little corollæ of the radius has five points like teeth.

There are three ſpecies, viz. 1. The cancellata, or ſmall cnicus, is an annual plant riſing about nine inches high, with a ſlender ſtem, garniſhed with hoary leaves, having ſpines on their edges. At the top of theſe branches are ſent out two or three ſlender ſtalks, each terminated by a head of flowers like thoſe of the thiſtle. The empalement is curiouſly netted over, and is narrow at the top, but ſwelling below; and contains many florets of a pale purple colour. Theſe are each ſucceeded by a ſingle downy ſeed, which in cold years do not ripen in this country.

2. The humilis, or purple prickly cnicus, raiſes about a foot high, with indented leaves, having ſmall ſpines on their edges.

3. The gummifera, or prickly gum-bearing cnicus, known among phyſicians by the name of *carline thiſtle*.

Theſe thiſtles lie cloſe on the ground; and between them the flower is ſituated, without a ſtalk, and having many florets incloſed in a prickly empalement. Thoſe on the border are white; but ſuch as compoſe the diſk are of a yellowiſh colour.

All theſe plants are natives of the warm parts of Europe, as Spain, Sicily, and the Archipelago iſlands, from whence their ſeeds muſt be procured. They muſt be ſown upon an open bed of light earth, where the plants are to remain; and when the plants come up, they ſhould be thinned. ſo as to leave them three or four inches aſunder. The roots of the ſecond will laſt two or three years, and the third is a perennial plant.

The root of the third ſort was formerly uſed as a warm diaphoretic and alexipharmic; but it never came much into uſe in England, and the preſent practice has entirely rejected it.

ATRÆTI, in medicine, denote infants having no perforation in the anus, or perſons imperforated in the vagina or urethra.

ATRAGENE, in botany, is a genus of the polyandria order belonging to the polygamia claſs of plants.

The calyx has four leaves; the petals are 12; and the ſeeds are candated.

There are three ſpecies, all natives of the Eaſt, but merit no deſcription.

ATRAPHAXIS, in botany, is a genus of the diagynia order, belonging to the hexandria claſs of plants; and in the natural method ranking under the 12th order, Holoraceæ. The calyx has two leaves; the petals are two, and ſinuated; and there is but one ſeed. There are two ſpecies, both natives of warm countries, but meriting no particular deſcription.

ATREBATII, in Engliſh hiſtory, imply a race of people ſeated next to the Bibroci, in part of Berkſhire and part of Oxfordſhire. This was one of thoſe Belgic colonies which had come out of Gaul into Britain, and there retained their ancient name. Atrebatii were a tribe of the Belgæ, who inhabited that country which is now called Artois.

ATRESIA, in medicine, implies perforation, or in other words, ſignifies the caſe of perſons wanting a natural aperture.

ATRETI, in ſcientific language, imply thoſe perſons in whom the anus or genitals are imperforate.

ATRICILLA, in ichthyology, denotes a variety of the larus, of which it is a ſynonyme.

ATRIDALLIS, in ſcience, implies the knowledge of things, conſidered in an abſtracted ſenſe. Hence the theory of arts is ſaid to be atridalliſiac.

ATRIENSES, in antiquity, were upper ſervants in great families at Rome, who had the care and inſpection of the atria and the things lodged in it: they acted as procurators, or agents, of their maſter, in ſelling goods, &c. To their care were committed the ſtatues and images of the maſter's anceſtors, &c. which were placed round the atrium; and which they carried in proceſſion at funerals, &c. They were cloathed in a ſhort white linen habit, to diſtinguiſh them, and prevent their loitering from home.

ATRIP, in nautical language, is a term applied either to the anchor or top ſails. The anchor is atrip, when it is drawn out of the ground in a perpendicular direction, either by the cable or buoy rope. The top ſails are atrip, when they are hoiſted up to the maſt head, or to their utmoſt extent.

ATRIPLEX, Orach, or Arach, in botany, is a genus of the monœcia order, belonging to the polygamia claſs of plants; and, in the natural method, ranking under the 12th order, Holoraceæ. The calyx of the hermaphrodite flower has five leaves; there is no corolla; the ſtamina are five, and the ſtylus is byfid; the ſeed is one, and depreſſed. There are 12 ſpecies.

1. The hortenſis, or garden orach, was formerly cultivated in gardens, and uſed as a ſubſtitute for ſpinage, to which it is ſtill preferred by ſome, though in general it is diſliked by the Engliſh; though it ſtill maintains its credit in France and Ireland. There are three or four varieties of this plant, whoſe only difference is their colour; one is a deep green, another a dark purple, and a third with green leaves and purple borders.

2. The halimus, or broad leaved orach, was formerly cultivated in gardens as a ſhrub.

3. The petulacoides, or ſhrubby ſea-orach, grows wild by the ſea ſide in many parts of this kingdom. It is a low under ſhrub, ſeldom riſing above two feet and an half, or at moſt three feet high; but becomes very buſhy.

The firſt ſort is annual, ſo muſt be propagated by ſeeds. This ſpecies is an article of the materia medica; a decoction of the leaves is recommended in coſtiveneſs, where the patient is of a bilious diſpoſition. The ſecond ſort may be propagated by cuttings. The third ſort requires very little culture. It may be alſo propagated from cuttings, and is to be planted in a poor gravelly ſoil.

ATRIUM, in eccleſiaſtical antiquity, denotes an open place or court before a church, making part of what was called the narthex or antetemple. The atrium in the ancient churches was a large area or ſquare plat of ground, ſurrounded with a portico or cloyſter, ſituate between the porch or veſtible and the body of the church.

Atrium, is alſo uſed, in the canon law, to ſignify the cemetry or church yard.

ATROPA, Deadly Night Shade, in botany, is a genus of the monogynia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 25th order, Luridæ. The corolla is campanulated; the ſtamina are diſtant; the berry is globular, and conſiſts of two cells.

There are five ſpecies, of which the three following are the moſt remarkable, viz.

1. The belladonna which grows wild in many parts of Britain. It hath a perennial root, which ſends out ſtrong herbaceous ſtalks of a pale purple colour, which riſe to the height of five feet, garniſhed with entire oblong leaves, which towards autumn change to a purple colour. The flowers are large, and come out ſingly between the leaves, upon long foot ſtalks; bell ſhaped, and of a duſky colour on the outſide, but purpliſh within. After the flower is paſt, the germen turns to a large round berry a little flated at the top. It is firſt green; but when ripe, turns to a ſhining black, ſits cloſe upon the empalement, and contains a purple juice of a nauſeous ſweet taſte, and full of ſmall kidney ſhaped ſeeds.

2. The fruteſcens is a native of Spain, and riſes with a ſhrubby ſtem to the height of eight feet; dividing into many branches garniſhed with round leaves, in ſhape like thoſe of the ſtorax tree.

The flowers come out between the leaves on ſhort foot ſtalks, ſhaped like thoſe of the former, but much leſs; of a dirty yellow colour, with a few brown ſtripes: but theſe are never ſucceeded by berries in this country.

3. The herbacea, with an herbaceous ſtalk, is a native of Campeachy. This hath a perennial root, which puts forth ſeveral channelled herbaceous ſtalks riſing about two feet.

4. The mandragora, or mandrake, which has been diſtinguiſhed into the male and female. The male mandrake has a very large, long, and thick root; it is largeſt at the top or head, and from thence gradually grows ſmaller.

The female mandrake perfectly reſembles the other in its manner of growth; but the leaves are longer and narrower, and of a darker colour, as are alſo the ſeeds and roots. It grows naturally in Spain, Portugal, Italy, and the Levant.

The firſt ſpecies, which is markable for its poiſonous qualities, is very ſeldom admitted in gardens, nor ſhould it ever be cultivated or allowed to grow in thoſe places to which children have acceſs. The other kinds are propagated by ſeeds, and placed in a ſtove, as is requiſite for the more tender plants.

Moſes informs us, (Gen. xxx. 14.) that Reuben, the ſon of Leah, being in the field, happened to find mandrakes, which he brought home to his mother. Rachel had a mind to them, and obtained them from Leah, upon condition that ſhe ſhould conſent that Jacob ſhould be Leah's bedfellow the night following. The term דודאים *dudaim*, here made uſe of by Moſes, is one of thoſe words of which the Jews at this day do not underſtand the true ſignification. Some tranſlate it *violets*, others *lilies*, or *jeſſamine*. Junius calls it *agreeable flowers*; Codurquus makes it *truffle*, or *muſhroom*; and Calmet will have it to be the *citron*. Thoſe that would ſupport the tranſlation of *mandrakes* plead, that Rachel being barren, and having a great deſire to conceive, coveted Leah's mandrakes, it may be preſumed, with a view to its prolific virtues. The ancients have given to mandrakes the name of the *apples of love*, and to Venus the name of *mandragoritis*; and the Emperor Julian, in his epiſtle to Calixenes, ſays, that he drinks the juice of mandrakes to excite amorous inclinations.

ATROPHY, in medicine, implies a diſeaſe which the body, or ſome of its parts, do not receive the neceſſary nutriment, but waſte and decay inceſſantly.

ATROPOS, in mythology, was the name of the third of the Parcæ, or Fates, whoſe buſineſs it was to cut the thread of life.

ATTACHMENT, in the Engliſh law, implies the taking or apprehending a perſon by virtue of a writ or precept. It is diſtinguiſhed from an arreſt, by proceeding out of a higher court by precept or writ; whereas the latter proceeds out of an inferior court by precept only. An arreſt lies only on the body of a man; but an attachment lies againſt the goods or againſt both the body and goods.

An attachment by writ differs from diſtreſs, in not extending to lands, as the latter does; nor does a diſtreſs touch the body, as an attachment does.

Attachment *out of the High Court of Chancery*, is obtained upon an affidavit made, that the defendant was ſerved with a ſubpœna, and made no appearance; or it iſſues upon not performing ſome order or decree. Upon the return of this attachment by the ſheriff, *quod non eſt inventus in balliva ſua*, another attachment, with a proclamation, iſſues; and if he ſtill refuſes to appear, then a commiſſion of rebellion.

Attachment *of the Foreſt*, is one of the three courts held in the foreſt. The loweſt court is called the *court of attachment*, or *wood mote court*; the mean, *ſwan mote*; and the higheſt, the *juſtice in eyre's ſeat*. The court of attachments has its name from the verdurers of the foreſt having no other authority in it, but to receive the attachments of offenders againſt vert and veniſon taken by the foreſters, and to enroll them, that they may be preſented or puniſhed at the next juſtice in eyre's ſeat. This attachment is by three means: 1. by goods and chattels; 2. by body, pledges, or main prize; 3. or by the body only. This court is held every 40 days throughout the year; and is from thence called the *forty days court*.

Foreign Attachment, implies an attachment of money or goods found within a liberty or city, to ſatisfy ſome creditor within the ſame. By the cuſtom of London, and ſeveral other places, a man can attach money or goods in the hands of a ſtranger, to ſatisfy himſelf provided he can produce evidence, but not otherwiſe.

ATTACK, is a violent attempt upon any perſon or thing, an aſſault, or the act of beginning a combat or diſpute.

Attack, in the military art, implies an effort made to force a poſt, break a body of troops, &c.

Attack *of a Siege*, is a furious aſſault made by the beſiegers with trenches, covers, mines, &c. in order to make themſelves maſters of a fortreſs, by ſtorming one of its ſides.

ATTACOTTI, were an ancient people of Britain, mentioned by Ammianus, Marcellinus and St. Jerome, as well as in the Notitia Imperii.

They are repreſented as allies and confederates of the Scots and Picts, and therefore probably their neighbours: though their preciſe ſituation has not been determined by antiquaries.

ATTAINDER, in law, is ſaid to lay, when ſentence of death, the moſt terrible and higheſt judgment in our laws, is pronounced, the immediate inſeperable conſequence by the common law, is attainder. For then it is clear beyond all diſpute, that the criminal is no longer fit to live, but is to be cut off as a bane to ſociety, the law ſets a note of infamy upon him, puts him out of its protection, and takes no farther care of him than barely to ſee him executed. He is then called attaint, attinctus, ſtained, or blackened. He no longer has any credit or reputation; nor can he be a witneſs in any court; neither is he capable of performing the functions of another man: for by an anticipation of his puniſhment, he is already dead in law. This is after judgment: for there is great difference between a man convicted, and attainted. After conviction only, a man is liable to none of theſe diſabilities: for there is ſtill in contemplation of law a poſſibility of his innocence. Something may be offered in arreſt of judgment: the indictment may be erroneous, which will render his guilt uncertain, and upon which the preſent conviction may be quaſhed: he may obtain a pardon, or be allowed the benefit of clergy.

Attainders may be reverſed or falſified, (i. e. proved to be falſe) by writ of error, or by plea. If by writ of error, it muſt be by the king's leave, &c. and when by plea, it may be by denying the treaſon, and pleading a pardon by act of parliament.

Perſons may be attainted by act of parliament. Acts of attainder of criminals have been paſſed in ſeveral reigns, on the diſcovery of plots and rebellions, from the reign of king Charles II. when an act was made for the attainder of ſeveral perſons of the murder of king Charles I.

Among acts of this nature, that for attainting Sir John Fenwick, for conſpiring againſt king William, is the moſt remarkable; it being made to attaint and convict him of high treaſon on the oath of one witneſs, juſt after a law had been enacted, "That no perſon ſhould be tried or attainted of high treaſon where corruption of blood is incurred, but by the oath of two lawful witneſſes, unleſs the party confeſs, ſtand mute, &c." Stat. 7. and 8. W. III. cap. 3. But in the caſe of Sir John Fenwick there was ſomething extraordinary; for he was indicted of treaſon on the oaths of two witneſſes, though but only one could be produced againſt him on his trial; this argues a partial and unjuſt procedure, much to the diſgrace of the reign which permitted ſuch a flagrant breach of the laws for the protection of the ſubject, merely to gratify miniſterial influence and arbitrary meaſures of the crown.

ATTAINT, in law, is a writ that lies after judgment againſt a jury of twelve men that have given falſe verdict in a court of record, in an action real or perſonal, where the debt or damages amount to above 40s. Stat. 5. and 34 Ed. III. c. 7.

It is called attaint, becauſe the party that obtains it endeavours thereby to ſtain or taint the credit of the jury with perjury, by whoſe verdict he is grieved.

The jury who are to try this falſe verdict muſt be twenty four, and are called the grand jury; for the law wills not that the oath of one jury of twelve men ſhould be attainted or ſet aſide by an equal number, nor by leſs indeed than double the former. And he that brings the attaint can give no other evidence to the grand jury, than what was originally given to the petit jury. For as their verdict is now trying, and the queſtion is whether or no they did right upon the evidence that appeared to them, the law adjudged it the higheſt abſurdity to produce any ſubſequent proof upon ſuch trial, and to condemn the prior juriſdiction for not believing evidence which they never knew. But thoſe againſt whom it is brought are allowed, in the affirmance of the firſt verdict, to produce new matter: becauſe the petit jury may have formed their verdict upon evidence of their own knowledge, which never appeared in court; and becauſe very terrible was the judgment which the common law inflicted upon them, if the grand jury found their verdict a falſe one. The judgment was; 1. That they ſhould loſe their liberam legem, and become for ever infamous.

2. That they ſhould forfeit all their goods and chattels.

3 That their lands and tenements ſhould be ſeized into the king's hands.

4. That their wives and children ſhould be thrown out of doors.

5. That their houſes ſhould be raſed to the ground.

6. That their trees ſhould be rooted up.

7. That their meadows ſhould be ploughed.

8. That their bodies ſhould be caſt into jail.

9. That the party ſhould be reſtored to all that he loſt by reaſon of the unjuſt verdict.

But as the ſeverity of this puniſhment had its uſual effect, in preventing the law from being executed, therefore by the ſtatute 11 Hen. VII. c. 24. revived by 23 Hen. VIII. c. 3. and made perpetual by 13 Eliz. c. 25. it is allowed to be brought after the death of the party, and a more moderate puniſhment was inflicted upon attainted jurors; viz perpetual infamy, and if the cauſe of action were above 40l. value, a forfeiture of 20l. a piece by the jurors; or, if under 40l. then 5l. a piece; to be divided between the king and the party injured. So that a man may now actually bring an attaint either upon the ſtatute or at common law, at his election; and in both of them may reverſe the former judgment. But the practice of ſetting aſide verdicts upon motion, and granting new trials, has ſo ſuperſeded the uſe of both ſorts of attaints, that there is hardly any inſtance of an attaint later than the 16th century. Vide Blackſtone's Commentaries on the Laws of England.

Attaint, among farriers, is a knock or hurt in a horſe's leg, proceeding either from a blow with another horſe's foot, or from an over reach in froſty weather, when a horſe, being rough-ſhod, or having ſhoes with long caulkers, ſtrikes his hinder feet againſt his fore leg.

ATTAINTED, in law, implies a perſon's being under attainder.

ATTALICÆ Vestes, in antiquity, were garments made of a kind of cloth of gold. They took the denomination from Attalus, ſurnamed Philometer, a wealthy king of Pergamus, who was the firſt, according to Pliny, who procured gold to be woven into cloth.

ATTELABUS, in entomology, is a genus of inſects belonging to the order of coleoptera or beetle kind. It has four wings, of which the ſuperior are cruſtaceous, and ſerve as a ſheath or cover to the inferior, which are membranous. The head tapers behind, and is inclined; the feelers turn thicker towards the apex. The ſpecies are 13; viz.

1. The coryli is black, with red elytra or cruſtaceous wings.

2. The avellana is black, with the breaſt, feet, and elytra red.

3. The curculionoides is black, with red elytra and breaſt. The above three ſpecies frequent the leaves of the hazel and fillbert nut trees.

4. The ſurinamenſis has a double indentation or two teeth in the top of the elytra. It is a native of Surinam.

5. Then penſilvanicus is black, with red elytra, a black belt round the middle, and another towards the apex of the elytra. It is a native of Philadelphia and parts adjacent.

6. The melanurus is black, with teſtaceous elytra, black at the apex. It is a native of Sweden.

7. The betula has ſaltatory or ſpringy legs, and the whole body is of a dark red colour. It frequents the leaves of the birch tree.

8. The formicarius is black, with red elytra, and a double white belt towards the baſe. It is a native of Europe.

9. The ſipylus is green, with a hairy breaſt, and a double yellow belt upon the elytra.

10. The apiarius is bluiſh, with red elytra, and three black belts. It is a native of Germany.

11. The mollis is yellowiſh and hairy, with pale elytra, and three belts. It is a native of Europe.

12. The ceramboides is of a blackiſh red colour, and the elytra is furrowed. It frequents the ſpongy boletus, a ſpecies of muſhroom.

13. The bupreſtoides is of a dark red colour, with a globular breaſt, and nervous elytra. It is a native of all parts of Europe.

ATTENTION, implies a due application of the ear, or the mind, to any thing ſaid or done, in order to acquire a knowledge of it. The word is compounded of *ad*, to, and *tendo*, I ſtretch.

Attention of mind is not properly an act of the underſtanding; but rather of the will, by which it calls the underſtanding from the conſideration of other objects, and directs it to the thing in hand. Yet nevertheleſs, our attention is not always voluntary: for an intereſting object ſeizes and fixes it beyond the power of controul.

Attention, or *Attentio*, in reſpect of hearing, is the ſtretching or ſtraining of the membrana tympani, ſo as to make it more ſuſceptible of ſounds, and better prepared to catch even a feeble agitation of the air.

According to the degree of attention, objects make a ſtronger or weaker impreſſion.

" Sounds, ſays Lord Bacon, are meliorated by the intenſion of the ſenſe, where the common ſenſe is collected moſt to the particular ſenſe of hearing, and the ſight ſuſpended. Therefore ſounds are ſweeter, as well as greater, in the night than in the day; and I ſuppoſe they are ſweeter to blind men than to others; and it is manifeſt, that between ſleeping and waking, when all the ſenſes are bound and ſuſpended, muſic is far ſweeter than when one is fully waking."

Attention is requiſite even to the ſimple act of ſeeing: the eye can take in a conſiderable field at one look; but no object in the field is ſeen diſtinctly but that ſingly which fixes the attention, but in a profound reverie that totally occupies the attention, we ſcarce ſee what is directly before us.

In a train of perceptions, no particular object makes ſuch a figure as it would do ſingly, and apart; for when the attention is divided among many objects, no particular object is intitled to a large ſhare. Hence, the ſtillneſs of night contributes to terror, there being nothing to divert the attention.

ATTENUANTS, or Attenuating *Medicines*, are ſuch as ſubtilize and break the humours into finer parts; and diſpoſe them for motion, circulation, and excretion.

They are of very extenſive uſe in phyſic, and come under different denominations, according to the different effects they produce. When tenacious and viſcid juices ſtagnate in the cavities of the veſſels, and obſtruct the minute ducts of the viſcera emunctories, theſe medicines by their inciding and attenuating quality, diſcharge the humours, and remove the obſtructions; for which reaſon they are not improperly called aperients.

Thoſe medicines produce ſo great a variety of effects, that it is proper we ſhould be well acquainted with their ſeveral kinds, when apprporiated to their ſeveral diſorders, and know which will prove moſt ſerviceable in each.

Hoffman ſays, the diſſolving and attenuating of viſcid crudities in the ſtomach and primæ viæ, is well anſwered by the roots of arum, acorus, pepper, ginger, and the like; as alſo by ſal ammoniac, vitriolated tartar, fixed alkaline ſalts, and the ſimple or dulcified ſpirit of ſalt.

When crude unconcocted humours are to be evacuated by ſtool, this intention is very well anſwered by the neutral ſalts, as the ſalts of the purging waters, and the ſal polycreſtum, with a ſufficient quantity of a watery vehicle.

When viſcid humours, which occaſion diſorders of the breaſt, are to be attenuated and expectorated, the intention is moſt effectually anſwered by elecampane and orice roots; gum ammoniacum, myrrh, or benjamin, and balſam of Peru; or by regenerated tartar, oxymel of ſquills, a ſolution of crabs eyes in diſtilled vinegar, and the ſyrups of tobacco, and the like.

But when the maſs of blood is tainted by thick and tenacious ſordes, and the emunctories are by that means obſtructed, the humours contaminated by a ſaline ſulphureous and ſcorbutic dyſcracy, the moſt efficacious of the attenuants are the horſe radiſh, ſcurvy graſs, water and garden creſſes, muſtard, gum ammoniacum, benjamin, myrrh, the oil of fixed nitre, oil of tartar per deliquium, ſolutions of nitre, ſpirit of ſal ammoniac, ſalt of wormwood with lemon juice, and the ſalts of the medicinal or mineral ſprings.

Likewiſe when grumous or coagulated blood is occaſioned by contuſions, the intention is ſure to be anſwered by the roots of Solomon's ſeal, vinegar, and crabs eyes, regenerated tartar, and nitre prepared with antimony.

And alſo in caſes where the lymph has acquired a preternatural thickneſs and viſcidity, particularly in venereal caſes, the curative intention is moſt effectually anſwered by guaiacum, the acrid tincture of antimony, or calomel æthops mineral; which, when ſkilfully uſed, are of ſingular efficacy in diſſolving and attenuating the viſcid juices impacted in the glands of the liver.

ATTENUATION, in the materia medica, implies the act of attenuating; or making a fluid thinner than it was before.

It is alſo defined the dividing or ſeparating of the minute parts of any body, which before, by their mutual nexus or implication, formed a more continuous maſs.

ATTENUATION, among alchemiſts, ſignifies pulverization, or the act of reducting a body into an impalpable powder.

ATTESTATION, in law, ſignifies the ſignature of a witneſs who thereby becomes an evidence of legal acceptance; ſo that in courts of record the atteſtator is bona fide ſubſtantial evidence on behalf of either party, ſo as to prove the tranſaction to have actually taken place agreeably to the words of the deed or writing.

ATTESTED, in a general ſenſe, denotes the ſign manual of a perſon who was an eye witneſs to the performance of a thing.

ATTIC, in compoſition, implies the very eſſential parts of ſpeech, ſo as to collect the ſalt as it were of active underſtanding.

Attic, in architecture, implies a little kind of embelliſhment to any order, finiſhed on the coronating parts of a building.

Attic *Story*, among builders, denotes the higheſt loft in a houſe which is capable of being inhabited.

ATTILUS, in ichthyology, is a ſpecies of the ſturgeon genus, of which it is a ſynonymed variety.

ATTINGA, in amphibiology, indicates a variety of ſpecies of the diodon, in the order of Nantes; which, according to the claſſification and arrangement of the natural hiſtory of this work, will have a place in the Syſtem of Ichthyology, inſtead of the order it has hitherto occupied.

ATTIRE, in the menage, ſignifies the head or horns of a deer.

The attire of a ſtag, conſiſts of bur, pearls, beam, gutters, antler, ſur-antler, royal, ſur-royal, and crotches; but of a buck, of the bur, beam, brow-antler, advancer, palm, and ſpellers.

ATTITUDE, in painting and ſculpture, implies the geſture of a figure or ſtatue; ſo as to expreſs the action and ſentiments of the perſon repreſented.

ATTOLLENS, in anatomy, is an appellation given to ſeveral muſcles, otherwiſe called *levatores* and *elevatores*.

ATTORNEY *at Law*, ſignifies an officer in common law, of equal authority with a Procurator or Proctor of the civilians and canoniſts: one who is put in the place and ſtead of another, to manage his matters in law.

Formerly every ſuitor was obliged to appear in perſon, to proſecute or defend his ſuit, unleſs exempted by ſpecial licence under the king's letters patent, which is ſtill obſerved in criminal caſes.

And an idiot cannot to this day appear by attorney, but in perſon; as he is not competent in law to appoint a proper ſubſtitute: and upon his being brought before the court in ſo defenceleſs a condition, the judges are bound to take care of his intereſts, and admit the beſt plea in his behalf that any one preſent can ſuggeſt.

By divers ancient ſtatutes, of which the firſt is ſtatute Weſt. 2. c. 10. attornies may be made to proſecute or defend any action in the abſence of the parties to the ſuit. Attornies are in all points officers of the reſpective courts in which they are admitted at Weſtminſter hall, or elſewhere; and as they have many privileges on account of their attendance, ſo they are peculiarly ſubject to the cenſure and animadverſion of the judges.

No perſon can practiſe as an attorney in any court, but ſuch as are admitted and ſworn attornies of that particular court, unleſs by proxy; or in other words, deputed by one admitted of the court in which the record is made up for iſſue; in which caſe the acting attorney ſigns his own name by ſuch a perſon (ſigning the name of the ſuppoſed principal agent of the ſuit.)

To practice in chancery, it is neceſſary to be admitted a ſolicitor in that court: and by the ſtatute 22 Geo. II. c. 46. no perſon ſhall act as an attorney at the quarter-ſeſſions, but ſuch as have been regularly admitted into ſome ſuperior court of record.

Attornies in the exchequer are called agents.

Attornies are to take out certificates annually; and if reſident in London, Weſtminſter, or within the bills of mortality, or in Edinburgh, they are obliged to pay 5l. for the ſame; and in every other part of Great Britain 3l.

Theſe duties are under the management of the commiſſioners of ſtamps: and every acting ſolicitor, and other perſon as above, ſhall annually deliver in a note of his name and reſidence, to the proper officer of the court in which he practiſes; the entering officers are to certify notes delivered, and iſſue annual certificates, ſtamped as above, which muſt be renewed ten days before they expire. Refuſing to iſſue certificates, or iſſuing them improperly, is a penalty of 50l. with coſts and damages to the party aggrieved.

Acting without a certificate, or giving in a falſe place of reſidence, is alſo a penalty of 50l. and an incapacity to ſue for fees due. A ſtamped memorandum muſt be given to the proper officer, of the names of the parties in every action; and in ſuch caſes as uſed to require precipes with precipes alſo.

Officers who receive ſtamped memorandums, are to file the ſame, on penalty of 50l. and perſons not acting conformable to this act forfeit 5l.

Attorney *General*, in law, is a great officer under the king, made by letters patent. It is his province to exhibit informations or examinations, and proſecute for the crown, in matters of a criminal nature; and to file bills in the exchequer, for any thing concerning the profits of the crown; and others may bring bills againſt the king's attorney. It is the buſineſs of the attorney general upon any ſpecial matter of a criminal nature, in which his attendance is required, to ſit under the judges on the left hand of the clerk of the crown: but this is only upon ſolemn and extraordinary occaſions; for uſually he ſits within the bar in the face of the court.

ATTOURNMENT, or **Attornmene**, in law, ſignifies a transfer from one lord to another of the homage and ſervices of tenants, as an acknowledgement of duty to the new landlord.

ATTRACTION, in natural philoſophy, imports a general term uſed to denote the cauſe by which bodies tend towards each other, and cohere till ſeparated by ſome other power.

The firſt author in this country who adopted the notion of attraction was Dr. Gilbert, and the next the celebrated Lord Bacon. In France it was received by Fermat and Roberval; and in Italy by Galileo and Borelli. But till the famous Sir Iſaac Newton appeared, this principle was very imperfectly defined and applied.

There are divers particular kinds of attraction; as, gravity, magnetiſm, electricity, &c. which are ſo many different principles acting by different laws, and only agreeing in this, that we do not ſee any phyſical cauſes of the phænomena; but that, as to our ſenſes, they may really ariſe from ſome power or efficacy in ſuch bodies, by which they are enabled to act even upon diſtant bodies.

Attraction may be properly divided into two ſorts, viz.

1. That which extends to a ſenſible diſtance. Such are the attraction of gravity, found in all bodies; and the attraction of magnetiſm and electricity, found in particular bodies.

The attraction of gravity, called by mathematicians the centripetal force, is one of the greateſt and moſt univerſal principles in nature. From this ariſes all the motion, and conſequently all the mutation, in the great world. By it heavy bodies deſcend, and light ones aſcend; projectiles are directed, vapours, and exhalations riſe, and rains, &c. fall. By it alſo, rivers glide, the air preſſes, the ocean ſwells, &c. In effect, the motions ariſing from this principle make the ſubject of that extenſive branch of mathematics, called mechanics or ſtatics, with the parts or appendages of it, uſually called hydroſtatics, pneumatics, &c.

2. That which does not extend to ſenſible diſtances. Such is found to obtain in the minute particles of which bodies are compoſed, and which attract each other at or extremely near the point of contact, with a force much ſuperior to that of gravity, but which at any diſtance from it decreaſes much faſter than the power of gravity.

This latter kind of attraction was diſcovered by Sir Iſaac Newton, by whom the former was greatly improved.

ATTRIBUTE, in rhetoric, in a general ſenſe, implies that which agrees with ſome perſon or thing; or a quality determining ſomething to be performed after a certain manner.

Thus underſtanding is an attribute of mind, and extenſion an attribute of body.

That attribute which the mind conceives as the foundation of all the reſt, is called its eſſential attribute: thus extenſion is by ſome, and ſolidity by others, eſteemed the eſſential attributes of corporeal ſubſtances.

ATTRIBUTES, in theology, are the ſeveral qualities or perfections of the Divine nature of the Deity.

Attributes, in logic, are the predicates of ſubject, ſo that it may be affirmed or denied.

Attributes, in painting and ſculpture, are ſymbols added to ſeveral figures, to intimate their particular office and character. Thus the eagle is an attribute of Jupiter; a peacock, of Juno; a caduce, of Mercury; a club, of Hercules; and a palm, of Victory; a croſs, the enſign of Chriſtian faith, &c. &c.

ATTRIBUTIVES, in grammar, are ſuch words as are ſignificant of attributes; and thus include adjectives, verbs, and particles, which are attributes of ſubſtances; and adverbs, which denote the attributes of attributes.

Mr. Harris has introduced this diſtribution of words, and denominates the former *attributives of the firſt order*, and the latter *attributives of the ſecond order*.

ATTRITION, in mechanics, implies the rubbing or ſtriking of bodies one againſt another, ſo as to throw off ſome of their ſuperficies by exerciſe.

ATTROW, in botany, is a variety of the knotted graſs called kali, under which name the genus is explained. The ſynonymed epithet is only peculiar to the Guieneſe Africans, where it is uſed with ſucceſs to remove tumors and ſwellings.

ATTRUMMAPHOC, in botany, is a ſynonyme of the colutea. The former name is only uſed by the oculiſts of Guinea in Africa, where this plant is in high eſtimation as a preſervative againſt blindneſs.

AVA Ava, in botany, is a plant ſo called by the inhabitants of Otaheite, in the South ſea, from the leaves of which they expreſs an intoxicating juice. It is drank very freely by the chiefs and other conſiderable perſons, who vie with each other in drinking the greateſt number of draughts, each draught being about a pint; the women are reſtrained from the uſe of it.

AVADOUTAS, are a ſect of Indian Bramins, who in auſterity ſurpaſs all the reſt. The other ſects retain earthen veſſels for holding their proviſions, and a ſtick to lean on: but none of theſe are uſed by the Avadoutas, or ſtrolling mendicants. They only cover their nakedneſs with a piece of cloth; beſmearing their bodies with cow-dung. When hungry, ſome go into houſes, and, without ſpeaking, hold out their hand; eating on the ſpot whatever is given them. Others of this order retire to the ſides of holy rivers, and there eat the proviſions, which the peaſants bring to them.

AVALANCHES, in modern hiſtory, imply prodigious ſnow-balls that frequently roll down the mountains in Savoy, particularly Mount Blanc, to the extreme danger of ſuch adventurous travellers as attempt to aſcend thoſe ſtupendous heights. Some of theſe avalanches are 200 feet in diameter; being fragments of the ice-rocks which break by their own weight from the tops of the precipices.

AVANIA, in the Turkiſh legiſlature, denotes a fine for crimes of almoſt every denomination paid to the governor of the place. A Turkiſh governor takes this profitable method of puniſhing all crimes among the Chriſtians or Jews, unleſs it be for the murder of a Turk.

AVANTURINE, in foſſilogy, demonſtrates a ſort of ſtone of ſhining particles in its contextures. Hence the various compoſitions of glaſs and the filings of copper, ſteel and ſilver, in imitation of this curious production of nature; which, when grated, has a pleaſing effect upon writings inſtead of ſand.

AVARAMO Temo, in botany, ſignifies a ſiloquoſe tree, a native of South America, the bark of which is ſaid to be good againſt cancers, and alſo an aſtringent, and powerful in invigorating relaxed parts.

AVARIA, in the Turkiſh polity, indicates the doceur taken by the Mahometan governors as a conciliating fee, when falſe reports are given of the conduct of Chriſtian ſubjects; a mode not unfrequent in the Turkiſh cities of note.

AVAST, in the ſea-language, is a term requiring to ſtop, keep off, or ſtand aloof.

AVAUNCHERS, in the menage, are the ſecond branches of a deer's horns.

AUBAINE, in the cuſtoms of France, is a right veſted in the king as heir to all foreigners that die within his dominions.

By this right the French king is ſole legatee of all foreigners that die within his dominions, notwithſtanding any teſtament the deceaſed can or may make.

An ambaſſador is not ſubject to the right of aubaine; the Swiſs, Savoyards, Iriſh, Scots, and Portugueſe, are alſo exempted, being deemed natives and regnicoles.

AUBIN, in horſemanſhip, ſignifies a broken gait of going between an amble and a gallop, and accounted as a defect.

AUCTION, implies a public ſale, now very much in uſe for diſpoſing of houſehold goods, books, plate, &c.

By this method of ſale the higheſt bidder is always the buyer. This method was originally a kind of ſale among the ancient Romans, performed by the public crier *ſub haſta*, i. e. under a ſpear ſtuck up on that occaſion, by a magiſtrate, who made good the ſale by the delivery of the goods.

AUDEANISM, in eccleſiaſtical hiſtory, is the ſame with anthropomorphiſm, or anthroporphites.

AUDIENCE, in a general ſenſe, implies hearing, or the aſſemblage of perſons who are diſpoſed to hear ſomething to be ſaid or ſpoken.

In polity, it implies a ceremony obſerved in courts on the admiſſion of ambaſſadors or public miniſters to the preſence of a king, &c.

In England, an audience is given to ambaſſadors in the preſence-chamber; to envoys and reſidents, in a gallery, cloſet, or in any place where the king happens to be. Upon being admitted, as is the cuſtom of all courts, they make three bows; after which they cover and ſit down; but not before the king is covered and ſat down, and has given them the ſign to put on their hats. When the monarch does not chuſe to have them covered, and ſit, he himſelf ſtands uncovered; which is taken as diſreſpect.

At Conſtantinople, miniſters uſually have audience of the prime vizier, inſtead of the ſultan.

Audience is alſo the name of a court of juſtice eſtabliſhed in the Weſt-Indies belonging to the Spaniards, anſwering in effect to the parliament of France. Theſe courts comprehend ſeveral provinces, called alſo audiences from the names of the tribunal to which they belong.

Audience is alſo the name of an eccleſiaſtical court held by the archbiſhop of Canterbury, in which differences upon elections, conſecrations, inſtitutions, marriages, &c. are heard and determined.

AUDIENDO & Terminando, in law, is a writ of commiſſion to certain perſons, when an inſurrection or riot is committed in any place, for the appeaſing of the populace, and the puniſhment of the ring leaders.

AUDIENTES, or Auditores, in church hiſtory, were an order of catechumens; conſiſting of thoſe newly inſtructed in the myſteries of the Chriſtian religion, and not yet admitted to baptiſm.

AUDIT, implies a regular hearing and examination of an account by proper officers, appointed for that purpoſe.

AUDITOR, in a general ſenſe, ſignifies a hearer, or one who liſtens or attends to any thing.

Auditor, in law, is an officer of the king, who examines yearly the accounts of the under officers, or clerks, makes up a general book, with the difference between their receipts and charges, and their allowances to allocations.

Auditor *of the Receipts*, in government, is an officer of the exchequer who files the tellers bills, makes an entry of them, and gives the lord treaſurer a certificate of the money received the week before. He alſo makes debentures to every teller, before they receive any money, and takes their accounts. He keeps the black book of receipts, and the treaſurer's key of the treaſury, and ſees every teller's money locked up in the new treaſury.

Auditors *of the Revenue*, or properly ſpeaking, of the exchequer, are officers who take the accounts of thoſe who collect the revenues and taxes raiſed by parliament, and receive the accounts of the ſheriffs, eſcheators, collectors, tenants, and cuſtomers, and ſet them down in a book, and perfect them by diſtinguiſhing their ſeveral amounts.

Auditors *of the Preſt and Impreſt*, were officers of the exchequer, who took and made up the accounts of Ireland, Berwick, the mint, and of any money impreſſed to any man for the king's ſervice. They received poundage on all accounts paſſed by them, which amounted to a prodigious ſum, eſpecially in time of war. But the office is now aboliſhed, and 7000l. a year given to the incumbents.

Auditors *Collegiate, Conventual*, &c. were officers formerly appointed in colleges, &c. to examine and paſs their accounts.

AUDITORIUM, in the ancient churches, was that part of the church where the audientes ſtood to hear and be inſtructed.

The auditorium was that part now called *navis eccleſiæ*. In the primitive times, the church was ſo ſtrict in keeping the people together in that place, that the perſon who went from thence in ſermon time was ordered by the council of Carthage to be excommunicated.

AUDITORY, in a general ſenſe, implies ſomething relating to hearing, whether vocal or inſtrumental.

Auditory, or Audience, ſignifies an aſſembly of people who attend to hear a perſon that ſpeaks in public.

Auditory is alſo uſed for the bench on which a magiſtrate or judge hears cauſes.

Auditory *Paſſage*, in anatomy, is the entrance of the ear.

AVELLANDA, in botany, is a name given to the roots of the tarſi, or ſweet cyprus. It is a native of South America. They are eſculent and highly palateable. This ſpecies ſeems to be a variety of the avellana nux. The Spaniards eſteem theſe roots as ſalutary in many medical preſcriptions.

AVELLANE, in heraldry, a croſs, the quarters of which ſomewhat reſemble a filbert-nut. Sylvanus Morgan ſays, that it is the croſs which enſigns the mound of authority, or the ſovereign's globe.

AVE-MARIA, or Hail Mary, ſignifies the angel Gabriel's ſalutation of the Virgin Mary, when he brought her the tidings of the incarnation. It is become a prayer or form of devotion in the Romiſh church. Their chaplets and roſaries are divided into ſo many ave-marias, and ſo many pater-noſters, to which the Papiſts aſcribe a wonderful efficacy!

AVENA, Oats, in botany, is a genus of the digynia order, belonging to the triandria claſs of plants; and in the natural method ranking under the 4th order, Gramina. The calyx has a double valve, and the awn on the back is contorted.

There are 13 ſpecies, ſix of which are natives of Great Britain: viz.

1. The nuda, or naked oats.
2. The fatua, or bearded oat-graſs.
3. The pratenſis, or meadow oat-graſs.
4. The pubeſcens, or rough oat-graſs.
5. The elatior, or tall oat-graſs.
6. The flaveſcens, or yellow oat-graſs.

It is ſomewhat remarkable, that the native place of the ſativa, or common oats, cultivated in our fields, is totally unknown. Lord Anſon in his Voyage round the World, has obſerved that he ſaw it growing wild or ſpontaneouſly in the iſland of Juan Fernandez.

Oats is an article of the materia medica. Gruels made from it have a kind of ſoft mucilaginous quality: by which they obtund acrimonious humours, and prove uſeful in inflammatory diſeaſes, coughs, hoarſeneſs, and exulcerations of the fauces.

AVENACEOUS, technically implies, ſomething belonging to, or partaking of the nature of oats.

AVENAGE, in law, is a certain quantity of oats paid by a tenant to a landlord, inſtead of rent or ſome other duties.

AVENEA, in the menage, implies the rouſing of the ſlot. Hence, avening, or the buck hounds cry, when in full view of the chace.

AVENII, in ancient hiſtory, ſignify thoſe who publicly offered their ſervices for hire, to perform the gambols of the amphitheatres. They were univerſally held in diſrepute, as profligate and diſſolute; beings unfit for any ſociety but among their own claſs: and who were no better than gladiators.

AVENOR, ſignifies an officer belonging to the king's ſtables, who provides oats for the horſes. He acts by warrant from the maſter of the horſe.

AVENS, in botany, is the ſame as Cariophillus.

AVENTURE, in law, implies a miſchance cauſing the death of a perſon without felony, uſually called chance medley.

AVENUE, in gardening, is a walk planted on each ſide with trees, and leading to an houſe, garden-gate, wood, &c. and generally terminated by ſome diſtant object to form a perſpective view.

AVERA, in law, ſignifies the dooms day books, technical term for the day's work of a ploughman, which the king's tenants in his demeſne lands were obliged to pay to the ſheriff.

AVERAGE, in commerce, ſignifies the accidents and misfortunes which happen to ſhips and their cargoes, from the time of their loading and ſailing, their return and unloading; which may be divided into three kinds, viz.

1. The ſimple average, which conſiſts in the extraordinary expences incurred for the ſhip alone, or for the merchandizes alone. Such is the loſs of anchors, maſts, and rigging, occaſioned by the common accidents at ſea; the damages which happen to merchants by ſtorm, prize, ſhipwreck, wet, or rotting; all which muſt be borne and paid by the thing which ſuffered the damage.

2. The large and common average, being thoſe expences incurred, and damages ſuſtained, for the common good and ſecurity both of the merchandizes and veſſels, conſequently to be borne by the ſhip and cargo, and to be regulated upon the whole. Of this number are the goods or money given for the ranſom of the ſhip and cargo, things thrown overboard for the ſafety of the ſhip, the expences of unloading for entering into a river or harbour, and the proviſions and hire of the ſailors when the ſhip is put under an embargo.

3. The ſmall aver ages, which are the expences for towing and piloting the ſhip out of or into harbours, creeks, or rivers, one third of which muſt be charged to the ſhip, and two thirds to the cargo.

Average, in a more reſtrained ſenſe, implies the contribution that merchants make proportionably to their loſſes, who have had their goods caſt into the ſea in the time of a tempeſt. It alſo ſignifies a ſmall duty which thoſe merchants, who ſend goods in another man's ſhip, pay to the maſter for his care of them over and above the freight. Hence it is expreſſed in the bills of lading, paying ſo much freight for the ſaid goods, with primage and average accuſtomed.

Average, in mercantile tranſactions, denotes the rating of goods which run from low to high numbers in the invoice, and from low to high prices, at ſo much per cent. ſo as to rate the like profits on the ſales of each. This mode is ſcrupulouſly purſued in every great commercial fair throughout Europe.

AVERDUPOIS, is the ſame as Avoirdupois.

AVERIA, in law, indicates a plurality of plough cattle, or horſes for that uſe. As *bos* and *equus* are in the ſingular, of each kind; averia, implies the plural of both.

AVERIIS, *Captis in Withernam*, in law, is a writ, which is allowed to be granted to any one whoſe cattle have been diſtrained wrongfully, ſo as to reimburſe his ſtock, by the cattle of him who has defrauded him of his right.

This writ has no juriſdiction out of the county; in which the tranſaction, in the firſt inſtance took place.

AVERMENT, in law, ſignifies the proofs adduced in bar of exceptions, which are in the courſe of the pleadings propounded, as a legal ſtatement of facts; ſo that in the ſtrict ſenſe of juſtice, the averror ſpeaks according to the dictates of his conſcience.

AVERRHOA, in botany, is a genus of the decandria order, belonging to the pentagynia claſs of plants; and in the natural method ranking under the 14th order, Gruinales. The calyx has five leaves, the petals are five, opening at top; and the apple or fruit is pentagonus, and divided into five cells.

There are three ſpecies, viz. the blimbi, the carambola, and the acida, all natives of the Indies.

The moſt diſtinguiſhed of theſe is the carambola, called in Bengal the *camrue* or *camrunga*, is remarkable for poſſeſſing a power ſomewhat ſimilar to the ſpecies of Mimoſa which are termed *ſenſitive plants*; its leaves, on being touched, moving very perceptibly.

AVERRUNCI Dei, in mythology, certain gods, whoſe buſineſs it was, to avert misfortunes. Apollo and Hercules were of the number of thoſe gods, among the Greeks; and Caſtor and Pollux, among the Romans.

AVERRUNCIATION, in huſbandry, denotes the act of pruning, or lopping off ſuperfluous branches or ſuckers from the ſtock. The word is ſynonymous with pruning of trees.

AVERSION, is one of the human paſſions, that according to Lord Kames, is oppoſed to affection, and not to deſire, as it commonly is. We have an affection to one perſon; and an averſion to another: the former diſpoſes us to do good to its object, the latter to do evil.

AVERTI, in horſemanſhip, is applied to a regular ſtep or motion enjoined in the leſſons.

The word is French, and ſignifies adviſed.

AVERY, ſignifies the royal granary for repoſiting corn, neceſſary for the king's horſes. In a general ſenſe, it implies ſtores of oats.

AVES, *Birds*, is the name of Linnæus's ſecond claſs of animals. But in this work it makes a complete Syſtem, called Ornithology, which is improved into the modern method of claſſification, according to the arrangement of Mr. Latham, of Dartford. The diviſions, orders, genera, ſpecies, varieties and denominated peculiarities are arranged not only in ſyſtematical order, but alſo under each article in the alphabet, which include an individual race of this numerous claſs of feathered animals; ſo that the deſcriminating naturaliſt will find the moſt ſcrupulous attention to ſcientific demonſtration, whether detached or ſyſtematic.

AUGES, in aſtronomy, are two points in the orbit of a planet, uſually called the apogee, and perigee.

AUGITES, in foſſilogy, implies an inferior ſort of rough topaz, not advanced to the clearneſs of its water, and requires time for maturation.

AUGMENTATION, in a general ſenſe, is the act of adding or joining ſomething to another with a deſign of making it more conſiderable.

Augmentation was alſo the name of a court erected 27 Hen. VIII. ſo called from the augmentation of the revenues of the crown, by the ſuppreſſion of religious houſes; and the office ſtill remains, which there are many curious records, though the court has been diſſolved many years.

Augmentation, in heraldry, implies additional charges to a coat-armour, frequently given as particular marks of honour, and generally borne either in the eſcutcheon or a conton; as have all the baronets of England, who have borne the arms of the province of Ulſter in Ireland, which diviſion of that kingdom contains nine counties; ſo that the emblem is of the greateſt degree of honor in the baronetage.

AUGRE, or Awgre, is an inſtrument uſed by carpenters, joiners, and various other mechanics, to bore round holes; it conſiſts of a wooden handle, and an iron blade terminated at bottom with a ſteel bit, in the form of a ſingle ſcrew.

AUGSBURG *Confeſſion*, in eccleſiaſtical hiſtory, denotes a celebrated confeſſion of faith drawn up by Luther and Melancthon, on behalf of themſelves and other antient reformers, and preſented in 1530 to the emperor Charles V. at the diet of Auguſta or Augſburg, in the name of the evangelic body. This confeſſion contains 28 chapters; of which the greateſt part is employed in repreſenting, with perſpicuity and truth, the religious opinions of the proteſtants, and the reſt in pointing out the errors and abuſes that occaſioned their ſeparation from the church of Rome.

AUGSTORY, in naval architecture, ſignifies the quarter deck, or eminence which adjoins the main deck. The word implies the grand loft or higheſt floor from the water's edge.

AUGUR, denoted an officer among the Romans appointed to foretel future events, by the chattering, flight, and feeding of birds. There was a college or community of them, conſiſting originally of three members, who ever afterwards increaſed to nine, four of whom were patricians and five plebeians. They bore an augural ſtaff or wand, as the enſign of their authority; and their dignity was ſo much reſpected, that they were never depoſed, nor any ſubſtituted in their place, though they ſhould be convicted of the moſt enormous crimes.

Augury is a very ancient work of ſuperſtition. We know from Heſiod, that huſbandry was in part regulated by the arrival and migration of birds; and moſt probably it had been in uſe long before his time, as aſtronomy was then in its infancy. In proceſs of time, theſe birds ſeem to have gained great authority, ſo that no affair of conſequence was undertaken without conſulting their motions.

They were looked upon as the interpreters of the gods; and thoſe who were qualified to underſtand their oracles were held among the chief men in the Greek and Roman ſtates, and became the aſſeſſors of kings. However abſurd ſuch an inſtitution as a college of Augurs may appear in our eyes, yet, like all other extravagant inſtitutions, it had in part its origin from nature. When men conſidered the wonderful migration of birds, how they diſappeared at once, and appeared again at ſtated times, and could give no gueſs where they went, it was almoſt natural to ſuppoſe, that they retired ſomewhere out of the ſphere of this earth, where they might converſe with the gods, and thence be enabled to predict events.

It was natural for a ſuperſtitious people to imagine this extravaganza, as ſoon as ſome impoſtor was wicked enough to aſſert it. Added to this, the diſpoſition in ſome birds to imitate the human voice, might contribute much to the confirmation of ſuch a doctrine.

From what has been obſerved, it ſeems probable that natural augury gave riſe to artificial augury, the mind of man making a very eaſy tranſition from a little truth to a great deal of error.

Augury, according to Varro, may be diſtinguiſhed into four parts, viz.

1. Pyromancy,	or, Augury, by	Fire.
2. Hydromancy,		Water.
3. Acromancy,		Air.
4. Geomancy,		Earth.

Each of which formed a doctrine of divination in itſelf, as deſcribed under each Article.

AUGUST, in a general ſenſe, implies ſomething majeſtic, venerable, or ſacred. The appellation was firſt conferred by the Roman ſenate upon Octavius, after his being confirmed by them in the ſovereign power. It was conceived as expreſſing ſomething divine, or elevated above the pitch of mankind.

August, in chronology, is the eighth month of the year, and containing 31 days. It was dedicated to the honour of Auguſtus Cæſar, becauſe, in the ſame month, he was created conſul, thrice triumphed in Rome, ſubdued Egypt to the Roman empire, and made an end of civil wars.

AUGUSTALES, in Roman antiquity, was an epithet given to the flamens or prieſts appointed to ſacrifice to Auguſtus after his deification; and alſo to the ludi or games celebrated in honour of the ſame prince on the fourth of the ides of October.

AUGUSTALIA, was a feſtival inſtituted by the Romans in honour of Auguſtus Cæſar, on his return to Rome, after having ſettled peace in Sicily, Greece, Syria, Aſia, and Parthia; on which occaſion they likewiſe built an altar to him, inſcribed Fortunæ reduci.

AUGUSTALIS Præfectus, was a title peculiar to a Roman magiſtrate, who governed Egypt with a power much like that of a proconſul in other provinces.

AUGUSTEUM Marmor, in mineralogy, ſignifies the two coloured marble uſually denominated Egyptian marble. The term is antique, and is ſynonymous with green and white marble.

AUGUSTUS, was the appellation conferred upon Cæſar Octavianus, the firſt Roman emperor: and implies the ſame as Auguſt.

AVIARY, denotes a place ſet apart for feeding and propagating birds.

AVICENIA, *Eaſtern Anacardium*, in botany, is a genus of the angioſpermia order, belonging to the didynamia claſs of plants; and in the natural method ranking under the 40th order, Perſonatæ.

The calyx is quinquepartite; the corolla is bilabiated, the upper lip ſquared; the capſule is leathery, romb-like, and monoſpermous.

There are two ſpecies; the tomentoſa or downy, and the nitida or ſhining.

AVIGNON Berry, ſignifies the fruit of a ſpecies of lycium; growing plentifully near Avignon and in other parts of France. The berry is ſomewhat leſs than a pea; and of a green colour, approaching towards yellow; it is of an aſtringent quality and bitter taſte.

It is uſed by dyers and painters, who make of it a fine golden yellow.

AVIS, in ornithology; ſignifies a bird; hence the various exotics are ranged under the ſpecies of avis pennipulchra, when they are novel to the naturaliſt.

Nieremberg deſcribes the avis pennipulchra, as a diminutive variety of the peacock genus; and of the ſize of a pigeon; a native of America.

All deſcriptions of the feathered race, which are enumerated under the name of bird, commonly begin with the term avis; as, avis tropicorum; avis paradiſi, &c. tropic bird, bird of paradiſe, &c.

Avis, *or Knights d'Avis*, was an order of knighthood in Portugal, eſtabliſhed about the year 1162.

Hiſtory records the occaſion of their inſtitution to be as follows: when the city of Evora was taken from the Moors, in the reign of the firſt king of Portugal, it was garriſoned by ſeveral perſons, who aſſumed the title of knights of St. Mary of Evora, which was ſoon after changed for that of knights d'Avis, which the king gave them, and whither they removed from Evora.

The badge of the order is a green croſs flory; in diſcipline they obſerve the rule of St. Benedict.

Avis Longa, in ornithology, is a running bird, common in the Carolinas. Latham deſcribes it as partaking of the vulture genus. Neiremberg ſuppoſes it to be of the falcon ſpecies, and degenerated variety.

AVISI, in the menage, indicates a flock of game, ſo formed in their haunt, as to give the ſportſman an opportunity of diſcharging his fowling piece to advantage.

AVISIE, in muſic, denotes a band of wind inſtruments belonging to the military department; contradiſtinguiſhed from arriſery or ſtringed inſtruments.

AVISO, is a term in commerce, which denotes an advertiſement, an advice, or of intelligence of any kind.

AULA *Regia*, or *Regis*, was a court eſtabliſhed by William the conqueror in his own hall, compoſed of the great officers of ſtate, who reſided in his palace, and were uſually attended on his perſon.

This court was regulated by the article which forms the eleventh chapter of Magna Charta, and eſtabliſhed in Weſtminſter-hall, where it has ever ſince continued.

AULETES, in antiquity, denotes a flute-player.

AULIC, is an epithet given to certain officers of the German empire, who compoſe a court which decides, without appeal, in all ceſſes entered in it. Thus we ſay, aulic council, aulic chamber, aulic counſellor.

The aulic council is compoſed of a preſident, who is a Catholic; of a vice chancellor, preſented by the archbiſhop of Mentz; and of 18 counſellers, nine of whom are proteſtants and nine catholics. They are divided into a bench of lawyers, and always follow the emperor's court; for which reaſon they are called juſtitium imperatoris, the emperor's juſtice, and aulic council.

The aulic court ceaſes at the death of the emperor; whereas the imperial chamber of ſpire is perpetual, repreſenting not only the deceaſed emperor, but the whole Germanic body, which is reputed never to die.

Aulic *Doctrine*, in the Sorbonne and foreign univerſities, implies an act which a young divine maintains upon being admitted to the degree of a doctor of divinity.

It begins by an harangue of the chancellor, addreſſed to the young doctor, after which he receives the cap, and precides at the aulic, or diſputation, to confirm his doctrine.

AULOS, in ichthyology, ſignifies a variety of the ſpecies ſolen, or ſword fiſh.

Aulos ſignifies a Grecian long meaſure, the ſame with ſtadium; uſual in the ſurveys of Atica.

AUMBRY, a provincial word denoting a cup-board.

AUME, ſignifies a Dutch meaſure for Rheniſh wine, containing 40 Engliſh gallons.

AUMONE, in church government, ſignifies the ſums that are collected at places of divine worſhip, for the benefit of the poor of the pariſh, and diſtributed at Eaſter and Chriſtmas.

AUNCEL *Weight*, in many parts of England, ſignifies meat ſold by the hand, without weighing.

AUNE, is a long meaſure uſed in France to meaſure cloths, ſtuffs, ribbons, &c.

AVOCATORIA, is a mandate of the emperor of Germany, addreſſed to ſome prince, in order to ſtop his unlawful proceedings in any cauſe, appealed to him.

AVOIDANCE, in the canon law, is underſtood when a benefice becomes void of an incumbent; which happens either in fact, by the death of the perſon; or in law, by ceſſion, deprivation, reſignation, &c.

In the firſt of theſe caſes, the patron muſt take notice of the avoidance at his peril; but in avoidance by law, the ordinary is obliged to give notice to the patron, in order to prevent a lapſe.

AVORDUPOIS *Weight*, in merchandize, is uſed for the larger and coarſer commodities, ſuch as groceries, cheeſe, wool, lead, &c.

Bakers, who do not live in corporation towns, are to make their bread by avoirdupois weight, but thoſe in corporations by troy weight.

Apothecaries buy by avoirdupois weight, but ſell by troy weight. The proportion of a pound avoirdupois to a pound troy is as 17 to 14.

AVOWEE, in civil law, implies a perſon who has a right to preſent to a benefice. He is thus called in contradiſtinction to thoſe who only have the lands to which the advowſon belongs for a term of years, or by virtue of intruſion or diſſeiſin.

AVOWRY, in law, is to be underſtood where a perſon diſtrained ſues out a replevin; for then the diſtrainer muſt vow, and juſtify his plea, which is called his avowry.

AURA, among phyſiologiſts, indicates an airy exhalation, or vapour.

Aura, in ornithology, is a ſynonymous term with that of vulture.

Aura, in chemiſtry, implies the ſublimate ſpirit contained both in the animal and vegetable kingdoms of nature. In the materia medica, it denotes a ſpecies of remedies which are taken as noſtrums for all impurities of the blood.

AURELIA, in natural hiſtory, is the ſame with what is more uſually called chryſalis, and ſometimes nymph. But it is defined under the former.

AURELIANA, in botany, is a ſynonyme of the panax and ginſeng.

AUREOLA, in its original ſignification, ſignifies a jewel, which is propoſed as a reward of victory in ſome public diſpute. Hence the Roman ſchoolmen applied it to denote the reward beſtowed on martyrs, virgins, and doctors, on account of their works of ſupererogation; and painters uſe it to ſignify the crown of glory with which they adorn the heads of ſaints, confeſſors, &c.

AUREUS, was a Roman gold coin, equal in value to 25 denarii. According to Ainſworth, the aureus of the higher empire weighed near five pennyweights; and in the lower empire, little more than half that weight.

We learn from Suetonius, that it was cuſtomary to give aurei to the victors in the chariot races.

AURICLE, in anatomy, ſignifies that part of the ear which is prominent from the head, called by many authors auris externa.

AURICLES are likewiſe two muſcular bags ſituated at the baſis of the heart, and intended as diverticula for the blood during the diaſtole.

AURICULA, in botany, is the ſame as Primula.

Auricula, in entomology, ſignifies the ſame as that well known inſect, called the ear-wig.

AURICULAR, in a general ſenſe, implies ſomething relative to the ear, or organs of hearing: hence,

Auricular *Confeſſion*, private confeſſion.

Auricular *Witneſs*, an ear witneſs.

Auricular *Report*, an hearſay rumour.

Auricular *Medicines*, ſuch as are ſuited to cure the diſtempers of the ear.

AURICULATED *Leaf*, in botany, ſignifies that which has a lobe on each ſide towards the baſe.

AURIFLAMMA, in the French hiſtory, properly denotes a flag or ſtandard belonging to the abbey of St. Dennis, ſuſpended over the tumb of that ſaint, which the religious orders in an occaſion of war in defence of their lands or rights, took down, with great ceremony, and gave it to their protector or advocate, to be borne at the head of their forces.

Auriflamma is alſo ſometimes uſed to denote the chief flag or ſtandard in any army.

AURIGA, *the Waggoner*, in aſtronomy, ſignifies a conſtellation of the northern hemiſphere, conſiſting of 23 ſtars, according to Tycho Brahe; 40, according to Hevelius; and 68, in the Britannic catalogue.

AURIGRAPHUS, in hiſtory, denotes a calligrapher, or one who recorded tranſactions in gold letters.

The word is compounded of *aurum*, gold, and γραφω, I write.

AURIPIGMENTUM, *Orpiment*, in natural hiſtory, is defined under the article Orpiment.

AURISCALPIUM, in ſurgery, is an inſtrument to clean the ears, and ſerving alſo for other operations in diſorders of thoſe parts.

AURORA, ſignifies the morning twilight, or that faint light which appears in the morning when the ſun is within 18 degrees of the horizon.

Aurora, in mythology, implied the goddeſs of the morning. It was under this name that the ancients deified the light which foreruns the riſing of the ſun above our hemiſphere.

Aurora Borealis, ſignifies the northern twilight, or ſtreamers; a kind of meteor appearing in the northern part of the heavens, moſtly in the winter-time, and in froſty weather. In the arctic regions it appears in perfection, during the ſolſtice.

In the Schetland iſlands, (the merry dancers, as they are there called,) are the conſtant attendants of clear evenings, and prove great reliefs amidſt the gloom of the long winter nights. They commonly appear at twilight near the horizon, of a dun colour, approaching to yellow; ſometimes continuing in that ſtate for ſeveral hours without any ſenſible motion; after which they break out into ſtreams of ſtronger light, ſpreading into columns, and altering ſlowly into ten thouſand different ſhapes, varying their colours from all the tints of yellow to the obſcureſt ruſſet. They often cover the whole hemiſphere, and then make the moſt brilliant appearance. Their motions at theſe times are amazingly quick; and they aſtoniſh the ſpectator with the rapid change of their form. They break out in places where none were ſeen before, ſkimming briſkly acroſs the ſky, and are ſuddenly extinguiſhed, and leave behind an uniform duſky track. This again is brilliantly illuminated in the ſame manner, and as ſuddenly left a dull blank.

In certain nights they aſſume the appearance of vaſt columns, on one ſide of the deepeſt yellow, on the other declining away till it becomes undiſtinguiſhed from the ſky. They have generally a ſtrong tremulous motion from end to end, which continues till the whole vaniſhes. In a word, we who only ſee the extremities of theſe northern phænomena, have but a faint idea of their ſplendor and their motions.

According to the ſtate of the atmoſphere, they differ in colours, and their appearance terrifies the ruſtic ſpectators with the dread of war, peſtilence, and famine.

AUSCULTARE, in eccleſiaſtical hiſtory, denotes the muſical moderator, or liſtener, who taught the monks the pitch of voice, to ſing and chant in cathedrals and other churches.

AUSI, in hiſtory, were an ancient ſavage people of Libya.

They celebrated annually a feaſt in honour of Minerva, in which the girls divided into two companies, fought with ſticks, and thoſe who died of their wounds were concluded not to have been virgins.

AUSPEX, was a title originally given to thoſe who were afterwards denominated augurs.

AUSTERE, ſignifies rough, aſtringent. Thus an auſtere taſte is ſuch a one as conſtringes the mouth and tongue; as that of unripe fruits, harſh wines, &c.

AUSTERITY, in morality, implies ſeverity and rigour.

AUSTRAL, **Australis**, ſignifies the ſame as ſouthern. Thus auſtral ſigns are the ſix laſt ſigns of the zodiac; ſo called becauſe they are on the ſouth ſide of the equinoctial line.

AUSTRALIS Piscis, the Southern fiſh, in aſtronomy is a conſtellation of the ſouthern hemiſphere, not viſible in our latitude; whoſe ſtars in Ptolemy's catalogue are 18, and in the Britannic catalogue 24.

AUSTROMANCY, **Austromantia**, properly denotes ſoothſaying, or a vain method of predicting futurity, from obſervations of the winds.

AUTER Vie, in law, ſignifies a tenant for life, dependant on the demiſe of the grantor.

Auter *Droit*, in law, denotes a ſuit inſtituted in the right of another's perſon, as executor, adminiſtrator, &c.

AUTHENTICATING, in civil law, was the ancient form of publicly whipping an adultreſs: then if her huſband was not reconciled ſhe was confined for two years in a convent, at the expiration of which period, ſhe was again offered, and if then refuſed, was afterwards confined for life.

AUTHENTIC, denotes ſomething of acknowledged and received authority. In law, it ſignifies ſomething clothed in all its formalities, and atteſted by perſons to whom credit has been regularly given. Thus we ſay, authentic papers, authentic inſtruments, authentic intelligence.

AUTHOR, properly ſignifies one who created or produced any thing. Thus God, by way of eminence, is called the author of Nature, the author of the Univerſe.

Author, in matters of literature, ſignifies a perſon who has compoſed ſome book or writing.

AUTHORITY, in a general ſenſe, denotes a right to command. In which ſenſe, we ſay, the royal authority, the epiſcopal authority, the authority of a father, &c.

It denotes alſo the teſtimony of an author of eminence, quoted in a diſcourſe by way of proof of the facts ſtated by another.

Authority is repreſented, in painting, like a grave matron ſitting in a chair of ſtate, richly clothed in a garment embroidered with gold, holding in her right-hand a ſword, and in her left a ſceptre. By her ſide is a double trophy of books and arms.

AUTOCHTHONES, is an appellation aſſumed by ſome nations, importing that they ſprung, or were produced, from the ſame ſoil which they ſtill inhabited. In this ſenſe, Autochthones amounts to the ſame with Aborigines.

The proper Autochthones were thoſe primitive men who had no other parent beſide the earth. But the name was alſo aſſumed by the deſcendents of theſe men, provided they never changed their ancient ſeat, nor ſuffered other nations to mix with them. In this ſenſe it was that the Greeks, and eſpecially the Athenians, pretended to be Autochthones; and, as a badge thereof, wore a golden graſshopper woven in their hair, an inſect ſuppoſed to have the ſame origin.

AUTOCRATOR, in hiſtory, was a perſon veſted with an abſolute independent power, by which he was rendered unaccountable to any other for his actions.

AUTO Da fe, ſignifies the act of faith.

AUTODIDACTUS, ſignifies a perſon ſelf-taught, or who has had no maſter, or aſſiſtant of his ſtudies, beſides himſelf.

AUTOGRAPH, denotes a perſon's hand-writing, or the original manuſcript of any book, &c.

AUTOCEPHALUS, in eccleſiaſtical hiſtory, were ſuch of the biſhops as acknowledged no ſuperior. In a general ſenſe, it implies a perſon who has no maſter, but is ſolely his own director and governor.

AUTOMATON, in mechanics, indicates a ſelf-moving machine, conſtructed ſo as to move for a conſiderable time, as though endued with animal life. According to this deſcription, clocks, watches, and all machines of that kind, are automata.

M. Le Droz of La Chaux de Fonds in the county of Neufchattel, hath executed ſome very curious pieces of mechaniſm, which well deſerve to be ranked high in the liſt of Automata. One was a clock, which was preſented to the king of Spain; and had, among other curioſities, a ſheep, which imitated the bleating of a natural one; and a dog watching a baſket of fruit: when any one attempted to purloin the fruit, the dog gnaſhed his teeth and barked; and if it was actually taken away, he never ceaſed barking till it was reſtored. Beſides this, he made a variety of human figures, which exhibited motions truly ſurpriſing; but all inferior to Mr. Kempell's cheſs-player, which is deſcribed under the article Androides, and which may juſtly be looked upon as the greateſt maſter-piece in mechanics ever invented.

AUTONOMIA, in polity, is a power of living or being governed by our own laws and magiſtrates. The liberty of the cities which lived under the faith and protection of the Romans, conſiſted in their autonomia, i. e. they were allowed to make their own laws, and elect their own magiſtrates; by whom juſtice was to be adminiſtered, and not by Roman preſidents or judges, as was done in other places which were not indulged with the autonomia.

AUTOPSY, in oratory, ſignifies ocular demonſtration; i. e. are eye witneſs of the tranſaction in queſtion.

AUTOUR, in dyeing, ſignifies a ſort of bark imported from the Levant, well known in commercial entries, as a carmine dye ſtuff.

AUTUMN, ſignifies the third ſeaſon of the year, when the harveſt and fruits are gathered in.

Autumn is repreſented, in painting, by a man at perfect age, clothed like the vernal, and likewiſe girded with a ſtarry girdle; holding in one hand a pair of ſcales equally poiſed, with a globe in each: in the other hand, a bunch of divers fruit and grapes. His age denotes the perfection of this ſeaſon; and the balance, that ſign of the zodiac which the ſun enters when our autumn begins.

It commences on the day that the ſun's meridian diſtance from the zenith begins to decreaſe, and is a mean between the greateſt and the leaſt; which in theſe countries is ſuppoſed to happen when the ſun enters Libra.

Several nations have computed the years by autumns; as the Engliſh Saxons did by winters.

AUTUMNAL Point denotes that part of the equinox from which the ſun begins to deſcend towards the ſouth pole.

Autumnal *Signs*, in aſtronomy, are the three ſigns Libra, Scorpio, and Sagittarius, through which the ſun paſſes during the autumn.

Autumnal *Equinox*, ſignifies the time in which the ſun enters the autumnal point.

AUVERNAS, in commerce, is a very deep-coloured heady wine, made of black raiſins ſo called, which comes from Orleans. It is not fit to drink until it is above a year old; but if kept two or three years, it becomes excellent.

AUX, in aſtronomy, ſignifies the arc of the ecliptic intercepted between the firſt point of Aries, and the point in which the ſun or any other planet is, at its greateſt diſtance from the earth.

AUXESIS, in rhetoric, is a figure by which any thing is magnified too much, and is ſyhonymous with hyperbole.

AUXILIARY, in morality and law, ſignifies whatever is aiding or helping to another.

Auxiliary *Verbs*, in grammar, are ſuch as help to form or conjugate others; that is, ſuch as are prefixed to them, to form or denote the moods or tenſes: as, *to have* and *to be*, in the Engliſh; *etre* and *avoir*, in the French; *ho* and *ſono* in the Italian, &c. In the Engliſh language, the auxiliary verb *am* ſupplies the want of paſſive verbs.

AWAIT, in crown law, denotes to way-lay, or take a perſon by ſurprize ſo as to put him in bodily fear, or deprive him of his goods, chattels, or life. By ſtat. 13. R. 2. c. 1. This offence is capital, without benefit of clergy.

AWARD, in law, is the judgment of an arbitrator, or of one who is not appointed by the law a judge, but choſen by the parties themſelves for terminating their difference.

AWEIGH, in tactics, ſignifies the ſame with the ſea phraſe, a trip.

AWL is an inſtrument which ſhoe-makers uſe to bore holes through the leather, to facilitate the ſtitching or ſewing of ſhoes and boots.

AWME, or Aume, is a Dutch liquid meaſure containing eight ſteckans, or 20 verges or verteels, equal to the tierce in England.

AWN, in botany, is the ſame as the Arista.

AWNING, in the ſea-language, ſignifies the hanging of a ſail, tarpawling, or the like, over any part of the ſhip, to ſhade off the ſun, rain or wind.

AX, is a carpenter's inſtrument, ſerving to hew wood. The ax differs from the joiner's hatchet, being made larger and heavier, ſerving to hew large ſtuff; and its edge tapering into the middle of its blade. It is furniſhed with a long handle or helve, as being to be uſed with both hands in felling timber.

Battle-Ax, deſcribed under Celt.

AXAYACATL, is the name of a ſpecies of fly, common in Mexico, about the Lake; the eggs of which being depoſited in immenſe quantities, upon the ruſhes and corn-flags, from large maſſes, which are taken up by fiſhermen and carried to market for ſale. This caviare, called *ahuauhtli*, which has much the ſame taſte with the caviare of fiſh, uſed to be eat by the Mexicana, and is now a common diſh among the Spaniards. The Mexicans eat not only the eggs, but the flies themſelves, made up together in a maſs, and prepared with ſaltpetre.

AXILLA, in anatomy, denotes the arm-pit, or the cavity under the upper part of the arm.

Axilla, in botany, is the ſpace comprehended between the ſtems of plants and their leaves. Hence we ſay thoſe flowers grow in the axillæ of the leaves; i. e. at the baſe of the leaves, or juſt within the angle of their pedicles.

AXILLARY, implies ſomething belonging to or lying near the axilla. Thus, axillary artery is that part of the ſubclavian branches of the aſcending trunk of the aorta which paſſes under the arm-pits; axillary glands are ſituated under the arm-pits, enveloped in fat, and lie cloſe by the axillary veſſels; and axillary vein is one of the ſubclavians which paſſes under the arm-pit, dividing itſelf into ſeveral branches, which are ſpread over the arm.

AXINOMANCY, Axinomantia, from αξινη, *ſecuris*, and μαντεια, *divinatio*; was an ancient ſpecies of divination, or method of foretelling future events by means of an ax or hatchet. This diabolical art was in conſiderable repute among the ancients; and was performed by laying an agate ſtone on a red hot hatchet; or fixing a hatchet on a round ſtake ſo as to be exactly poiſed; then the names of thoſe that were ſuſpected were repeated, and he at whoſe name the hatchet moved was pronounced guilty.

AXIOM, Axioma, in a general ſenſe, comprehends a ſelf-evident truth, or propoſition whoſe truth every perſon receives at firſt ſight. It may alſo be defined an eſtabliſhed principle in ſome art or ſcience. Thus, it is an axiom in phyſics, that nature does nothing in vain; that effects are proportional to their cauſes, c&.

In geometry, it ſignifies, that things equal to the ſame third are alſo equal to one another; that if to equal things are added equals, the ſums will be equal, &c.

In optics, it ſignifies, that the angle of incidence is equal to the angle of reflection, &c.

AXIOSIS, in rhetoric, comprehends the third of an exordium to a diſcourſe. It is uſually made an introductory explanation of the mode and form; and the inient and deſign of the buſineſs in hand.

AXIS, in geometry, is the ſtraight line in a plain figure, about which it revolves, to produce or generate a ſolid. Thus, if a ſemicircle be moved round its diameter at reſt, it will generate a ſphere, the axis of which is that diameter.

Axis, in aſtronomy, is an imaginary right line, ſuppoſed to paſs through the centre of the earth and the heavenly bodies, about which they perform their diurnal revolutions.

Axis, in conic ſections, is a right line dividing the ſection into two equal parts and cutting all its ordinates at right angles.

Axis, in mechanics, may be defined thus:

1. The axis of a balance is that line about which it moves, or rather turns about.

2. Axis of oſcillation is a right line parallel to the horizon, paſſing through the centre about which a pendulum vibrates.

Axis *in Peritrochio*, is one of the ſix mechanical powers, conſiſting of a peritrochium or wheel concentric with the baſe of a cylinder, and moveable together with it about its axis.

Axis, in optics, is that particular ray of light coming from any object which falls perpendicularly on the eye.

Axis, in architecture, may be thus defined:

1. Spiral axis, is the axis of a twiſted column drawn ſpirally, in order to trace the circumvolution without.

2. Axis of the Ionic capital, is a line paſſing perpendicularly through the middle of the eye of the volute.

Axis *of a Veſſel*, is an imaginary right line paſſing through the middle of it, perpendicularly to its baſe, and equally diſtant from its ſides.

Axis, in botany, is a taper column placed in the centre of ſome flowers or catkins, about which the other parts are diſpoſed.

Axis, in anatomy, is the name of the ſecond vertebra of the neck; it hath a tooth which goes into the firſt vertebra, and this tooth is by ſome called the axis.

AXLETREE, in mechanics, is the ſame as axis.

AXOLOTI, in ichthyology, is a moſt ſingular fiſh found in the lake of Mexico; it has feet like a lizard, a matrix like a woman, and is ſubject to a menſtrual diſcharge. It is eſteemed good and wholeſome food, notwithſtanding its irregular order in nature.

AXUNGIA, in a general ſenſe, denotes old lard, or the drieſt and hardeſt of any fat in the bodies of animals: but more properly in medical preſcriptions, it ſignifies only hog's lard.

Axungia *Vitri*, *Sandiver*, or *Salt of Glaſs*, is a kind of ſalt which ſeparates from the glaſs, while it is in fuſion. It is of an acrimonious and biting taſte.

Farriers uſe it for cleanſing the eyes of horſes. It is alſo made uſe of for cleanſing the teeth; and it is ſometimes applied to running ulcers, the herpes, or the itch, by way of deſiccative.

AXYRIS, in botany, is a genus of the triandria order, belonging to the monœcia claſs of plants; and in the natural method ranking under the 12th order, Holoraceæ.

The calyx of the male is tripartite; it has no corolla. The calyx of the female conſiſts of two leaves; it has two ſtyli and one ſeed.

There are four ſpecies none of which are natives of Great Britain.

AYEL, in law, is a writ to reinſtate the heir at law to his demeſne, of which is legally ſeized in fee, of which he has been diſpoſſeſſed by fraud or other illegal means.

AYENIA, in botany, is a genus of the pentandria order, belonging to the gynandria claſs of plants; and in the natural method ranking under the 37th order, Columniferæ.

The calyx has two leaves; the petals are in the form of a ſtar, with long ungues; and the capſule has five cells.

There are three ſpecies, all natives of the Weſt Indies.

AYGULA, in the claſs of Mammalia, and order of Primates, and genus Simia, denotes an American variety of the ape of the larger ſpecies.

AYTONIA, in botany, is a genus of the monodelphia order, belonging to pentandria claſs of plants.

The calyx is quinquepartite; the corolla conſiſts of four petals; the berry is dry, quadrangular, unilocular, and many-ſeeded.

There is but one ſpecies, the capenſis, a native of the Cape of Good Hope.

AZAB, in the Turkiſh armies, denotes a diſtinct body of ſoldiery, who are great rivals of the Janizaries.

AZABE Kaberi, in the Mahometan bible or alcoran, ſignifies the purgatory of thoſe believers, who after a ſlight trial by fire, are made quite pure, and received by Mahomet into Paradiſe.

AZALEA, American Upright Honeysuckle, in botany, is a genus of the monogynia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 18th order, Bicornes,

The corolla is bell-ſhaped; the ſtamina inſerted in the receptacle; and the capſule has five cells.

There are ſix ſpecies, of which the moſt remarkable are:

1. The viſcoſa, with a white flower, is a low ſhrub, ariſing with ſeveral ſtems to the height of two or three feet. The leaves come out in cluſters without any order. The flowers are in cluſters between leaves, and have much the appearance and ſcent of honeyſuckle.

2. The nudiflora, or red American upright honeyſuckle, grows taller than the firſt; and in its native country will ſometimes arrive at the height of 12 feet.

Theſe two ſpecies require a moiſt ſoil and a ſandy ſituation, and can only be propagated from ſlips, as they never produce good ſeeds in England. The autumn is the beſt time to remove the plants, and their roots ought to be covered in winter. They are moſt beautiful plants, and well worth cultivating.

AZARAM, or AZARUM, in farriery, denotes a root much in uſe by the French farriers, for the cure of the farcy in horſes.

AZED, in medicine, is a ſynonymous term for camphor.

AZERECAH, is a ſect of muſſulmen, who deny any place of puniſhment for the ſouls of deceaſed perſons.

AZELFOGE, in aſtronomy, is a fixed ſtar of the ſecond magnitude, in the Saxon's tail.

AZIMUTH, in aſtronomy, is an arch of the horizon, intercepted between the meridian of the place and the azimuth, or vertical circle paſſing through the centre of the object, which is equal to the angle of the zenith, formed by the meridian and virtical circle: or it is found by this proportion, as the radius is to the tangent of the latitude of the place, ſo is the tangent of the ſun's or ſtar's altitude; for inſtance, to the coſine of the azimuth from the ſouth, at the time of the equinox.

Magnetical AZIMUTH, is an arch of the horizon intercepted between the azimuth, or virticle circle, paſſing through the centre of any heavenly body, and the magnetical meridian. This is found by obſerving the object with an azimuth compaſs.

AZIMUTH *Compaſs*, is an inſtrument for finding either the magnetical azimuth or amplitude of an heavenly object.

Dr. Knight has invented an accurate ſea compaſs, which is now uſed in the navy; this inſtrument, with the following contrivance added by the ingenious Mr. Smeaton, anſwers the purpoſes of an azimuth and amplitude compaſs.

The cover of the wooden box being taken off, the compaſs is in a condition to be made uſe of in the binnacle, when the weather is moderate: but if the ſea runs high, as the inner box is hung very free upon its centre, it will be neceſſary to ſlacken the milled nut, placed upon one of the axes that ſupport the ring, and to lighten the nut on the outſide that correſponds to it. By this means the inner box and ring will be lifted up from the edges, upon which they reſt, when free; and the friction will be increaſed, and that to any degree neceſſary, to prevent the too great vibrations, which otherwiſe would be occaſioned by the motion of the ſhip.

To make the compaſs uſeful in taking the magnetic azimuth or amplitude of the ſun and ſtars, as alſo the bearings of headlands, ſhips, and other objects at a diſtance, the braſs edge, deſigned at firſt to ſupport the card, and throw the weight of it as near the circumference as poſſible, is itſelf divided into degrees and halves; which may be eaſily eſtimated into ſmaller parts, if neceſſary. The diviſions are determined by means of a catgut line, ſtretched perpendicularly with the box, as near the braſs edge as may be, ſo that the parallax, ariſing from a different poſition of the obſerver, may be as little as poſſible.

Underneath the card are two ſmall weights, ſliding on two wires, placed at right angles to each other; which being moved nearer to, or farther from, the centre, counterbalance the dipping of the card in different latitudes, or reſtore the equilibrium of it, where it happens by any other means to be got too much out of level.

There is alſo added an index at the top of the inner box, which may be put on and taken off at pleaſure: and ſerves for all altitudes of the object. It conſiſts of a bar, equal in length to the diameter of the inner box, each end being furniſhed with a perpendicular ſtile, with a ſlit parallel to the ſides thereof: one of the ſlits is narrow. to which the eye is applied; and the other is wider, with a ſmall catgut ſtretched up the middle of it, and from thence continued horizontally from the top of one ſtile to the top of the other. There is alſo a line drawn along the upper ſurface of the bar. Theſe four, viz. the narrow ſlit, the horizontal cat-gut thread, the perpendicular one, and the line on the bar, are in the ſame plane, which diſpoſes itſelf perpendicular to the horizon, when the inner box is at reſt, and hangs free. This index does not move round, but is always placed on, ſo as to anſwer the ſame ſide of the box.

When the ſun's azimuth is deſired, and his rays are ſtrong enough to caſt a ſhadow, turn about the wooden box, till the ſhadow of the horizontal thread, or till that of the perpendicular thread, in one ſtile, or the light through the ſlit on the other, falls upon the line in the index bar, or vibrates to an equal diſtance on each ſide of it, gently touching the box, if it vibrates too far: obſerve, at the ſame time, the degree for the azimuth, or any other angle that is reckoned from the meridian, make uſe of the outward circle of figures upon the braſs edge; and the ſituation of the index bar, with regard to the card and needle, will always direct upon what quarter of the compaſs the object is placed.

But if the ſun does not ſhine out ſufficiently ſtrong, place the eye behind the narrow ſlit in one of the ſtiles, and turn the wooden box about, till ſome part of the horizontal or perpendicular thread appears to interſect the centre of the ſun, or vibrate to an equal diſtance on each ſide of it, uſing ſmoked glaſs next the eye. if the ſun's light is too ſtrong.

In this method, another obſerver will be generally neceſſary, to note the degree cut by the nonius, at the ſame time that the firſt gives notice that the thread appears to ſplit the object.

The azimuth of the ſtars may alſo be obſerved by night; a proper light ſerving equally for one obſerver to ſee the thread, and the other the degree upon the card.

AZOGA SHIPS, are thoſe Spaniſh ſhips commonly called the quickſilver ſhips, from their carrying quickſilver to the Spaniſh Weſt Indies, in order to extract the ſilver out of the mines of Mexico and Peru. Theſe ſhips, ſtrictly ſpeaking, are not to carry any goods unleſs for the king of Spain's account.

AZURE, in a general ſenſe, implies the blue colour of the ſky.

AZURE, among paniters, is a term which ſignifies in general a fine blue colour, and was formerly appropriated to Lapis Lazuli, called azure ſtone, and to the blue prepared from it. But ſince a blue has been extracted from Cobalt, cuſtom has applied to it the name of azure, although it differs conſiderably from the former, and is incapable of being uſed for the ſame purpoſes, and particularly for painting in oil.

The former at preſent is called lapis lazuli; or only lapis; and the blue prepared from it for painting in oil, is called ultramarine. The name azure is generally applied to the blue glaſs made from the earth of cubalt and vitrifiable matters. This glaſs, which is called ſmalt when in maſſes, is called azure only when it is reduced to a fine powder.

Several kinds of azure are diſtinguiſhed, according to their degrees of beauty, by the names of fine azure, powdered azure, and azure of four fires. But generally the more intenſe the colour, and the finer the powder, the more beautiful and high priced it is.

AZURE is employed to colour ſtarch; hence it has alſo been called ſtarch blue. It is uſed for painting with colours, and for a blue enamel.

AZURE, in heraldry, ſignifies the blue colour in the arms of any perſon below the rank of a baron. In the eſcutcheon of a nobleman, it is called ſapphire; and in that of a ſovereign prince, Jupiter.

In engraving, this colour is expreſſed by lines or ſtrokes drawn horizontally. It alſo ſignifies juſtice, perſeverance, and vigilance; but according to Mr. Leigh, if it is compounded with

Or	it ſignifies	Chearfulneſs.
Arg.		Vigilance.
Gul.		Readineſs.
Ver.		Enterpriſe.
Pur.		Goodneſs.
Sab.		Mournfulneſs.

The French herald, M. Upton, and his followers, rank this colour before gules.

AZYGOS, in anatomy, is a vein riſing within the thorax, on the right ſide, having no fellow on the left; whence it is called azygos, or vena ſine patri.

AZYMITES, in church hiſtory, were Chriſtians who adminiſtered the euchariſt with unleavened bread.

AZYMOUS, or AZYMUS, ſignifies ſomething unfermented, or made without leaven; as unleavened bread.

Sea-biſket is of this kind; and therefore, according to Galen, leſs wholeſome than bread that has been fermented.

Previous to the commencement of the letter B, *I think it neceſſary to remark to my numerous ſubſcribers, that the letter* A *could not, with any propriety, be brought into a leſs compaſs; and for theſe reaſons: Firſt, this Letter contains more Articles than any other in the Alphabet. And ſecondly, the number of Syſtems we have introduced, ſuch as Acouſtics, Aerology, Aeroſtation, Agriculture, Algebra, Anatomy, Annuities, Architecture, Arithmetic, and Aſtronomy, occupy at leaſt half the quantity of the letter* A. *But this circumſtance cannot again occur under any future Letter, as none contains more than* four, *and, upon an average, not more than* three Syſtems *throughout the remaining part of the Work, ſo that no unneceſſary curtail need be made to give room for them. It is therefore, for theſe reaſons, evident that we have not exceeded thoſe bounds to which our work is limited. Had we brought the letter* A *into a proportionate quantity with the reſt of the alphabet, we muſt have omitted ſome Syſtems, and contracted others. This would have been a material injury to the Work, eſpecially when it is conſidered that thoſe Syſtems are not, as in other Dictionaries, the compilation of an individual, but the real production of men of practical knowledge in the reſpective branches they have undertaken, and whoſe ſignatures and addreſſes are thereto affixed. I muſt alſo add, that I ſhall be particularly attentive to engage Gentlemen of the firſt abilities to execute the ſubſequent Syſtems, by which means I flatter myſelf it will form the moſt complete* Circle of Science *that can poſſibly be collected within the ſame compaſs, and juſtly be conſidered a valuable addition to Engliſh literature.*

With reſpect to the Plates in future, they ſhall be no leſs cautiouſly choſen than the former, as all the ſubjects ſhall, previous to their being engraved, undergo the inſpection of men particularly acquainted with that branch of knowledge to which each Plate will refer. It is my fixed determination they ſhall exceed any ſet of Plates that ever appeared in Europe, both with reſpect to novelty, abundant quantity of matter, judicious ſelection and arrangement, accuracy of drawing, and beauty of Engraving.

C. COOKE.

B

THE letter B is the ſecond not only of the Engliſh but of moſt other alphabets. It is the firſt conſonant, and firſt mute, which in its firſt pronunciation is ſuppoſed to reſemble the bleating of a ſheep; upon which account Pierius tells us in his hieroglyphics, that the Egyptians repreſented the ſound of this letter by the figure of that animal. It is alſo one of thoſe letters which the Eaſtern grammarians call labial, becauſe the principal organs employed in its pronunciation are the lips. It is pronounced by preſſing the whole length of them together, and forcing them open with a ſtrong breath.

It has a near affinity with the other labials P and V, and is often uſed for P both by the Armenians and other Orientals, as in Betrus for Petrus, apſens for abſens, &c.; and by the Romans for V, as in amabit for amavit, berna for verna, &c. whence aroſe that jeſt of Aurelian on the emperor Bonoſus, *Non ut vivat natus eſt, ſed ut bibat*.

Plutarch obſerves, that the Macedonians changed Φ into B, and pronounced Bilip, Berenice, &c. for Philip, Pherenice, &c.; and thoſe of Delphos uſed B inſtead of Π, as βαθεῖν for πυθειν, βικρον for πικρον, &c. The Latins ſaid *ſuppono*, *oppono*, for *ſubpono*, *obpono*; and pronounced *optinuit*, though they wrote *obtinuit*, as Quintilian has obſerved. They alſo uſed B for F or PH: thus, in an ancient inſcription mentioned by Gruter, Obrendario is uſed for Ofrendario.

As a numeral, B was uſed by the Greeks and Hebrews to denote 2; but among the Romans for 300, and with a daſh over it (thus $\bar{B}$) for 3000.

B is alſo uſed as an abbreviation. Thus B. A. ſtands for batchelor of arts; B. L. for bachelor of laws; and B. D. for bachelor of divinity. B. F. in the preface to the decrees, or ſenatus-conſulta of the old Romans, ſignified bonum factum. In muſic, B ſtands for the tone above A; as B♭, or ♭B, does for B flat, or the ſemitone major above A. B alſo ſtands for baſs; and B. C. for baſſo continuo, or thorough baſs.

BAAL, the ſame as BEL, or BELUS, was an idol of the Chaldeans, and Phœnicians, or Canaanites. The former worſhipped Mars under this name, according to Joſephus; who, ſpeaking of Thurus the ſucceſſor of Ninus, ſays, "To this Mars the Aſſyrians erected the firſt ſtatue, and worſhippid him as a god, calling him Baal."

It is probable the Phœnicians worſhipped the ſun under the name of Baal; for Joſiah, willing to make ſome amends for the wickedneſs of Manaſſeh, in worſhipping Baal and all the hoſt of heaven, "put down the idolatrous prieſts that burnt incenſe unto Baal, to the ſun, and to the moon, and to the planets, and to all the hoſt of heaven. And he took away the horſes that the kings of Judah had given to the ſun, and burned the chariots of the ſun with fire." 2 Kings c. xxiii. v. 5. 11.

The word Baal is often joined with the name of ſome falſe god, as Baal-berith, Baal-peor, Baal-zephon, and the like.

It paſſed from the Phœnicians to the Carthaginians, who were a colony of the Phœnicians; as appears from the Carthaginian names, Hannibal, Aſdrubal, &c. according to the cuſtom of the Eaſt, where kings and great men added to their own names thoſe of their gods.

It is frequently mentioned in Scripture in the plural number Baalim; which may ſignify, either that the name Baal was given to ſeveral different gods; or that there were many ſtatues, bearing different appellations, conſecrated to this idol.

BAAL BERITH, was the god of the Shechemites, and worſhipped by the idolatrous Iſraelites, Judges viii. 33.

BAAL GAD, BAGAD, or BEGAD, in mythology, was the idol of the Syrians, and ſignifies the god of chance, or fortune.

BAAL PEOR, BAAL PHEGOR, or BEEL PHEGOR, an idol of the Moabites and Midianites.

BAALZEBUB, BEELZEBUB, or BELZEBUB, was the idol, or god, of the Ekronites. In Scripture he is called the prince of devils. His name is rendered the lord of flies, or the god of flies, which ſome think was a mock appellation beſtowed on him by the Jews. He had a famous temple and oracle at Ekron.

Ahaziah king of Iſrael, having fallen from the terrace of his houſe into a lower room, and being dangerouſly hurt, ſent to conſult this deity, to know if he ſhould be cured of his wounds, for which idolatry the prophet was ſent to reprove him, and warn him of the judgment of God for his backſliding.

BAANITES, in church hiſtory, ſignify the followers of Baanes, a ſtrict diſciple of Menichea, in the beginning of the 9th century.

BABBLING, among hunters, is when the hounds are too buſy when they have got a good ſcent.

BABBLING, in the menage, ſignifies when the hounds or beagles have got a good ſcent, and are too buſy to purſue it.

BABOON, in tetrapodology, ſignifies a larger ſpecies of the Simia genus of quadrupeds in the order of primates, under which genera the various ſorts will be fully explained.

BABYLONICA TEXTA, a rich ſort of weavings, or hangings, denominated from the city Babylon, where the practice of interweaving divers colours in their hangings was firſt obtained: hence Babylonic garments, Babylonic ſkins, Babylonic carpets, houſings, &c.

Babylonica ſolana, coverings laid over couches, &c. painted with gold, purple, and other colours.

BABYLONICS, BABYLONICA, in literary hiſtory, ſignify fragments of the ancient hiſtory of the world, ending 267 years before Chriſt; and compoſed by Beroſſus, a prieſt of Babylon, about the time of Alexander. Babylonics are frequently cited in ancient writers by the title of Caldaics. The Babylonics were very conſonant with Scripture, as Joſephus and the ancient Chriſtian chronologers aſſure; whence the author is uſually ſuppoſed to have conſulted the Jewiſh writers. Beroſſus ſpeaks of an univerſal deluge, an ark, &c. He reckons ten generations between the firſt man and the deluge; and marks the duration of the ſeveral generations by ſaroi, or periods of 223 lunar months; which, reduced to years, differ not much from the chronology of Moſes.

The Babylonics conſiſted of three books, including the hiſtory of the antient Babyloneans, Medes, &c. But only a few imperfect extracts are now remaining of the work; preſerved chiefly by Joſephus and Syncellus, where all the paſſages of citations of ancient authors out of Beroſſus are collected with great exactneſs.

BABYROUSSA, or INDIAN HOG, in tetrapodology, is a ſynonime of a ſpecies of ſus.

BAC, in navigation, ſignifies a praam, or ferry boat.

BAC, in brewing, is a large flat veſſel into which the wort is put to ſtand and cool before boiling. The ingredients of beer paſs through three different kinds of veſſels. They are maſhed in one, worked in another, and cooled in a third.

BAC, in diſtillery, is a veſſel into which the liquor to be fermented is pumped from the cooler, in order to be worked with yeaſt or barm.

BACCA, BERRY, in botany, ſignifies ſuch fruits as conſiſt of a pericarpium full of juice and ſeeds, without any valves or covers, except the rind.

BACCALARIA, in hiſtory, denotes a kind of country farms, conſiſting of ſeveral cottages, and their appurtenances.

BACCHÆ, in antiquity, were the prieſteſſes of Bacchus, who celebrated the orgia, or myſteries of that god. The word alſo implies the ivy crowns or garlands worn by the prieſts of Bacchus, in offering ſacrifices to him.

BACCHANALIA, were feaſts celebrated in honour of Bacchus by the ancient idolaters. The two moſt remarkable were called the greater and leſſer. The latter, was called Lunæa, from a word ſignifying a wine preſs, and held in the open fields about autumn; the greater, called Dioniſia, from one of the names of Bacchus, was celebrated in the city, about the ſpring time. Both theſe feaſts were accompanied with games, ſpectacles, and theatrical repreſentations, and it was at this ſeaſon the poets contended for the prize of poetry.

BACCHANALIAN *Song*, is a compoſition to promote jollity and mirth.

BACCHARIS, Ploughman's Spikenard, in botany, is a genus of the poligamia ſuperflua order, belonging to the ſyngeneſia claſs of plants; and in the natural method ranking under the 49th order, compoſitæ diſcoides. It has a naked receptacle, and hairy pappus; a cylindrical imbricated calyx, and feminine florets mixed with hermaphrodite ones.

There are ſeven ſpecies, all natives of warm climates; but only merit notice, the two following, viz. 1. The ivæfolia, or African tree-groundſel, is a native of the Cape of Good Hope, as alſo of Peru and other warm parts of America.

It may be propagated either by cuttings or ſeeds, which ripen well in this country.

2. The halimifolia, or Virginian groundſel tree, is a native of Virginia and other parts of North America. It may be propagated by cuttings; and will live very well in the open air, though ſevere froſt will ſometimes deſtroy it.

BACCHIFEROUS PLANTS, in botany, denote all ſuch as bear berries; and are thus characterized; the fruit is covered with a thin membrane, in which is contained the pulp, which incloſes the ſeed within its ſubſtance.

BACCHUS, in mythology, denotes the god of wine; the ancient heathens worſhipped him in different countries under the following appellations: in Egypt, he was called Oſiris; in Myſia, Fanaces; in India, Dioniſius; Liber, throughout the Roman dominions; Adoneus, in Arabia; and Pantheus, by the Lucanians.

The great Bacchus, according to Sir Iſaac Newton, flouriſhed but one generation before the Argonautic expedition. This Bacchus, ſays Hermippus, was potent at ſea, conquered eaſtward as far as India, returned in triumph, brought his army over the Helleſpont, conquered Thrace, and left muſic, dancing, and poetry there. And, according to Diodorus Siculus, it was the ſon of Semele who invented farces and theatres, and who firſt eſtabliſhed a muſic ſchool, exempting from all military functions ſuch muſicians as diſcovered great abilities in their art; on which account, ſays the ſame author, muſicians formed into companies have ſince frequently enjoyed great privileges.

Bacchus was regarded by the Athenians not only as the god of wine, but of ſong; and it muſt be owned, that his followers, in their cups, have been much inclined to ſinging ever ſince. Indeed we are certain, that in none of the proceſſions, triumphs, and feſtivals, inſtituted by the ancients to the honour and memory of this prince of *bons vivans*, muſic was forgotten, as may be ſtill gathered from ancient ſculpture, where we find not only that muſicians, male and female, regaled him with the lyre, the flute, and with ſong; but that he was accompanied by fawns and ſatyrs playing upon timbrels, cymbals, bagpipes, and horns: theſe Suidas calls his minſtrels; and Strabo gives them the appellations of Bacchi, Sileni, Satyri, Bacchæ, Lenæ, Thyæ, Mamillones, Naiades, Nymphæ, and Tityri. Theſe repreſentations have furniſhed ſubjects for the fineſt remains of ancient ſculpture; and the moſt voluptuous paſſages of ancient poetry are deſcriptions of the orgies and feſtivals of Bacchus.

Bacchus, in ichthyology, denotes the mixon, or mullet, of which it is a ſynonyme.

BACCOFOE, or Crucifix plant, in botanp, is a variety of the banana, a native of Guinea in Africa, and yields a fruit of an excellent flavour. Phil. Tranſ. N° 108.

BACHELOR, or **Batchelor**, is a general term for a man not married, or who is yet in a ſtate of celibacy.

The Roman cenſors frequently impoſed fines on old bachelors. Dionyſſius Halicarnaſſus mentions an old conſtitution, by which all perſons of full age were obliged to marry. But the moſt celebrated law of this kind was that made under Auguſtus, called the *lex Julia de maritandis ordinibus*; by which bachelors were made incapable of legacies or inheritances by will, unleſs from their near relations. This law cauſed many to marry, according to Plutarch's obſervation, not ſo much for the ſake of raiſing heirs to their own eſtates, as to make themſelves capable of inheriting thoſe of other men.

The Jewiſh rabbins maintain, that, by the laws of Moſes, every man is obliged in conſcience to marry at 20 years of age: this makes one of their 613 precepts. The Chriſtian religion is more indulgent to the bachelor ſtate: for the ancient church recommended it in ſome circumſtances preferable to, the matrimonial ſtate. In the canon law, we find injunctions on bachelors, when arrived at puberty, either to marry or to turn monks and profeſs chaſtity in earneſt.

In England there was a tax on bachelors, after 25 years of age, 12l. 10s. for a duke, and proportionably down to a common perſon 1s. by 7 Will. III. 1695.

At preſent, they are taxed by an extra duty on their ſervants. Every man of the age of 21 years and upwards, never having been married, who ſhall keep one male ſervant or more, ſhall pay 1l. 5s. for each above or in addition to the ordinary duties leviable for ſervants. Every man of the age of 21 years and upwards, never having been married, keeping one female ſervant, ſhall pay 2s. 6d. in addition to the former 2s. 6d.; 5s. in addition for each, if he has two female ſervants; and 10s. in addition for each for three or more female ſervants.

Knights **Bachelors**, were the moſt ancient, but the loweſt order of knights in England; known by the name of knights only.

Bachelors, in an univerſity ſenſe, are thoſe perſons that have attained to the baccalaureate, or who have taken the firſt degree in the liberal arts and ſciences.

The degree of bachelor was firſt introduced in the 13th century by Pope Gregory IX. but it remains ſtill unknown in Italy.

At the univerſity of Oxford, before a perſon is intitled to the degree of bachelor of arts, he muſt have ſtudied there four years; three years more are requiſite to become maſter of arts; and then ſeven more to commence a bachelor of divinity.

At Cambridge, to commence bachelor of arts, a perſon muſt have been admitted near four years; and above three years more before he can commence maſter; and then ſeven more to become a bachelor of divinity. He may commence bachelor of law after having ſtudied it ſix years.

At Paris, to paſs bachelor in theology, a perſon muſt have ſtudied two years in philoſophy and three years in theology, and held two acts of examination in the Sorbonne.

Bachelors in the canon law are admitted after two years ſtudy in the ſame, and ſuſtaining an act according to the forms.

A bachelor of phyſic muſt have ſtudied two years in medicine after having been four years maſter of arts in the univerſity, and ſtood an examination; after which he is inveſted with the fur, in order to be licenſed.

BACILLA, **Baccilli**, or **Baculi**, in pharmacy, is of a ſynonymous meaning with lozenge. Hence, all medicines made up in the form of a lozenge, are called baculics.

BACK, **Back Bone**, in anatomy, is the ſame as Spine.

Back Gammon, an ingenious game played with dice, upon a table, by two perſons.

Back Painting, ſignifies the method of painting mezzotinto prints, paſted on glaſs, with oil colours. The art of which conſiſts chiefly in laying the print upon crown glaſs, of ſuch a ſize ſo as to fit the print. In order to which take the print, and put it in clean water until it is quite ſoaked through, then take it out and lay it on two ſheets of paper, and cover it with two more; and let it lie there a little time to ſoak out the moiſture. In the mean time take the glaſs and ſet it near the fire to warm; then take the Straſburg turpentine, warm it over the fire till it is grown fluid, then with a hog's hair bruſh ſpread the turpentine very ſmoothly and evenly on the glaſs. When this has been done, take the mezzotinto print from between the papers, and lay it upon the glaſs; beginning firſt at one end, rubbing it down gently as you go on, till it lies quite cloſe. Then, with your fingers, rub or roll off the paper from the back ſide of the print, till it looks black, i. e. till you can ſee nothing but the print, like a thin film, left upon the glaſs, then lay it to dry. When it is quite dry, varniſh it over with ſome white tranſparent varniſh, that the print may be ſeen through it; and then it is fit for painting. Having thus far proceeded, and your oil-colours prepared, ground very fine, and tempered up very ſtiff, lay on the back ſide of the tranſparent prints ſuch colours as each particular part requires; letting the maſter lines of the print ſtill guide your pencil, and ſo each particular colour will lie fair to the eye on the other ſide of the glaſs, and look as well as a painted piece, if it be done neatly. The ſhadows of the print are generally ſufficient for the ſhadow of every colour; but if you have a mind to give a ſhadow by your pencil, then let the ſhadows be laid on firſt, and the other colours afterwards. In laying on the colours you need not be curious as to their ſmoothneſs, as it is not at all requiſite here, where the chief aim, is only to have the colours appear well on the fore ſide of the print; and therefore the only care to be uſed in this work, is to lay the colours on thick enough, that its body may ſtrike the colour of it plainly through the glaſs.

Back Stays, of a ſhip, are the ropes belonging to the main and fore-maſt, and likewiſe to the maſts belonging to them; ſerving to keep them from pitching forwards or overboard.

BACKING *of a Colt*, in horſemanſhip, ſignifies the operation of breaking him to the ſaddle, or bringing him to endure a rider.

Backing *the Sails*, in navigation, is to arrange them in a ſituation that will force the ſhip to retreat, or move backwards. This is, however, only done in narrow channels, when a ſhip is carried along ſidewiſe by the tide or current, and wants to avoid any thing that may interrupt her progreſs, as ſhoals, veſſels at anchor, &c. or in the line of battle, when a ſhip wants to be immediately oppoſite to another with which ſhe is engaged.

BACKS, in curriery, denote the thickeſt and beſt tanned hides, uſed chiefly for ſoles of ſhoes, commonly called butt leather.

BACULARIUS, is an eccleſiaſtical apparitor, or verger, who carries a ſtaff, baculus, in his hand, as an enſign of his office.

BACULE, in fortification, is a kind of portculis, or gate, made like a pit fall with a counterpoiſe, and ſupported by two great ſtakes. It is uſually made before the corpade-guard, not far from the gate of a fortified place.

BACULOMETRY, in geometry, ſignifies the art of meaſuring acceſſible or inacceſſible heights, by the help of one or more baculi, ſtaves, or rods.

BADGE, in naval architecture, ſignifies a ſort of ornament placed on the outſide of ſmall veſſels, whether ſhips, ſnows, brigs, or ſloops, very near the ſtern, containing either a window for the convenience of the cabin, or a repreſentation of it. It is commonly decorated with marine figures, martial inſtruments, or ſuch like emblems.

BADGER, in tetrapodology, is the Engliſh name of a ſpecies of urſus.

Badger, in old law books, ſignifies one that was licenſed to buy corn in one place and carry it to another to ſell, without incurring the puniſhment of an engroſſer.

BADIAGA, in the meteria medica, is the name of a ſort of ſpongy plant, common in the ſhops at Moſcow, and ſome other northern kingdoms. The uſe of it is the taking away the livid marks from blows and bruiſes, which the powder of this plant is ſaid to do in a night's time.

BADIAN, **Badiana**, or **Bandian**, is the ſeed of a tree which grows in China, and ſmells like aniſe-ſeed. The Chineſe, and the Dutch in imitation of them, ſometimes uſe the badiane to give their tea an aromatic taſte.

BADIGEON, among artiſts, is a mixture of plaſter and free ſtone, well ground together, and ſifted; and uſed by ſtatuaries to fill up the little holes, and repair the defects in ſtones, out of which they make their ſtatues, and other works.

The ſame term is alſo uſed by joiners, for ſaw duſt mixed with ſtrong glue, with which they fill up the chaps and other defects in wood, after it is wrought.

BADOUSE, in botany, is a ſynonyme of a ſpecies of the gooſeberry tree. The name is peculiar to the Chineſe and Eaſt Indians. The ſize is from that of a walnut to a large apple. It is clear and tranſparent, and of ſalutary effect in the act of digeſtion.

BÆCKEA, in botany: is a genus of the octandria order, belonging to the monogynia claſs of plants. The calyx is a permanent perianthium, conſiſting of a ſingle funnel ſhaped leaf, cut into five ſegments at the brim; the corolla conſiſts of five roundiſh ſpreading petals inſerted into the calyx; the pericarpium is a globoſe capſule, and made up of four valves, containing four cells, in which are a few roundiſh angular ſeeds.

BAFFETAS, or **Bastas**, in commerce, is a kind of cloth made of coarſe white cotton thread, which comes from the Eaſt Indies.

BAG, in commerce, is a term ſignifying a certain quantity of ſome particular commodity: as a bag of almonds, for inſtance, is about 300 weight; of aniſe-ſeeds, from 300 to 400, &c.

Bag, among farriers, is when, in order to retrieve a horſe's loſt appetite, they put in an ounce of aſa-fœtida, and as much powder of ſavin, into a bag, to be tied to the bit, keeping him bridled for two hours, thrice a day; as ſoon as the bag is taken off, he will fall to eating.

BAGADAT, in ornithology, ſignifies the columba tabellaria, or carrier pigeon. This name is derived from Bagdat, a city of Aſia in Irak Arabia, from whence this ſpecies were firſt imported into Europe.

BAGAUZE, in mercantile or manufacture, ſignifies the ſtate of the ſugar canes, after they have paſſed through the mill. In this ſtate, and under this denomination, they are dried, and then become curoſſes, and are uſed for boiling the ſugar.

BAGGAGE, in military matters, denotes the cloathes, tents, and utenſils of divers ſorts, proviſions, and other neceſſaries belonging to an army.

Before a march, the waggons with the baggage are marſhalled according to the rank which the ſeveral regiments bear in the army; being ſometimes ordered to follow the reſpective columns of the army, ſometimes to follow the artillery, and ſometimes to form a column by themſelves. The general's baggage marches firſt; and each waggon has a flag, ſhowing the regiment to which it belongs.

BAGNIO, an Italian word, ſignifying a bath. In England the term implies an houſe with conveniences for bathing, cupping, ſweating, and cleanſing the body; and alſo for brothels.

In Turky it is become a general name for the priſons where the ſlaves are incloſed, it being uſual in theſe priſons to have baths.

BAG-PIPE, is a muſical inſtrument of the wind kind, chiefly uſed in Scotland and Ireland. The peculiarity of the bag-pipe, and from which it takes its name, is, that the air which blows it is collected into a leathern bag, from whence it is preſſed out by the arm into the pipes. Theſe pipes conſiſt of a baſs, and tenor or treble; which are different according to the ſpecies of the pipe. The baſs is called the drone, and the tenor or treble the chanter.

BAGRE, in ichthyology, is a ſpecies of the ſilurus. There are many varieties, moſtly natives of the American ſeas.

BAGUETTE, in architecture, is a ſmall round moulding, leſs than an aſtragal, and ſo called from the reſemblance it bears to a ring. But when the baguette is enriched with ornaments, it changes its name, and is called a chaplet; and unornamented it is called a bead.

BAHAR, or Barre, in commerce, are weights uſed in ſeveral places in the Eaſt Indies.

There are two of theſe weights; one called the great bahar, with which they weigh pepper, cloves, nutmegs, ginger, &c. and contains 550 pounds of Portugal, or about 524 lb. 9 oz. avoirdupois weight. With the other called the little bahar, they weigh quickſilver, vermilion, ivory, ſilk, &c. It contains about 437 lb. 9 oz. avoirdupois weight.

BAHIR, is an Hebrew term, ſignifying famous or illuſtrious; but particularly uſed for a book of the Jews, treating of the profound myſteries of the cabbala, being the moſt ancient of the Rabbinical works.

BAHIRA, in Arabian antiquity, ſignifies a freed ſlave: yet we find that Calmet applies it only to the camel, who in return for ſeven years faithful ſervices, was wont to be freed from future labour. His ear was ſlit as a memorial; and thus he became a monument of veneration during the reſt of his life.

BAIJ, or Baija, in the menage, ſignifies the foxing or clipping of the ears of a horſe, in order to make him lively and ſuſceptible of feeling.

Poneys and dull varieties of the ſpecies are foxed merely to increaſe their ſenſibility, which proficients in menagerie aver, that this cuſtom takes the deſired effect.

BAIL, Ballium, (from the French bailler, which comes originally from the Greek βαλλειν, and ſignifies to deliver into hands), in law ſignifies the freeing or ſetting at liberty of one arreſted or impriſoned upon any action, either civil or criminal, on ſurety taken for his appearance at a certain day and place.

By this means the party reſtrained is delivered into the hands of thoſe that bind themſelves for his forthcoming, in order to a ſafe keeping and protection from priſon; and finally to ſatisfy the condemnation and coſts, or render the defendant into the hands of the plaintiff, or to priſon, as the caſe may be.

With reſpect to bail in civil caſes, it is to be obſerved, that it is either common or ſpecial. Common bail is in actions of ſmall concernment, being called common, becauſe any ſureties in that caſe are taken; ſpecial bail in cauſes of greater weight, as actions upon bonds, or ſpeciality, &c. where the debt is ſued for by ſpecial original in ſuch caſes ſubſidy men at leaſt, and thoſe according to the value: but modern practice calls all actions above 10l. ſpecial.

The commitment of a perſon being only for ſafe cuſtody, wherever bail will anſwer the ſame intention, it ought to be taken; as in moſt of the inferior crimes: but in felonies, and other offences of a capital nature, no bail can be a ſecurity equivalent to the actual cuſtody of the culprit.

Bail may be taken either in court, or at a judges chambers, but in ſome particular caſes, by the ſheriff or other magiſtrate; but moſt uſually by the juſtices of the peace. To refuſe or delay to bail any perſon bailable, is an offence againſt the liberty of the ſubject, in any magiſtrate, by the common law; as well as by the ſtatute Weſtm. 1. 3 Edw. I, c. 15. and the hæbeas corpus act, 31 Car. II. c. 2. And, leſt the intention of the law, ſhould be fruſtrated by the juſtices requiring bail to a greater amount than the nature of the caſe demands, it is expreſsly declared by ſtatute 1 W. & M, ſ. 2, c. 1. that exceſſive bail ought not to be required; though what bail ſhall be called exceſſive, muſt be left to the courts, on conſidering the circumſtances of the caſe, to determine. And on the other hand, if the magiſtrate takes inſufficient bail he is liable to be fined, if the criminal doth not appear.

In civil caſes, every defendant is bailable.

In criminal matters all offences either againſt the common or ſtatute law that are below felony, the offender ought to be admitted to bail, unleſs prohibited by ſome ſpecial act of parliament. By the ancient common law, before and ſince the conqueſt, all felonies were bailable, till murder was excepted by ſtatute: ſo that perſons might be admitted to bail almoſt in every caſe. But the ſtatute Weſt. 1. 3 Ed. I. c. 15. takes away the power of bailing in treaſon, and in divers inſtances of felony. The ſtatutes 23 Hen. VI. c. 9. and 1 and 2 Ph. & Mar. c. 13. gave farther regulations in this matter: and upon the whole we may collect that in the following inſtances no juſtices of the peace can bail. 1. Upon an accuſation of treaſon: 2. Of murder: 3. In caſe of manſlaughter, if the priſoner be clearly the ſlayer, and not barely ſuſpected to be ſo; or if any indictment be found againſt him: 4. Such as, being committed for felony, have broken priſon; becauſe it not only carries a preſumption of guilt, but is alſo ſuperadding one felony to another: 5. Perſons outlawed: 6. Such as have abjured the realm: 7. Perſons taken with the mainour, or in the fact of felony: 8. Perſons charged with Arſon: 9. Excommunicated perſons, taken by writ de excommunicato capiendo: all which are clearly not admiſſible to bail by the juſtices. But in caſes of a dubious nature, as, thieves openly defamed and known: perſons charged with other felonies, or manifeſt and enormous offences, not being of good fame: and, acceſſories to felony, that labour under the ſame want of reputation: theſe ſeem to be at the diſcretion of the juſtices. However perſons of good fame, charged with a bare ſuſpicion of manſlaughter, or other infamous homicide; or ſuch perſons being charged with petit larceny or any felony, not before ſpecified: or, with being acceſſory to any felony, they may be held to bail. Laſtly, the court of king's bench may bail for any crime whatſoever, whither treaſon, murder, or any offence, according to the circumſtances of the caſe. And herein the wiſdom of the law is very manifeſt. To allow bail to be taken commonly for ſuch enormous crimes, would greatly tend to elude the public juſtice: and yet there are caſes, though they rarely happen, in which it would be hard and unjuſt to confine a man in priſon, though accuſed even of the greateſt offence. The law has therefore provided only one court, which has a diſcretionary power of bailing in any caſe.

Clerk of the Bails, is an officer belonging to the court of the King's bench: he files the bail-pieces taken in that court, and attends for that purpoſe in court during its ſitting, and in the evening at the judges chambers, whoſe turn it is to take bail: for in term time the judges regularly attend in their turns. With reſpect to the order and practice of this office, ſee the Syſtem of Law.

Bail, or Bale, in the ſea language, is the ſeamen's throwing the water by hand baſkets out of the ſhip's or boat's hold, which is called *bailing*. They alſo call thoſe hoops that bear up the tilt of a boat, its *bail*.

BAILIE, is the name of a magiſtrate in royal boroughs, and of the judge appointed by a baron over lands erected into a barony.

BAILIFF, *Ballivus*, from the French word *bayliff*, that is, *præfectus provinciæ*: and as the names, for the office itſelf was anſwerable to that of France; were there are eight parliaments, which are high courts, from whence there lies no appeal, and within the precincts of the ſeveral parts of that kingdom which belong to each parliament there are ſeveral provinces to which juſtice is adminiſtered by certain officers called bailiffs; and in England there are ſeveral counties in which juſtice hath been adminiſtered to the inhabitants by the officer who is now called ſheriff.

In the ſtatute of Magna Charta, cap. 28, and 14 Ed. 3. c. 9. the word bailiff ſeems to compriſe as well ſheriffs as bailiffs of hundreds. As the realm is divided into counties, ſo every county is divided into hundreds; within which in ancient times the people had juſtice adminiſtered to them by the officers of every hundred. But now the hundred courts, except certain franchiſes, are included in the county-courts; and the bailiff's name and office is grown into diſrepute, they being generally officers to ſerve writs, &c. within their liberties. Though, in other reſpects, the name is ſtill in good eſteem; for the chief magiſtrates in divers towns are called bailiffs or bailies; and ſometimes the perſons to whom the king's caſtles are committed are termed bailiffs, as the bailiff of Dover caſtle, &c. &c.

Of the ordinary bailiffs there are ſeveral ſorts, viz. ſheriff's bailiffs, bailiffs of liberties, &c.

Sheriff's bailiffs, or ſheriff's officers, are either bailiffs of hundreds, or ſpecial bailiffs. Bailiffs of hundreds are officers appointed over thoſe reſpective diſtricts by the ſheriffs, to collect fines; ſummon juries; to attend the judges and juſtices at the aſſizes, and quarter ſeſſions; and alſo to execute writs and proceſs in the ſeveral hundreds.

Bailiffs of liberties are thoſe bailiffs who are appointed by every lord within his liberty, to execute proceſs, and do ſuch offices therein as the bailiff errant doth at large in the county; but bailiffs errant or itinerant, to go up and down the county to ſerve proceſs, are out of uſe in the practice of the common law.

There are alſo bailiffs of foreſts, and bailiffs of manors, who direct huſbandry, fell trees, gather rents, pay quit-rents, &c.

Water Bailiff, is an officer appointed in all port-towns, for the ſearching of ſhips, gathering the toll for anchorage, &c. and arreſting perſons for debt, &c. on the water.

BAILIWICK, Bailywick, or Baylywick, is that liberty, which is exempted from the ſheriff of the county; over which liberty the lord thereof appoints his own bailiff, with the like power within his precinct, as an under ſheriff exerciſes under the high ſheriff of the county.

Bailiwick alſo ſignifies the precinct of a ſheriff or a bailiff, or the place within which his juriſdiction is terminated: the return of writs ſpecify this.

BAILMENT, in law, ſignifies a delivery of goods in truſt, upon a contract, expreſſed or implied, that the truſt ſhall be faithfully executed on the part of the bailee: vide ſtatute 30 Geo. II. c. 24.

If a landlord diſtrains goods for rent, or a pariſh officer for taxes, theſe for a time are only a pledge in the hands of the diſtrainers; and they are bound by an implied contract in law to reſtore them on payment of the debt, duty, and expences, before the time of ſale; or when ſold, to render back the overplus.

BAILO, at Conſtantinople, ſignifies the ambaſſador of the republic of Venice, who reſides at the Porte. This miniſter, beſides his political charge, acts there the part of a conſul of Venice.

BAIOCCO, is a copper-coin, current at Rome, and throughout the whole ſtate of the church, ten of which make a julio, and an hundred a Roman crown.

BAIRAM, or Beiram, is a Turkiſh word which ſignifies a ſolemn feaſt. The Mahometans have two Bairams, the great and the leſſer. The leſſer Bairam is properly that held at the cloſe of the faſt Ramazan, beginning with the firſt full moon in the following month Shawal. This is called in Arabic *Id al Fetz, or the Feaſt of breaking the Faſt*; and by Europian writers, *the Turkiſh Eaſter*, becauſe it ſucceeds Ramazan, which is their Lent, more uſually the Great Bairam, becauſe obſerved with great ceremony and rejoicing at Conſtantinope, and throughout all Turkey, for three days, and in Perſia for five or ſix days, to make amends for the mortification of the preceding month. The feaſt commencing with the new moon, the Mahometans are very ſcrupulous in obſerving the time when the new moon commences; to which purpoſe, obſervers are ſent to the tops of the higheſt mountains, who the moment they ſpy the appearance of a new moon, run to the city, and proclaim Muzhdaluk, "welcome news;" as it is the ſignal for beginning the feſtivity. The Great Bairam, is properly that held by the pilgrims at Mecca, commencing on the tenth of Dhu Ihajia, when the victims are ſlain, and laſting three days. This is called by the Arabs, *Id al alha*, that is, *the feaſt of ſacrifice*, as being celebrated in memory of the intended ſacrifice of Abram, whoſe ſon God redeemed with a great victim. By European writers it is called the Leſſer Bairam, as being leſs taken notice of by the generality of the people who are not ſtruck with it, becauſe the ceremonies, with which it is obſerved, are performed at Mecca, the only ſcene of the ſolemnity. On the feaſt of Bairam, after throwing little ſtones, one after another, into the valley of Mina, they uſually kill a ſheep, a goat, a bullock, or even a camel; and after giving a part thereof to the poor, eat the reſt with their friends. After this, they ſhave themſelves. The ſecond is a day of reſt. And on the third, they ſet out to return home.

BAIT, in ichthyology, ſignifies the fry of ſeveral ſorts of fiſh, for which it is a ſynonymous epithet. Near London, during the ſummer months, ſeveral varieties are caught in the river Thames, and highly eſteemed by the citizens of London. They are termed *white bait*.

Bait, among fiſhermen, implies a ſubſtance proper to be faſtened to a hook, in order to catch the different ſorts of fiſh.

BAITING, is the act of ſmaller or weaker beaſts attacking and haraſſing greater and ſtronger ones. In this ſenſe is ſignified the baiting of bulls or bears by maſtiffs, or bull-dogs, &c.

The ſhameful practice of bull-baiting was firſt introduced into England as an amuſement in the reign of king John, about 1209.

BALA, in botany, is ſynonymous with Banana, the Plantain, or Plantane Tree.

BALAAMITES, in eccleſiaſtical hiſtory, denotes the ſame as the Nicolatans, of whom Saint John in the Revelation ſpeaks of in a moſt awful judgment againſt the evil of their ways.

BALÆNA, or Whale, in ichthyology, is a genus of the 4th claſs, belonging to the cetaceous order. The characters of which are: the balæna, in place of teeth, has a horny plate on the upper jaw, and a double fiſtula or pipe for throwing out water. The ſpecies are four, viz.

1. The myſticetus, or common whale, which has many turnings and windings in its noſtrils, and has no fin on the back. This is the largeſt of all animals; it is even at preſent ſometimes found in the northern ſeas 90 feet in length; but formerly they were taken of a much greater ſize, when the captures were leſs frequent, and the fiſh had time to grow. Such is their bulk within the arctic circle; but in thoſe of the torrid zone, where they are unmoleſted, whales are ſtill ſeen 160 feet long. The head is very much diſproportioned to the ſize of the body, being one third of the ſize of the fiſh: the under lip is much broader than the upper. The tongue is compoſed of a ſoft ſpungy fat, capable of yielding five or ſix barrels of oil. The gullet is very ſmall for ſo vaſt a fiſh, not exceeding four inches in width. In the middle of the head are two orifices, through which it ſpouts water to a vaſt height, and with a great noiſe, eſpecially when diſturbed or wounded. The eyes are not larger than thoſe of an ox, and when the cryſtalline humour is dried, it does not appear larger than a pea. They are placed towards the back of the head, being the moſt convenient ſituation for enabling them to ſee both before and behind; as alſo to ſee over them, where their food is principally found. They are guarded by eye-lids and eye-laſhes, as in quadrupeds; and they ſeem to be very ſharp ſighted. Nor is their ſenſe of hearing in leſs perfection; for they are warned at great diſtance of any danger preparing againſt them.

What is called whalebone, adheres to the upper jaw; and is formed of thin parallel laminæ, ſome of the longeſt four yards in length: of theſe there are commonly 350 on each ſide, but in very old fiſh more; about 500 of them are of a length fit for uſe, the others being too ſhort. They are ſurrounded with long ſtrong hair, not only that they may not hurt the tongue, but as ſtrainers to prevent the return of their food when they diſcharge the water out of their mouths. The real bones of the whale are hard, porous, and full of marrow. Two great ſtrong bones ſuſtain the upper lip, lying againſt each other in the ſhape of an half moon.

The tail is broad and ſemilunar; and when the fiſh lies on one ſide, its blow is tremendous. The tail alone it makes uſe of to advance itſelf forward in the water; and it is ſurpriſing to ſee with what force and celerity its enormous bulk cuts through the ocean. The fins are only made uſe of for turning in the water, and giving a direction to the velocity impreſſed by the tail. The female alſo makes uſe of them, when purſued, to bear off her young, clapping them on her back, and ſupporting them by the fins on each ſide from falling off.

The whale varies in colour; the back of ſome being red, the belly generally white. Others are black, ſome mottled, others quite white; according to the obſervation of Martin, who ſays, that their colours in the water are extremely beautiful, and that their ſkin is very ſmooth and ſlippery. The outward or ſcarf ſkin of the whale is no thicker than parchment; but this removed, the real ſkin appears, of about an inch thick, and covering the fat or blubber that lies beneath: this is from eight to twelve inches in thickneſs; and is, when the fiſh is in health, of a beautiful yellow. The penis is eight feet in length, incloſed in a ſtrong ſheath. The teats in the female are placed in the lower part of the belly.

In copulation, the female joins with the male, as is aſſerted, more humano; and once in two years feels the acceſſes of deſire. The whale goes with young nine or ten months, and is then fatter than uſual, particularly when near the time of bringing forth. It is ſaid that the embryo, when firſt perceptible, is about 17 inches long, and white; but the cub, when excluded, is black, and about 10 feet long. She generally produces one young one, and never above two. When ſhe ſuckles her young, ſhe throws herſelf on one ſide on the ſurface of the ſea, and the young one attaches itſelf to the teat.

Nothing can exceed the tenderneſs of the female for her offſpring; ſhe carries it with her wherever ſhe goes, and, when hardeſt purſued, keeps it ſupported between her fins. Even when wounded, ſhe ſtills claſps her young one; and when ſhe plunges to avoid danger, takes it to the bottom; but riſes ſooner than uſual, to give it breath again. The young ones continue to ſuck at the teats for a year; during which time, they are called by the ſailors, ſhort heads. They are then extremely fat, and yield above 50 barrels of blubber. The mother at the ſame time is exceeding lean and emaciated. At the age of two years they are called ſtunts, as they do not thrive much immediately after they ceaſe to ſuck: they then yield ſcarcely more than 20 or 24 barrels of blubber: from that time forward they are called ſkull fiſh, and their age is wholly unknown.

Every ſpecies of whale propagates only with thoſe of its own kind, and does not at all mingle with the reſt: however, they are generally ſeen in ſhoals, of different kinds together, and make their migrations in large companies from one ocean to another. They are gregarious animals; which implies their want of mutual defence againſt the invaſions of ſmaller, but more powerful fiſhes.

It ſeems aſtoniſhing, therefore, how a ſhoal of theſe enormous animals find ſubſiſtence together, when it would ſeem that the ſupplying even one with food would require greater plenty than the ocean could furniſh. To increaſe our wonder, we not only ſee them herding together, but uſually find them fatter than any animals whatever.

Linnæus ſays, the meduſa or ſea blubber, is ſufficient for their ſupply; and content with this ſimple food, it purſues no other animal, leads an inoffenſive life in its element, and is harmleſs in proportion to its ſtrength to do miſchief.

As the whale is an inoffenſive animal, it is not to be wondered that it has many enemies, willing to take advantage of its diſpoſition, and inaptitude for combat. There is a ſmall animal, of the ſhell fiſh kind, called the whale louſe, that ſticks to its body, as we ſee ſhells ſticking to the foul bottom of a ſhip. This inſinuates itſelf chiefly under the fins; and whatever efforts the great animal makes, it ſtill keeps its hold, and lives upon the fat, which it is provided with inſtruments to arrive at.

The ſword, however, is the whale's moſt terrible enemy. "At the ſight of this little animal," ſays Anderſon, "the whale ſeems agitated in an extraordinary manner; leaping from the water as if with affright: wherever it appears, the whale perceives it at a diſtance and flies from it in the oppoſite direction. I have been myſelf," continues he, "a ſpectator of their terrible encounter. The whale has no inſtrument of defence except the tail: with that it endeavours to ſtrike the enemy; and a ſingle blow taking place, would effectually deſtroy its adverſary: but the ſword fiſh is as active as the other is ſtrong, and eaſily avoids the ſtroke; then bounding into the air, it falls upon its great ſubjacent enemy, and endeavours not to pierce it with its pointed beak, but to cut it with its toothed edges. The ſea all about it is ſeen dyed with blood, proceeding from the wounds of the whale; while the enor-animal, vainly endeavours to reach its invader, and ſtrikes with its tail againſt the ſurface of the water, making a report at each blow louder than the noiſe of a cannon."

In calm whether, the fiſhermen lie upon their oars as ſpectators of this combat, until they perceive the whale at the laſt gaſp: then they row towards him; and his enemies retiring at their approach they enjoy the fruits of the victory.

The grampus, and other large fiſhes of the cetaceous order, are attacked and deſtroyed by the ſame enemy in a ſimilar manner. The whale has alſo another deſperate enemy, a ſpecies of the ſhark, of different ſizes from one to three fathoms; ſo voracious, that it tears large pieces of fleſh from the whale, as if they had been cut out with a knife.

To view theſe animals in a commercial light we muſt obſerve, that the Engliſh were late before they engaged in the whale fiſhery: it appears by a ſet of queries, propoſed by an honeſt merchant in the year 1575, in order to get information in the buſineſs, that we were at that time totally ignorant of it, being obliged to ſend to "Biſkaie for men ſkilful in the catching of the whale, and ordering of the oil; and one cooper ſkilful to ſet up the ſtaved caſk." This ſeems very ſtrange; for by the account Octher gives of his travels to king Alfred, near 700 years before that period, it is evident that he made that monarch acquainted with the Norwegians practiſing the whale-fiſhery; but it ſeems all memory of that gainful employ, as well as of that able voyager Octher, and all his important diſcoveries in the north, were loſt for near ſeven centuries.

It was carried on by the Biſcayeners long before we attempted the trade; and that for the ſake not only of the oil, but alſo of the whalebone, which they ſeem to have long trafficked in. The earlieſt notice we find of that article in our trade is by Hackluyt, who ſays it was brought from the Bay of St. Laurence by an Engliſh ſhip that went there for the barbes and fynnes of whales and train oil, A. D. 1594, and who found there 700 or 800 whale fynnes, part of the cargo of two great Biſkaine ſhips, that had been wrecked there three years before. Previous to that ladies' ſtays muſt have been made of ſplit cane, or ſome tough wood, as Mr. Anderſon obſerves in his Dictionary of Commerce; it being certain that the whale fiſhery was carried on, for the ſake of the oil, long before the diſcovery of the uſe of whalebone.

2. The phyſalus, or fin-fiſh, is diſtinguiſhed from the common whale by a fin on the back, placed very low and near the tail. The length is equal to that of the common kind, but much more ſlender. It is furniſhed with whale bone in the upper jaw, mixed with hairs, but ſhort and knotty, and of little value. The blubber alſo on the body of this kind is very inconſiderable. Theſe circumſtances, added to its extreme fierceneſs and agility, which renders the capture very dangerous, cauſe the fiſhers to neglect it.

The phyſalus inhabits the European and American oceans.

3. The boops, or pike headed whale, has a double pipe in its ſnout, three fins like the former, and a hard horney ridge on its back. The belly is full of longitudinal folds or rugæ. It frequents the northern ocean. This ſpecies takes its name from the ſhape of its noſe, which is narrower and ſharper pointed than that of other whales.

4. The muſculus has a double pipe in its front, and three fins; the under jaw is much wider than the upper one. It frequents the Scotch coaſts.

Linnæus very properly makes the phyſeter and delphinus, which are ranked among the whales by ſome writers, two diſtinct genera.

BALAM PULLI, in botany, is the trivial name of the tree which produces the tamarind of the ſhops.

BALAM ZUELLI, in botany, is a ſynonyme of the tea tree, an article in commerce imported from the Eaſt Indies, now well known to every individual in Europe who has arrived to the years of maturity. In theſe countries it is a morning and afternoon's beverage.

BALAMINE, in tetrapodology, denotes the diſtinctions in the hooves of quadrupeds; which are only thoſe that divide the hoof, contradiſtinguiſhed from the velarmine, or thoſe that do not divide the hoof. Linnæus has, with an accuracy peculiar to himſelf, defined thoſe neceſſary diſtinctions of ſpecification in his method of claſſification.

BALANCE, or BALLANCE, is one of the ſix ſimple powers in mechanics, principally uſed in determining the equality or difference of weights in heavy bodies, and conſequently their maſſes or or quantities of matter.

The Deceitful BALANCE, or that which cheats by the inequality of its brachia, is founded on the ſame principle as the ſteel-yard.

Aſſay BALANCE, is a very nice balance uſed in docimaſtical operations, to determine exactly the weight of minute bodies.

The ſtructure of the aſſayer's ſcale is little different from that of common ſcales, otherwiſe than by its nicety and ſmallneſs. The longer the beam of it is, the more exact may the weight of a body be found; however, 10 or 12 inches are a ſufficient length.

Hydroſtatic BALANCE, is an inſtrument contrived to determine accurately the ſpecific gravity of both ſolid and fluid bodies.

BALANCE *of Trade*, ſignifies that which is commonly meant by comparing the importing of foreign commodities with the exporting of the native. And it is reckoned that that nation has the advantage in the balance of trade, which exports more of the native commodities, and imports leſs of the foreign.

The reaſon aſſigned is, that if the native commodities be of a greater value than are exported, the balance of that account muſt be made up in bullion or money; and the nation grows ſo much richer, as the balance of that account amounts to.

BALANCE *of a Clock* or *Watch*, is that part which regulates the beats.

BALANCE *Fiſh*, in ichthyology, ſignifies a ſpecies of ſqualus or ſhark.

BALANCING among ſeamen, implies the contracting a ſail into a narrower compaſs, in a ſtorm, by retrenching, or folding up a part of it at one corner: this method is uſed in contradiſtinction to reefing, which is common to all the principal ſails; but balancing is peculiar to few, ſuch as the mizen of a ſhip, and the main ſail of thoſe veſſels in which it is extended by a boom.

The balance of the mizen is thus performed: the mizen yard is lowered a little, then a ſmall portion of the ſail is rolled up at the peek or upper corner, and faſtened to the yard about one-fifth inward from the outer end or yard arm towards the maſt.

A boom main ſail is balanced, after all its reefs are taken in, by rolling up a ſimilar portion of the hindmoſt or aftmoſt lower corner called the clue, and faſtening it ſtrongly to the boom.

BALANUS, in zoology, is the trivial name of a ſpecies of lepas.

BALANUS, myrepſica, or oily acorn, in pharmacy, ſignifies a nut of a purging quality, and the dry preſſing or powder, after the oil is taken out, is of a cleanſing and drying nature.

BALAUSTINE, Baulauſtia, or Balauſtia, in medicine, denote the flowers of the wild pomgranate. They are rough to the taſte, but very aſtringent, and are therefore uſed in diærrheas, and other fluxes.

BALBUSARDUS, in ornithology, is a ſynonyme of a ſpecies of the bald buzzard and falco genus, in the firſt order of birds.

BALCONY, in architecture, a projecture in the front of a houſe, or other building, ſupported by pillars or conſoles, and encompaſſed with a baluſtrade.

BALDACHIN, or BALDAQUIN, in architecture, ſignifies a building in the form of a canopy, ſupported by pillars, and frequently uſed as a covering to inſulated altars. The term baldachin, alſo is uſed for the ſhell over the door.

BALDMONIE, in botany, is a ſynonymous term for the Gentian root uſed in the materia medica. It is uſed alſo to expreſs a ſpecies of ginger called radamata.

BALDNESS, ſignifies a defect of hair. Among the cauſes of it immoderate venery is reputed one of the chief; yet this opinion is in many caſes erroneous; old age uſually brings it on of courſe. Some anatomiſts ſay the proximate cauſe of baldneſs ariſes from the dryneſs of the brain, and its ſhrinking from the cranium; it having been obſerved, that in bald perſons there is always a vacuity or empty ſpace between the ſkull and the brain.

BALE, in commerce, denotes thoſe kinds of goods that are packed up in cloth, and corded round very tight, in order to keep them from breaking, or preſerve them from the weather.

A bale of cotton yarn is from 300 to 400 weight; of raw ſilk, is from 100 to 400; of lockram or, dowlas, either three, three and a half, or four pieces.

BALE *Goods*, ſignify, among the Engliſh merchants, ſuch goods as are imported or exported in bales; but the French give that name to hardware, and other ſorts of merchandize, which come to Paris, and are commonly made by bad workmen of indifferent materials.

BALISTES, or old wife fiſh, in ichthyology, is a genus of fiſhes belonging to the order of nantes, and fourth claſs of animal nature. The characters are theſe: the head is flat; there are eight teeth in each ſide, and the two anterior ones are longeſt, in the place of gills, the baliſtes has an aperture immediately above the pectoral fins; the body is flat, the ſcales are joined together by the ſkin, and the belly is keeled. There are eight ſpecies, viz.

1. The monoceros, or unicorn fiſh, whoſe head fin conſiſts of but one ray, and the tail rays are carinated. They moſtly frequent thoſe ſeas that ſurround the Bahama iſlands, where the corals are in greateſt plenty.

2. The hiſpidus, whoſe head fin is uniradiated, and there is a round black ſpot in the tail fin. The body is rough, and briſtly towards the tail. The ſpine or horn is ſituated between the eyes; the ſnout is ſubulated; and inſtead of a belly fin, it has a jagged ſharp ſpine. This ſpecies is a native of Carolina.

3. The tomentoſus, whoſe head fin is biradiated, and the body of it towards the hind part is hairy. It is a native of America.

4. The papilloſus, has a biradiated back fin, and a papillous body.

5. The verrucoſus, has a triradiated back fin; and the tail is full of little warts. In the place of a belly fin, this ſpecies has a large, thick, warty ray. It has 25 ſmall reverſed ſharp ſpines at the ſide of the tail, diſpoſed in four rows. It is a native of India.

6. The aculeatus has a triradicated back fin; and the ſpines of the tail lean upon each other. It is alſo a native of India.

7. The vetula, or old wife, has a triradiated back fin; the belly fin is longitudinal, and ſomewhat carinated; and the tail fin is forked. It is found at Aſcenſion iſland.

8. The ringens, has a triradicated back fin; there are three folds on each ſide of the head, and the tail fin is forked. This ſpecies is likewiſe found at Aſcenſion iſland.

BALIVO Amovendo, in law, was anciently a writ for removing a bailiff from his office, for want of having ſufficient land in his bailiwick to anſwer the king and his people, according to the ſtatute of Weſtminſter, 2 Reg. Orig. 78.

BALK, among builders, generally implies red deal, it alſo denotes the ſummer beam of a houſe; or the poles and rafters, which ſupport the roofs of barns, &c.

BALKS, in agriculture, ſignify the diviſions left in fields to aſcertain mounds of different proprietors.

It alſo ſpecifies the ridges or banks between two furrows or pieces of arable lands.

Balks, among ſhip builders, denote the framing of that part of the hulk, which includes the hold or holt.

Balks, in the menage, are thoſe huts which are raiſed on purpoſe to conceal a fowler near the haunt of game, who ply at lakes in hard froſt for their food. The menageriſt has a ſpy loft, and a conductor to level his piece upon. Formerly they were much uſed, but now are little practiſed, as the modes to ſurmount the difficulty of obtaining the game is the beſt part of the fowler's paſtime.

BALKERS, in the Britiſh fiſhery, denote perſons placed on rocks, and eminences at ſea, to ſpy the herring droves, and give notice to the fiſhermen, by waving boughs, what way they go, and where they may be found.

BALL, in a general ſenſe, indicates a ſpherical or round body, whether natural or artificial.

Ball, in the military art, comprehends all ſorts of bullets for firearms, from the ſize of the cannon to that of the piſtol. Cannon balls are of iron; muſket balls, piſtol balls, &c. are of lead. The experiment has been tried of iron balls for piſtols and fuſees; but they are juſtly rejected, not only on account of their lightneſs, which prevent them from flying in a ſtraight direction, but becauſe they are apt to furrow the barrel.

Ball *of a Pendulum*, is the weight at the bottom. In ſhorter pendulums, it is called the bob.

Ball, in pyrotechnics, or fire works, is a compoſition of various combuſtible ingredients, ſerving to burn, ſmoke, give light, &c. In this ſenſe are comprehended fire balls, light balls, ſmoke balls, ſtink balls, ſky balls, water balls, land balls, &c. &c.

Ball, among the Corniſh miners, ſignifies a tin mine.

Ball, among printers, is a kind of wooden tunnel ſtuffed with wool, contained in a leather cover, which is nailed to the wood, with which the ink is applied on the forms to be wrought off.

Horse *Balls*, among farriers, are given to horſes medicinally, and are of an oval ſhape, not exceeding the ſize of a pullet's egg; and ſhould be dipped in ſweet oil to make them ſlip down the eaſier. Some horſes have a ſtrait gullet, which makes them very averſe to a ball being thruſt down their throats; ſuch horſes had better have drenches given them, or their medicines may be mixed with bran, or in their maſhes.

Ball *Vein*, in mineralogy, is a name given by the miners of Suſſex to a ſort of iron ore, common there, and wrought to conſiderable advantage. It yields not any great quantity of metal, but what it has runs freely in the fire; it is uſually found in looſe maſſes, not in the form of a ſtratum, and is often covered with one or more cruſts. It generally contains ſome ſparkling particles; and is uſually of a circular form in the perfect maſſes, thickeſt in the middle, and gradually thinner as it approaches the ſides.

Ball *and Socket*, is an inſtrument made of braſs, with a perpetual ſcrew, ſo as to move horizontally, vertically, and obliquely; and is generally uſed for the managing of ſurveying and aſtronimical inſtruments.

Puff Ball, the Engliſh name of the lycoperdon.

Martial Balls, in pharmacy, are a mixture of filings of iron and cream of tartar, formed into a ſolid conſiſtence and form of a ball, which is uſed to impregnate water or other liquids with iron diſſolved by the tartareous acid.

Mercurial Balls, in pharmacy, are an amalgamation of mercury and tin, ſufficiently ſolid to be moulded, and to preſerve a given form. The method of making them is by adding mercury to melted tin, and pouring the fluid maſs into a round hollow mould. Theſe balls are employed to purify water, in which they are boiled.

Balls *of Silk Worms and Spiders*, are little caſes or cones of ſilk, in which thoſe inſects depoſit their eggs. Spiders are extremely careful of their balls, which they carry about with them, adhering to the papillæ about their anus. Grew mentions balls or bags of a ſpecies of ſilk worms in Virginia, as big as hens eggs, and containing each four aurelias.

Balls *in Electricity*, are two pieces of cork, or pith of elder, nicely turned in a lathe to the ſize of a ſmall pea, and ſuſpended by fine linen threads; intended as electrometers, and of excellent uſe to diſcover ſmall degrees of electricity, to obſerve the changes of it from poſitive to negative, and *vice verſa*; and to eſtimate the force of a ſhock before the diſcharge, ſo that the operator ſhould always be able to tell very nearly before the diſcharge, by knowing how high he has charged his jars, what the exploſion will be.

Fire Balls, are bags of canvas filled with gun-powder, ſulphur, ſalt-petre, pitch, &c. to be thrown by the ſoldiers, or out of mortars, in order to fire the houſes, incommoding trenches, advanced poſts, or the like.

Light Balls, in pyrotechny, are ſuch as diffuſe an intenſe light around; after having been caſt out of the hand or a mortar, and burn for ſome time, and illuminate the adjacent parts.

Smoke or Dark Balls, are thoſe which fill the air with ſmoke, and darken a place to prevent diſcoveries. To prepare a darkening ball, make an oval or ſpherical bag, melt roſin over the coals, and add an equal part of ſalt petre not purified, alſo of ſulphur, and a fifth part of charcoal. The whole being well incorporated, put in tow firſt ſhred, and fill the bags with this compoſition, and dip it after the ſame manner as a fire ball.

Stink Balls, are thoſe which yield a great ſtench where fired to annoy the enemy. Their preparation is thus: Melt ten pounds of pitch, ſix of roſin, twenty of ſalt petre, eight of gunpowder, and four of colophony; to theſe add two of charcoal, ſix of horſehoofs cut ſmall, three of aſſa-fœtida, one of ſtinking ſaracen, and any other offenſive ingredients. The reſt as in the former.

Sky Balls, are thoſe caſt on high out of mortars, and which, when arrived at their height, burſting like rockets, afford a ſpectacle of decoration. Sky balls are made of a wooden ſhell, filled with various compoſitions, particularly that of the ſtars of rockets. Theſe are ſometimes intermixed with crackers and other combuſtibles, making rains of fire, &c.

Water Balls, are thoſe which ſwim and burn a conſiderable time in the water, and at length burſt in it. Theſe are made in a wooden ſhell, the cavity of which is filled with refined ſalt petre, ſulphur, ſaw-duſt boiled in water of ſalt petre, and dried; to which ſometimes other ingredients are added, as iron filings, Greek pitch, amber duſt, powdered glaſs, and camphor. The ingredients are to be ground, mixed up, and moiſtened with linſeed oil, nut oil, olive oil, hemp-ſeed oil, or petrol. At the bottom is placed an iron coffin, filled with whole gunpowder, that the ball may at laſt burſt with a greater noiſe: and, laſtly, the ball is, by the addition of lead or otherwiſe, made of the ſame ſpecific gravity with water.

Land Balls are thoſe which, being thrown out of a mortar, fall to the ground, burn, and burſt there. The ingredients are much the ſame as in the water balls, only the ſpecific gravity is not attended to.

BALLAD, ſignifies a vulgar ſong, adapted to the capacity of the lower claſs of people.

BALLAST, is a naval term, denoting any heavy matter, as ſtone, gravel, iron, &c. thrown into the hold of a ſhip, in order to make her ſink a proper depth into the water, that ſhe may be capable of carrying a ſufficient quantity of ſail without overſetting

The knowledge of ballaſting a ſhip with propriety, is certainly an article that deſerves the attention of the ſkilful mariner: for although it is known, that ſhips in general will not carry a ſufficient quantity of ſail till they are laden ſo deep that the ſurface of the water will nearly glance on the extreme breadth amidſhips, yet there is more than this general knowledge required; ſince, if ſhe has a great weight of heavy ballaſt, as lead, iron, &c. in the bottom, it will place the centre of gravity too low in the hold; and although this will enable her to carry a great ſail, ſhe will nevertheleſs ſail very heavily, and run the riſk of being diſmaſted by her violent rolling.

To ballaſt a ſhip, properly, is the art of diſpoſing thoſe materials ſo that ſhe may be duly poiſed, and maintain a proper equilibrium on the water, as neither to be too ſtiff nor too crank, qualities equally pernicious: as in the firſt, although the ſhip may be fitted to carry a great ſail, yet her velocity will not be proportionably increaſed; whilſt her maſts are more endangered by her ſudden jerks and exceſſive labouring: and in the laſt, ſhe will be incapable of carrying ſail, without the riſk of overſetting.

The whole art of ballaſting, therefore, conſiſts in placing the centre of gravity to correſpond with the trim and ſhape of the veſſel, ſo as neither to be too high nor yet too low; neither too far forward nor yet too far aft; and to lade the ſhip ſo deep, that the ſurface of the water may nearly riſe to the extreme breadth amidſhips; and thus ſhe will be enabled to carry a good ſail, incline but little, and ply well to the windward.

Ships are ſaid to be in ballaſt when they have no other loading. Maſters of veſſels are obliged to declare the quantity of ballaſt they bear, and to unload it at certain places.

Ship maſters are prohibited to unlade their ballaſt in havens, roads, &c. the neglect of which has ruined many excellent ports. Ships and veſſels taking in ballaſt in the river Thames, are to pay ſo much a tun to the Trinity houſe, Deptford; who employ ballaſtmen, and regulate them; and their lighters to be marked, &c. on pain of 10l.

BALLATOONS, are large heavy luggage-boats uſed for carrying wood by the river from Aſtracan and the Caſpian ſea from Moſcow. Theſe will carry from 100 to 200 ton, and have from 100 to 120 men employed to row and tow them along.

BALLET, **Balet**, or **Baletto**, a kind of dramatic poem, repreſenting ſome notable action or ſubject divided into ſeveral entries; in which ſeveral perſons appear, and recite things under the name of ſome illuſtrious character or fabulous deity.

Ballet is more particularly uſed for a kind of comic dance, conſiſting of a ſeries of ſeveral airs of different kinds of movements, which together repreſent ſome ſubject or action. They are performed chiefly by maſks, repreſenting ſylvans, tritons, nymphs, ſhepherds, and the like; and conſiſt of three parts, the entry, figure, and the retreat.

BALLERUS, in botany, is a trivial name for a ſpecies of the gourd of paleſtine, frequently mentioned in the holy writ.

Ballerus, in ichthyology, is a ſynonyme for the leather mouth, or carcaſſii tertium genus.

The pallerus, blica and pleyſta, are called by this name.

BALLIAGE, or **Bailiage**, in commerce, is a ſmall duty paid to the city of London by aliens, and even denizens, for certain commodities exported by them.

BALISTA was a machine uſed by the ancients for ſhooting darts; it reſembled in ſome meaſure our croſs bow.

BALLOON, or **Ballon**, in a general ſenſe, ſignifies any ſperical hollow body. In chemiſtry a balloon denotes a round ſhort necked veſſel, uſed to receive what is diſtilled by means of fire.

In architecture, a balloon is a round globe on the top of a pillar; and among engineers, a balloon is a kind of bomb made of paſte board, and played off in fire works, either in the air or on the water, in imitation of a real bomb.

Air **Balloon**, is deſcribed in the Syſtem of Aeroſtation.

Balloon alſo denotes a kind of game ſomewhat reſembling tennis. The balloon is played in the open field, with a great round ball of double leather blown up with wind, and thus driven to and fro with the ſtrength of a man's arm, fortified with a brace of wood.

Balloon, or **Balloen**, is more particularly uſed among voyagers for the ſtate barges of Siam. Theſe balloons are a kind of brigantine, managed with oars, of very odd figures, as ſerpents, ſea horſes, &c. but, by their ſharpneſs and number of oars, of incredible ſwiftneſs.

Balloon, in the French Paper trade, is a term which ſignifies a quantity of paper, containing 24 reams.

Balloon, **Ballon**, or **Ballot**, in the French glaſs trade, ſignifies a certain quantity of glaſs plates, ſmaller or greater according to their quality. The ballon of white glaſs contains 25 bundles, of ſix plates per bundle; but the ballon of coloured glaſs is only of 12½ bundles, and of three plates to a bundle.

BALLOTA, white horehound, in botany, is a genus of the gymnoſpermia order, belonging to the didynamia claſs of plants: and in the natural method ranking under the 42d order, Verticillatæ. The calyx has 5 teeth, with 10 ſtriæ; and the upper lip of the corolla is crenated. It is a common weed growing on the ſides of banks in moſt parts of England.

BALLOTADE, in the menage, ſignifies the leap of a horſe between two pillars, or upon a ſtraight line, made with juſtneſs of time, with the aid of the hand and the calves of the legs; and in ſuch a manner, that when his fore-feet are in the air, he ſhows nothing but the ſhoes of his hinder feet without yerking out.

BALLOTING, a methcd of voting at elections, &c. by means of little balls uſually of different colours, by the French called ballots; which are put into a box privately.

BALLUSTARII, or **Ballistes**, in the ancient hiſtory of the military, denotes the ſoldiery who fought with the Balliſta.

But in the modern acceptation of the word, it denotes archus, or croſs-bow-men.

BALLUSTER, in architecture, is a ſmall kind of pillar uſed for balluſtrades.

BALLUSTRADE, is a ſeries or row of balluſters, joined by a rail; ſerving as well for a reſt to the elbows as for a fence or incloſure to balconies, altars, and ſtair caſes.

BALM, in botany, is the ſame as Meliſſa.

Balm, or **Balsam**, is the ſame as Balſam.

Balm *of Gilead*, is the ſame as Amyris.

BALNEARII *Servi*, in antiquity, were ſervants or attendants belonging to the baths. Some were appointed to heat them, called fornicatores; others were denominated capſarii, who kept the cloaths of thoſe that went into them; others aliptæ, whoſe care it was to pull off the hair; others unctuarii, who anointed and perfumed the body.

BALNEARIUS *Fur*, in law, and in antiquity, denoted a kind of thief who practiſed ſtealing the cloaths of perſons in the baths; ſometimes alſo called fur balnearum. The crime of thoſe thieves was a kind of ſacrilege; for the hot baths were ſacred: hence they were more ſeverely puniſhed than common thieves who ſtole out of private houſes. The latter were acquitted with paying double the value of the thing ſtolen; whereas the former were puniſhed with death.

BALNEUM, is a term uſed by chemiſts to ſignify a veſſel filled with ſome matter, as ſand, water, or the like, in which another is placed that requires a more gentle heat than the naked fire.

BALLONICH, is the Eaſtern name for rough, or crude camphor. By this name it was known to the ancients.

BALSAM, or *Native* **Balsam**, is an oily, reſinous, liquid ſubſtance, flowing either ſpontaneouſly, or by means of inciſion, from certain plants.

There are a great variety of balſams, generally denominated from the ſubſtances from which they are obtained.

BALSAMATION, in the records of the literati, implies the art of embalming the dead.

BALSAMELÆON, in pharmacy, denotes the Balſamum judaicum.

BALSAMICS, *Balſamica*, ſignify mitigating; the term balſamic is a very lax one; it includes medicines of very different qualities, as emollients, detergents, reſtorativesr &c. But in medicines of all theſe kinds there ſeems to be this requiſite in them, viz. that they be ſoft, yielding, and adheſive, alſo that by their ſmallneſs they have a ready diſpoſition to motion. Medicines of this tribe are generally required for complaints whoſe ſeat is in the viſcera; and as they cannot be conveyed there but by the common road of the circulation, it follows, that no great effects can be expected from them but by their long continuation. Hoffman calls by the name of balſamics thoſe medicines which are hot and acrid, alſo the natural balſams, gums, &c. by which the vital heat is increaſed.

BALTAGI, among the Turks, ſignify porters, and hewers of wood, in the court of the grand ſignior; who alſo mount on horſeback when the emperor rides out. Part of them muſt be caſtrated in order to keep watch at the gates of the firſt and ſecond courts of the ſeraglio. Theſe laſt are called capigi, and their commander capigi paſcha.

BALTHEUS Orionus, or *Belt of Orion*, in aſtronomy, is a part of the conſtellation Orion, conſiſting of 3 ſtars of the 2d magnitude, placed as it were in Orion's girdle or belt.

BALTIMORA, in botany, is a genus of the polygamia neceſſaria order, belonging to the ſyngeneſia claſs of plants. The receptaculum is chaffy; there is no pappus; the calyx is cylindrical and polyphyllous; and the ray of the corolla is quinqueſtorous. There is but one ſpecies, the recta, a native of Maryland.

BALTIMORE *Bird*, in ornithology, is the ſame as the Oriolus.

BAMBO, in commerce, is a meaſure containing five pints Wincheſter meaſure.

BAMBOE or **Bamboo**, in botany, the trivial name of a ſpecies of arundo.

BAMIER, is the name of a plant common in Egypt. It produces a pyramidal huſk, with ſeveral compartments, of the colour of a lemon, and filled with muſky ſeeds. This huſk dreſſed with meat is a wholeſome food, and has a very agreeable flavour. The Egyptians make great uſe of it in their ragouts.

BAN, in commerce, is a ſort of ſmooth fine muſlin, which the Engliſh import from the Eaſt Indies. The piece is almoſt a yard broad, and runs about 20 yards and a half in length.

BANANA Tree, is a ſpecies of the muſa or plantain.

BANCI Jus, or the privilege of having a bench, was antiently only allowed to the king's judges, *qui ſummam adminiſtrant juſtitiam*. Inferior courts, as courts baron, hundred courts, &c. were not allowed that prerogative; and even at this day the hundred court at Freibridge in Norfolk is held under an oak at Gey-wood; and that of Woolfry, in Herefordſhire, under an oak near Aſhton in that county, called Hundred-oak.

BANCO, is an Italian word, which ſignifies bank. It is commonly uſed to ſignify the bank of Venice.

BAND, in a general ſenſe, denotes ſome ſmall narrow ligament, with which any thing is bound, tied, or faſtened round about.

BAND, in architecture, is a general name for any flat low member, or moulding, that is broad but not very deep.

BAND *of Soldiers*, in military affairs, are thoſe who fight under the ſame flag or enſign.

BAND *of Penſioners*, are a company of 120 gentlemen, who receive a yearly allowance of 100l. for attending on his majeſty on particular occaſions.

BAND is alſo the denomination of a military order in Spain, inſtituted by Alphonſus XI. king of Caſtile, for the younger ſons of the nobility; who, before their admiſſion, muſt ſerve 10 years at leaſt, either in the army or at court; and are bound to take up arms for the Catholic faith againſt Infidels.

BANDAGE, in ſurgery, ſignifies a fillet, roller, or ſwathe, uſed in dreſſing and binding up wounds, reſtraining dangerous hemorrhages, and in joining fractured and diſlocated bones.

BANDALEER, or **BANDELEER**, in military affairs, denotes a large leathern belt, thrown over the right ſhoulder, and hanging under the left arm; worn by the antient muſqueteers both for ſuſtaining their fire arms, and the carriage of their muſket charges, which being put up in little wooden caſes, coated with leather, were hung, to the number of twelve, to each bandaleer.

BANDELET, or **BANDLET**, in architecture, denotes any little band, or flat molding; ſuch as that which crowns the Doric architrave.

BANDERET, a general, or one of the commanders in chief of the forces. This appellation is given to the principal commanders of the troops of the canton of Bern in Switzerland, where there are four banderets, who command all the forces of that canton.

BANDITTI, from the Italian bandito, denominate perſons proſcribed, or outlawed. It is alſo a denomination given to highwaymen or robbers who infeſt the roads in troops, eſpecially in Italy, France, and Sicily.

BANDOLEER CASE, ſignifies the little wooden barrel uſed by the Gallic ſoldiery, to keep their ammunition dry when out on a march in caſe of wet weather. It likewiſe implies a ſmall wooden caſe, containing a ſufficient quantity of powder for the charge of a muſquet.

BANDORE, is the name of a muſical inſtrument with ſtrings, reſembling a lute, and ſaid to be invented in the fourth year of queen Elizabeth, by John Roſe, a citizen of London.

BANDY LEGS, from the French *bander*, to bend, ſignifies a diſtortion of the legs, when they turn either inward or outward on either ſide; ariſing from ſome defect in the birth, or imprudence in the nurſe, endeavouring to make a child ſtand or walk before the legs are ſtrong enough to ſuſtain the weight of the body.

BANE, in a general ſenſe, ſignifies deſtruction or overthrow. Thus, "I will be the bane of ſuch a man," is a common ſaying. So, when a perſon receives a mortal injury by any thing, we ſay, "it was his bane."

BANGLE EARS, in the menage, is an imperfection in a horſe, remedied in the following manner. Place his ears in ſuch a manner as you would have them ſtand; bind them with two little boards ſo faſt that they cannot ſtir, and then clip away all the empty wrinkled ſkin cloſe by the head.

BANGUE, is a ſpecies of opiate, in great uſe throughout the eaſt, is a kind of wild hemp, growing in the countries of the Levant: it differs little, either as to leaf or ſeed, from our hemp, except in ſize.

BANIANS, are a religious ſect in the empire of the Mogul, who believe a metempſychoſis, or tranſmigration of ſouls; and will therefore eat no living creature, nor kill even noxious animals, but endeavour to releaſe them when in the hands of others.

Banians in a proper ſenſe, is reſtrained to a peculiar caſt, or tribe, of Indians, whoſe office or profeſſion is trade and merchandize: in which ſenſe, Banians ſtand contradiſtinguiſhed from Bramins, Cuttery, and Wyſe, the three other caſts into which the Indians are divided.

The four tribes or caſts are abſolutely ſeparate as to occupation, relation, marriage, &c. though all of the ſame religion; which is more properly denominated the religion of the Bramins, who make the eccleſiaſtical tribe, than of the Banians, who make the mercantile. The proper Banians are called, in the ſhaſter, or book of their law, by the name of Shuddery; under which are comprehended all who live after the manner of merchants, or tranſact buſineſs for others, as brothers; excluſive of the mechanics, or artificers, who make another caſt, called Wyſe.

The Banians have no peculiar ſect or religion, unleſs it be, that two of the eight general precepts given by their legiſlator Bremaw to the Indian nation, are, on account of the profeſſion of the Banians, ſuppoſed more immediately to relate to them, viz. thoſe which enjoin veracity in their words and dealings, and avoiding all practices of circumvention in buying and ſelling.

The Banians are the great factors, by whom moſt of the trade of India is managed; in this reſpect, comparable to the Jews and Armenians, and not behind either, in point of ſkill and experience, in whatever relates to commerce. Nothing is bought but this their mediation. They are diſperſed, for this purpoſe, through all parts of Aſia, and abound in Perſia, particularly at Iſpahan and Gombroom, where many of them are extremely rich, yet not above acting as brokers. The chief agents of the Engliſh, Dutch, and French Eaſt India companies, are of this nation: being faithful, they are generally entruſted with the caſh of thoſe companies in their keeping. They act alſo as bankers, and can give bills of exchange for moſt cities in the Eaſt Indies.

Their form of contract in buying and ſelling is remarkable; being done without words, in the profoundeſt ſilence, only by touching each other's fingers: the buyer looſening his pamerin, or girdle, ſpreads it on his knee, and both he and the ſeller having their hands underneath, by the intercourſe of the fingers, mark the price of pounds, ſhillings, &c. demanded, offered, and at length agreed on. When the ſeller takes the buyer's whole hand, it denotes a thouſand; and, as many times as he ſqueezes it, as many thouſand pagods, or roupees, according to the ſpecies in queſtion, are demanded: when he only takes the five fingers, it denotes five hundred; and when only one, one hundred: taking only half a finger, to the ſecond joint, denotes fifty; the ſmall end of the finger, to the firſt joint, ſtands for ten.

BANISHMENT, ſignifies exile, and is of two kinds: viz. the one voluntary, and upon oath; the other by compulſion, for ſome offence or crime. The former properly called abjuration, is now ceaſed; the latter is chiefly enjoined by judgment of Parliament. Yet the outlawing and tranſportation may alſo be conſidered as a ſpecies of exile.

BANISTERIA, in botany, is a genus of the trigynia order, belonging to the decandria claſs of plants; and in the natural method ranking under the 23d order, Trihilatæ. The calyx is quinquepartite, with nectarious pores on the outſide of the baſe; the petals are roundiſh and ungulated; the ſeeds are three, with membranaceous wings. There are ſeven ſpecies, all natives of warm countries, but poſſeſſing no remarkable properties.

BANK, in commerce, ſignifies a common repoſitory, where many perſons agree to keep their money, to be always ready at their call or direction; under certain ſocieties or communities, who take the charge of it, either to improve it, or to keep it ſecure.

The firſt inſtitution of banks was in Italy, where the Lombard Jews kept benches in the market-places for the exchange of money and bills; and *banco* being the Italian name for *bench*, banks took their title from this word.

Banks are of two principal kinds. 1. One ſort is either public, conſiſting of a company of monied men, who being duly eſtabliſhed, and incorporated by the laws of their country, agree to depoſit a conſiderable fund, or joint ſtock, to be employed for the uſe of the ſociety, as lending money upon good ſecurity, buying and ſelling bullion, diſcounting bills of exchange, &c. or private, i. e. ſet up by private perſons, or partnerſhips, who deal in the ſame way as the former upon their own ſingle ſtock and credit.

The greateſt bank of circulation in Europe is the Bank of England. The company of which was incorporated by parliament, in the fifth and ſixth years of king William and queen Mary, by the name of The Governors and Company of the Bank of England; in conſideration of the loan of 1,200,000l. granted to the government; for which the ſubſcribers received nearly 8 per cent.

By this charter, the company are not to borrow under their common ſeal, unleſs by act of parliament; they are not to trade, or ſuffer any perſon in truſt for them to trade, in any goods or merchandize; but they may deal in bills of exchange, in buying or ſelling bullion, and foreign gold and ſilver coin, &c.

By an act of parliament paſſed in the 8th and 9th years of William III. they were impowered to enlarge their capital ſtock to 2,201,171l. 10s. It was then alſo enacted, that bank ſtock ſhould be a perſonal, and not a real eſtate; that no contract either in word or writing, for buying or ſelling bank ſtock, ſhould be good in law, unleſs regiſtered in the books of the bank within 7 days, and the ſtock transferred in 14 days; and that it ſhall be felony, without benefit of clergy, to counterfeit the common ſeal of the bank, or any ſealed bank bill, or any bank note, or to alter or eraſe ſuch bills or notes. By another act paſſed in the 7th of queen Anne, the company were impowered to augment their capital to 4,402,343l. and they then advanced 400,000l. more to the government; and in 1714, they advanced another loan of 1,500,000l.

In the third year of the reign of king George I. the intereſt in their capital ſtock was reduced to 5 per cent. when the bank agreed to deliver up as many exchequer bills as amounted to 2,000,000l. and to accept an annuity of 100,000l. and it was declared lawful for the bank to call from their members, in proportion to their intereſts in the capital ſtock, ſuch ſums of money as in a general court ſhould be found neceſſary. If any member ſhould neglect to pay his ſhare of the moneys ſo called for, at the time appointed by notice in the London Gazette, and fixed upon the Royal Exchange, it ſhould be lawful for the bank, not only to ſtop the dividend of ſuch member, and to apply it towards payment of the money in queſtion, but alſo to ſtop the transfers of the ſhare of ſuch defaulter, and to charge him with an intereſt of 5 per cent. per annum, for the money ſo omitted to be paid: and if the principal and intereſt ſhould be three months unpaid, the bank ſhould then have power to ſell ſo much of the ſtock belonging to the defaulter as would ſatisfy the ſame. After this, the bank reduced the intereſt of 2,000,000l. lent to the government, from 5 to 4 per cent. and purchaſed ſeveral other annuities, which were afterwards redeemed by the government, and the national debt due to the bank reduced to 1,600,000l. But in 1742, the company engaged to ſupply the government with 1,600,000l. at 3 per cent. which is now called the 3 per cent. annuities; ſo that the government was now indebted to the company 3,200,000l. the one half carrying 4, and the other 3 per cent.

In the year 1746, the company agreed that the ſum of 986,800l. due to them in the exchequer bills unſatisfied, on the duties for licences to ſell ſpirituous liquors by retail, ſhould be cancelled, and in lieu of it to accept of an annuity of 39,442l. the intereſt of that ſum at 4 per cent. The company alſo agreed to advance the further ſum of 1,000,000l. into the exchequer, upon the credit of the duties ariſing by the malt and land tax at 4 per cent. for exchequer bills to be iſſued for that purpoſe; in conſideration of which, the company were enabled to augment their capital with 986,800l. the intereſt of which, as well as that of the other annuities, were reduced to 3½ per cent. till the 25th of December 1757, and from that time to carry only 3 per cent.

And in order to enable them to circulate thoſe exchequer bills, they eſtabliſhed what is now called bank circulation. The nature of which may be underſtood from what follows:

The company of the bank are obliged to keep caſh ſufficient not only to anſwer the common, but alſo any extraordinary demand that may be made upon them; and whatever money they have by them, over and above the ſum ſuppoſed neceſſary for the purpoſes, they employ in what may be called the trade of the company; that is to ſay, in diſcounting bills of exchange, in buying of gold and ſilver, and in government ſecurities, &c. But when the bank entered into the abovementioned contract, as they did not keep unemployed a larger ſum of money than what they deemed neceſſary to anſwer their ordinary and extraordinary demands, they could not conveniently take out of their current caſh ſo large a ſum as a million, with which they were obliged to furniſh the government, without either leſſening that ſum they employed in diſcounting, buying gold and ſilver, &c. or inventing ſome method that ſhould anſwer all the purpoſes of keeping the million in caſh. The method which they choſe, and which fully anſwers their end, was as follows:

They opened a ſubſcription, which they renew annually, for a million of money; in which the ſubſcribers advance 10 per cent. and enter into a contract to pay the remainder, or any part of it, whenever the bank ſhall call upon them, under penalty of forfeiting the 10 per cent. ſo advanced; in conſideration of which, the bank pays the ſubſcribers 4 per cent. intereſt for the money paid in, and ¼ per cent. for the whole ſum they agree to furniſh; and in caſe a call ſhall be made upon them for the whole, or any part of it, the bank further agrees to pay them at the rate of 5 per cent. per annum for ſuch ſum till they repay it, which they are under an obligation to do at the end of the year. By this means the bank obtains all the purpoſes of keeping a million of money by them; and though the ſubſcribers, if no call is made upon them (which is in general the caſe) receive 6½ per cent. for the money they advance, yet the company gains the ſum of 23,500l. per annum by the contract; as will appear by the following calculation:

The bank receives from the government for the advance of a million - - - - - -	£. 30,000
The bank pays the ſubſcribers who advance 100,000l. and engage to pay (when called for) 900,000l. more	6,500
The clear gain to the bank therefore is -	23,500

This is the ſtate of the caſe, provided the company ſhould make no call on the ſubſcribers; which they will be very unwilling to do, becauſe it would not only leſſen their profit, but affect the public credit in general.

Bank-ſtock may not improperly be called a trading ſtock, ſince with this they deal very largely in foreign gold and ſilver, in diſcounting bills of exchange, &c. Beſides which, they are allowed by the government very conſiderable ſums annually for the management of the annuities paid at their office. All which advantages render a ſhare in their ſtock very valuable; though it is not equal in value to the Eaſt India ſtock. The company make dividends of the profits half yearly, of which notice is publicly given; when thoſe who have occaſion for their money may readily receive it; but private perſons, if they judge convenient, are permitted to continue their funds, and to have their intereſt added to the principal.

This company is under the direction of a governor, deputy-governor, and 24 directors, who are annually elected by the general court, in the ſame manner as in the Eaſt India company. Thirteen, or more, compoſe a court of directors for managing the affairs of the company. The officers of this company are very numerous.

The ſtability of the bank of England is equal to that of the Britiſh government. All that it has advanced to the public muſt be loſt before its creditors can ſuſtain any loſs. No other banking company in England can be eſtabliſhed by act of parliament, or can conſiſt of more than ſix members. It acts, not only as an ordinary bank, but (as we have already ſeen) as a great engine of ſtate; receiving and paying the greater part of the annuities which are due to the creditors of the public; circulating exchequer bills; and advancing to government the annual amount of the land and malt taxes, which are frequently not paid up till ſome years thereafter. It likewiſe has, upon ſeveral different occaſions, ſupported the credit of the principal houſes, not only in England, but of Hamburgh and Holland. Upon one occaſion it is ſaid to have advanced for this purpoſe, in one week, about 1,600,000l. a great part of it in bullion.

In Scotland there are two public banks, both at Edinburgh. The one is called The Bank of Scotland, which was eſtabliſhed by act of parliament in 1695; the other, called The Royal Bank, by royal charter in 1727.

Within theſe 30 years there have alſo been erected private banking companies in almoſt every conſiderable town, and even in ſome villages in Scotland. Hence the buſineſs of the country is almoſt entirely carried on by paper-currency, i. e. by the notes of thoſe different banking companies; with which purchaſes and payments of all kinds are commonly made. Silver very ſeldom appears, except in the change of a twenty ſhillings bank note, and gold ſtill ſeldomer. It is well known, that the trade of the city of Glaſgow has been doubled in about 15 years after the firſt erection of the banks there; and that the trade of Scotland has been more than quadrupled ſince the firſt erection of the two public banks at Edinburgh.

The value of the ſilver money, which circulated in Scotland before the union in 1707, and which immediately after it was brought into the bank of Scotland, in order to be recoined, amounted to £.411,117 : 10 : 9 ſterling. No account has been got of the gold coin; but it appears from the ancient accounts of the mint of Scotland, that the value of the gold annually coined ſomewhat exceeded that of the ſilver. There were a good many people too upon this occaſion, who, from a diffidence of repayment, did not bring their ſilver into the bank of Scotland; and there was, beſides, ſome Engliſh coin, which was not called in. The whole value of the gold and ſilver, therefore, which circulated in Scotland before the Union, cannot be eſtimated at leſs than a million Sterling. It ſeems to have conſtituted almoſt the whole circulation of that country; for though the circulation of the bank of Scotland which had then no rival, was conſiderable, it ſeems to have made but a very ſmall part of the whole. In the preſent times the whole circulation of Scotland cannot be eſtimated at leſs than two millions, of which that part which conſiſts in gold and ſilver moſt probably does not amount to half a million. But though the circulating gold and ſilver of Scotland have ſuffered ſo great a diminution during this period, its real riches and proſperity do not appear to have ſuffered any. Its agriculture, manufactures, and trade, on the contrary, the annual produce of its land and labour, have evidently been augmented.

It is chiefly diſcounting bills of exchange, that is, by advancing money upon them before they are due, that the greater part of banks and bankers iſſue their promiſſory notes. They deduct always, upon whatever ſum they advance, the legal intereſt till the bill ſhall become due. The payment of the bill, when it becomes due, replaces to the bank the value of what had been advanced, together with a clear profit of the intereſt. The banker, who advances to the merchant whoſe bill he diſcounts, not gold and ſilver, but his own promiſſory notes, has the advantage of being able to diſcount to a greater amount, by the whole value of his promiſſory notes, which he finds by experience are commonly in circulation. He is thereby enabled to make his clear gain of intereſt on ſo much a larger ſum.

The late multiplication of banking companies in both parts of the united kingdom, an event by which many people have been much alarmed, inſtead of diminiſhing, increaſes the ſecurity of the public. It obliges all of them to be more circumſpect in their conduct, and, by not extending their currency beyond its due proportion to their caſh, to guard themſelves againſt thoſe malicious runs which the rivalſhip of ſo many competitors is always ready to bring upon them. It reſtrains the circulation of each particular company within a narrower circle, and reduces their circulating notes into a ſmaller number. By dividing the whole circulation into a greater number of parts, the failure of any one company, an accident, which, in the courſe of things, muſt ſometimes happen, becomes of leſs conſequence to the public.

Since the free trade has been granted to Ireland, a National Bank has been opened in the city of Dublin, under the firm of the Governor and Company of the Bank of Ireland. It is ſaid their capital amounts to upwards of 4 millions. The intereſt of money in that kingdom is 6 per cent. per ann. but their ſterling currency at par is 8⅓ per cent. under the real current coin of Great Britain.

2. The other kind of banks conſiſts of ſuch as are inſtituted

wholly on the public account, and are called Banks of Depoſit; the nature of which not being generally underſtood, the following particular explanation may not be unacceptable.

The currency of great ſtates ſuch as Great Britain and Ireland generally conſiſt of their own coin. Should this currency, therefore, be at any time worn, clipt, or otherwiſe degraded below its ſtandard value, the ſtate by a reformation of its coin can effectually re-eſtabliſh its currency. But the currency of a ſmall ſtate, ſuch as Genoa or Hamburgh, can ſeldom conſiſt altogether in its own coin, but muſt be made up, in a great meaſure, of the coins of all the neighbouring ſtates with which its inhabitants have a continual intercourſe. Such a ſtate, therefore, by reforming its coin, will not always be able to reform its currency. If foreign bills of exchange are paid in this currency, the uncertain value of any ſum, of what is in its own nature ſo uncertain, muſt render the exchange always very much againſt ſuch a ſtate, its currency being in all foreign ſtates, neceſſarily valued even below what is worth. In order to remedy the inconvenience to which this diſadvantageous exchange muſt have ſubjected their merchants, ſuch ſmall ſtates, when they began to attend to the intereſt of trade, have frequently enacted, that foreign bills of exchange of a certain value ſhould be paid, not in common currency, but by an order upon, or by a transfer in the books of, a certain bank, eſtabliſhed upon the credit and under the protection of the ſtate; this bank being always obliged to pay, in good and true money, exactly according to the ſtandard of the ſtate.

The banks of Venice, Genoa, Amſterdam, Hamburgh, and Nuremberg, ſeem to have been all originally eſtabliſhed with this view, though ſome of them may have afterwards been made ſubſervient to other purpoſes. The money of ſuch banks, being better than the common currency of the country, neceſſarily bore an agio, which was greater or ſmaller, according as the currency was ſuppoſed to be more or leſs degraded below the ſtandard of the ſtate. The agio of the bank of Hamburgh, for example, which is ſaid to be commonly about 14 per cent. is the ſuppoſed difference between the good ſtandard money of the ſtate, and the clipt, worn, and diminiſhed currency poured into it from all the neighbouring ſtates.

In order to remedy theſe inconveniences, a bank was eſtabliſhed in 1609, under the guarantee of the city of Amſterdam. The bank received both foreign coin, and the light and worn coin of the country, at its real and intrinſic value in the good ſtandard money of the country, deducting only ſo much as was neceſſary for defraying the expence of coinage, and the other expences of management. For the value which remained after this ſmall deduction was made, it gave a credit in its books. This credit was called bank money; which, as it repreſented money exactly according to the ſtandard of the mint, was always of the ſame real value, and intrinſically worth more than current money. It was at the ſame time enacted, that all bills drawn upon or negociated at Amſterdam of the value of 600 gilders and upwards, ſhould be paid in bank money, which at once took away all uncertainty in the value of thoſe bills. Every merchant, in conſequence of this regulation, was obliged to keep an account with the bank in order to pay his foreign bills of exchange, which neceſſarily occaſioned a certain demand for bank money.

Thoſe depoſits of coin, which the bank was bound to reſtore in coin, conſtituted the original capital of the bank, or the whole value of what was repreſented by what is called bank money. At preſent they are ſuppoſed to conſtitute but a very ſmall part of it. In order to facilitate the trade in bullion, the bank has been for theſe many years in the practice of giving credit in its books upon depoſits of gold and ſilver bullion. This credit is generally about 5 per cent. below the mint price of ſuch bullion. The bank grants at the ſame time what is called a recipice or receipt, intitling the perſon who makes the depoſit, or the bearer, to take out the bullion again at any time within ſix months, upon retransferring to the bank a quantity of bank money equal to that for which credit had been given in its books when the depoſit was made, and upon paying ¼ per cent. for the keeping, if the depoſit was in ſilver, and ½ per cent. if it was in gold; but at the ſame time declaring, that in default of ſuch payment, and upon the expiration of this term, the depoſit ſhould belong to the bank at the price at which it had been received, or for which credit had been given in the transfer books. What is thus paid for the keeping of the depoſit may be conſidered as a ſort of warehouſe rent; and why this warehouſe rent ſhould be ſo much dearer for gold than for ſilver, ſeveral different reaſons have been aſſigned. The fineneſs of gold, it has been ſaid, is more difficult to be aſcertained than that of ſilver. Frauds are more eaſily practiſed, and occaſion a greater loſs in the more precious metal. Silver, beſides, being the ſtandard metal, the ſtate wiſhes to encourage the making of depoſits of ſilver than of thoſe of gold.

The bank of Amſterdam profeſſes to lend out no part of what is depoſited with it, but, for every gilder for which it gives credit in its books, to keep in its repoſitories the value of a gilder, either in money or bullion.

What may be the amount of the treaſure in the bank is a queſtion which has long employed the ſpeculations of the curious. Nothing but conjecture can be offered concerning it. It is generally reckoned, that there are about 2000 people who keep accounts with the bank; and allowing them to have, one with another, the value of 1500l. lying upon their reſpective accounts, the whole quantity of bank money, and conſequently of treaſure in the bank, will amount to 3,000,000l. or, at 11 gilders the pound ſterling, 33,000,000 of gilders; a great ſum, and ſufficient to carry on a very extenſive circulation, but vaſtly below the extravagant ideas which ſome people have formed of this treaſure.

Bank, in the marine, denotes an elevation of the ground or bottom of the ſea, ſo as ſometimes to ſurmount the ſurface of the water, or at leaſt to leave the water ſo ſhallow as uſually not to allow a veſſel to remain a-float over it. In this ſenſe, bank amounts to much the ſame as flat, ſhoal, &c.

BANKER, ſignifies a perſon who traffics and negociates in money, and receives and remits money from place to place by commiſſion from correſpondents, or by means of bills of exchange, letters of credit, &c.

BANKING, in a general ſenſe, implies the making of banks to oppoſe the force of the ſea, rivers, or the like, and ſecure the land from being overflowed. With reſpect to the water which is to be kept out, this is called banking; but with reſpect to the land, which is to be hereby defended, embanking.

Banking is alſo applied to the keeping of a bank, or the employment of a banker. Banking in this ſenſe, ſignifies the trading in money, or remitting it from place to place, by means of bills of exchange. This anſwers to what the French call *faire la banque.*

In France, every body is allowed to bank, whether merchant or not; even foreigners are indulged in this kind of traffic.

In Italy, banking does not derogate from nobility, eſpecially in the republic ſtates; whence it is, that moſt of the younger ſons of great families engage in it. In reality, it was the nobility of Venice and Genoa, that, for a long time, were the chief bankers of Europe.

BANKRUPT, *bancus ruptus*, in law and trade, ſignifies a breaking or failing in the world.

A bankrupt from the ſeveral deſcriptions given of him in our ſtatute law, may be defined "a trader, who ſecretes himſelf, or does certain other acts tending to defraud his creditors." For the better underſtanding of this article, it will be proper to conſider, 1. Who may become a bankrupt: 2. What acts conſtitute a bankrupt:

1. A bankrupt was formerly conſidered merely in the light of a criminal or offender. But at preſent the laws of bankruptcy are calculated for the benefit of trade, and founded on the principles of humanity as well as juſtice; and to that end they confer ſome privileges, not only on the creditors, but alſo on the bankrupt himſelf. On the creditors; by compelling the bankrupt to give up all his effects to their uſe, without any fraudulent concealment: on the debtor; by exempting him from the rigor of the general law, though in reality he has nothing to ſatisfy the debt; ſo that the law of bankrupts, taking into conſideration the ſudden and unavoidable accidents to which men in trade are liable, has given them the liberty of their perſons, and ſome pecuniary emoluments, upon condition they ſurrender up their whole eſtate to be divided among their creditors.

The laws of England have done wiſely in providing at once againſt the inhumanity of the creditor, who is not ſuffered to confine an honeſt bankrupt after his effects are delivered up; and at the ſame time taking care that all his juſt debts ſhall be paid, ſo far as the effects will extend. But ſtill they are cautious of encouraging prodigality and extravagance by this indulgence to debtors: and therefore they allow the benefit of the laws of bankruptcy to none but actual traders; ſince that ſet of men are, generally ſpeaking, the only perſons liable to accidental loſſes, and to an inability of paying their debts, without any fault of their own.

If perſons in other ſituations of life run in debt without the power of payment, they muſt abide the conſequences of their indiſcretion, even though they meet with ſudden accidents that may reduce their fortunes: for the law holds it to be an unjuſtifiable practice, for any perſon but a trader to encumber himſelf with debts of any conſiderable value. If a gentleman of a liberal profeſſion, at the time of contracting his debts, has a ſufficient fund to pay them, the delay of payment is a ſpecies of diſhoneſty, and a temporary injuſtice to his creditor: and if, at ſuch time, he has not a ſufficient fund, the diſhoneſty and injuſtice is the greater. He cannot therefore murmur, if he ſuffers the puniſhment which he has voluntary drawn upon himſelf. But in mercantile tranſactions the caſe is quite otherwiſe. Trade cannot be carried on without mutual credit on both ſides: the contracting of debts is therefore here not only juſtifiable but neceſſary. And if by accidental calamities, as by the loſs of a ſhip in a tempeſt, the failure of brother traders, or by the non-payment of perſons out of trade, a merchant or trader becomes incapable of diſcharging his own debts, it is his misfortune and not his fault. To the misfortunes therefore of debtors, the law has given a compaſſionate remedy, but denied it to their faults: ſince, at the ſame time that it provides for the ſecurity of commerce, by enacting that every conſiderable trader may be declared a bankrupt, for the benefit of his creditors as well as himſelf, it has alſo, to diſcourage extravagance, declared, that no one ſhall be capable of being made a bankrupt, but

but only a trader; nor capable of receiving the full benefit of the ſtatutes, but only an induſtrious trader.

In the interpretation of the ſeveral ſtatutes made concerning bankrupts, it hath been held, that buying *only*, or ſelling *only*, will not qualify a man to be a bankrupt; but it muſt be both buying and ſelling, and alſo getting a livelihood by it: as, by exerciſing the calling of a merchant, a grocer, a mercer, or, in one general word, a *chapman*, who is one that buys and ſells any thing. But no handicraft occupation will make a man a regular bankrupt.

2. The acts of bankruptcy are thoſe which render a man a bankrupt; to define them, according to legal authority, it will be neceſſary to conſult the ſtatutes in that caſe made and provided.

1. Departing from the realm, by which a man withdraws himſelf from the juriſdiction and coercion of the law, with an intent to defraud his crediters.

2. Departing from his own houſe, with intent to ſecrete himſelf and avoid his creditors.

3. Keeping in his own houſe, privately (except for juſt and neceſſary cauſe), ſo as not to be ſeen or ſpoken with by his creditors; which is likewiſe conſtrued to be an intention to defraud his creditors, by avoiding the proceſs of the law.

4. Procuring or ſuffering himſelf willingly to be arreſted, or outlawed, or impriſoned, without juſt and lawful cauſe; which is likewiſe deemed an attempt to defraud his creditors.

5. Procuring his money, goods, chattels, and effects, to be attached or ſequeſtrated by any legal proceſs; which is another plain and direct endeavour to diſappoint his creditors of their ſecurity.

6. Making any fraudulent conveyance to a friend, or ſecret truſtee, of his lands, tenements, goods, or chattels; which is an act of the ſame ſuſpicious nature with the laſt.

7. Procuring any protection, not being himſelf privileged by parliament, in order to ſcreen his perſon from arreſts; which alſo is an endeavour to elude the juſtice of the law.

8. Endeavouring, or deſiring, by any petition to the king, or bill exhibited in any of the king's courts againſt any creditors, to compel them to take leſs than their juſt debts; or to procraſtinate the time of payment, originally contracted for; which are an acknowledgment of either his poverty or his knavery.

9. Lying in priſon for two months, or more, upon arreſt or other detention for debt, without finding bail, in order to obtain his liberty.

10. Eſcaping from priſon after an arreſt for a juſt debt of 100l. or upwards.

11. Neglecting to make ſatisfaction for any juſt debt to the amount of 100l. within two months after ſervice of legal proceſs, for ſuch debt, upon any trader having privilege of parliament.

Theſe are the ſeveral acts of bankruptcy expreſsly defined by the ſtatutes relating to this article; which being ſo numerous, and the whole law of bankrupts being an innovation on the common law, our courts of juſtice have been tender of extending or multiplying acts of bankruptcy by any conſtruction or implication. And therefore Sir John Holt held, that a man's removing his goods privately to prevent their being ſeized in execution, was no act of bankruptcy. For the ſtatutes mention only fraudulent gifts to third perſons, and procuring them to be ſeized by ſham proceſs, in order to defraud creditors: but this, though a palpable fraud, yet, falling within neither of thoſe caſes, cannot be adjudged an act of bankruptcy.

It has alſo been determined expreſsly, that a banker's ſtopping or refuſing payment is no act of bankruptcy: for it is not within the deſcription of any of the ſtatutes; and there may be good reaſons for his ſo doing, as ſuſpicion of forgery, and the like: and if, in conſequence of ſuch refuſal, he is arreſted, and puts in bail, ſtill it is no act of bankruptcy; but if he goes to priſon, and lies there two months, then, and not before, is he become a bankrupt.

BANKRUPTCY, in the language of the law, ſignifies a failure in trade which was carried on ſolely by the profeſſion of buying and ſelling, ſo as to live upon the profits of ſuch traffic.

BANKSIA, in botany, is a genus of the monogynia order, belonging to the tetrandia claſs of plants. The amentum is ſcaly, the corolla conſiſts of four petals; the antheræ are in the cavity of the folds, and ſoſſile; the capſule is bivalvular; and the ſeed is ſolitary, and bipartic. There are four ſpecies, the ſerata, integrifolia, eridæ folia, and dentata, all natives of New Holland.

BANN, Ban, or Banns, ſignifies generally a proclamation of any public ſummons or edict, which a thing is commanded or forbidden.

The word banns is particularly uſed in England in publiſhing matrimonial contracts; which is done in the church before marriage, to the end that if any perſons can ſpeak againſt the intention of the parties, either in reſpect of kindred, precontract, or any other juſt cauſe, they may take their exception in time, before the marriage is conſummated: if there is a licence for the marriage, then this ceremony is omitted; but miniſters muſt not celebrate matrimony between any perſons without a licence, except the banns have been firſt publiſhed three ſeveral times, upon pain of ſuſpenſion, &c.

Bann, is alſo uſed to denote proſcription or baniſhment for a crime proved; becauſe anciently publiſhed by ſound of trumpet; and thoſe who did not appear at the ſummons, were puniſhed by proſcription. Hence, to put a prince under the bann of the empire, is to declare him diveſted of all his dignities.

Bann alſo denotes a pecuniary mulct, or penalty, laid on a delinquent for offending againſt a public ordonance.

Epiſcopal Bann, ſignifies a mulct paid to the biſhop by thoſe guilty of ſacrilege and other crimes.

Bann, is alſo uſed for a ſolemn anathema, or excommunication, attended with curſes, &c. In this ſenſe we read of papal banns, &c.

Bann, in military or naval affairs, denotes a proclamation made in the fleet or army by beat of drum, ſound of trumpet, &c. requiring the ſtrict obſervance of diſcipline, either for the declaring a new officer, or puniſhing an offender.

BANNER denotes either a ſquare flag, or the principal ſtandard belonging to a prince.

The Banner *of France*, was the largeſt and richeſt of all the flags borne by the ancient kings in their great military expeditions. St. Martin's cap was in uſe 600 years as the banner of France; it was made of taffety, painted with the image of that ſaint, and laid one or two days on his tomb to prepare it for uſe.

About the year 1100 came in a more pompous apparatus. The banner royal was faſtened to the top of a maſt, or ſome tall tree, planted on a ſcaffold, borne on a carriage drawn by oxen, covered with velvet houſings, decorated with devices or cyphers of the reigning prince. At the foot of the tree was a prieſt, who ſaid maſs early every morning. Ten knights mounted guard on the ſcaffold night and day, and as many trumpets at the foot of the tree never ceaſed flouriſhing, to animate the troops. This cumberſome machine, the mode of which was brought from Italy, continued in uſe 130 years. Its poſt was in the centre of the army. And here it was that the cheaf feats were performed, to carry off and defend the royal banner; for there was no victory without it, nor was any army reputed vanquiſhed till they had loſt the banner.

BANNERETS, were an ancient order of knights, or feudal lords; who, poſſeſſing ſeveral large fees, led their vaſſals to battle under their own flag or banner, when ſummoned thereto by the king.

Formerly there were two kinds of knights, the firſt were called bannerets and the ſecond bachelors; the firſt compoſed the upper, the ſecond the middle, nobility.

The banneret was a dignitary allowed to march under his own flag, but the bachelarius eques followed that of another. To be qualified as a banneret, one muſt be a gentleman of family, and be able to raiſe a certain number of armed men, with eſtate enough to ſubſiſt at leaſt 28 or 30 men. This expence muſt have been very conſiderable in thoſe days; as each man, beſides his ſervant, had two horſemen to wait on him armed, the one with a croſs-bow, the other with a bow and hatchet. As he was not allowed to be a baron who had not above 13 knights fees, ſo he was not admitted to be a banneret if he had leſs than 10.

Bannerets were ſecond to none but knights of the garter. They were reputed the next degree below the nobility; and were allowed to bear arms with ſupporters, which none elſe may under the degree of a baron. In France, it is ſaid, the dignity was hereditary; but in England it died with the perſon that gained it. The order dwindled on the inſtitution of barronets by king James I. and at length became extinct. The laſt perſon created banneret was Sir John Smith, made ſo after Edghill-fight, for reſcuing the ſtandard of king Charles I.

The form of the banneret's creation was this. On a day of battle, the candidate preſented this flag to the king or general; who, cutting off the train or ſkirt of it, and making it a ſquare, returned it again, the proper banner of bannerets; who are hence ſometimes called knights of the ſquare flag.

Banneret was alſo the name of an officer or magiſtrate of Rome towards the cloſe of the 14th century. The people of that city, and throughout the territory of the church, during the diſputes of the antipopes, had formed a kind of republican government; where the whole power was lodged in the hands of a magiſtrate called ſenator, and twelve heads of quarters called bannerets.

BANNOCK, is a Scotch word, which ſignifies a kind of oaten-cake; baked in the embers, or on a ſtone placed before the fire, generally called a ſconn. It is common in the Northern parts of this kingdom.

BANNUM, in law, ſignifies the utmoſt bounds of a manor or town land, uſually called mears and mounds.

BANOY, in ornythology, ſignifies a ſpecies of the ſparrow hawk, of the genus of falco, and claſs or order the firſt. It is a native of the Philippine iſlands.

BANQUET, is a feaſt or entertainment where people regale themſelves with agreeable food and pleaſant fruits.

Banquet, in the menage, is that ſmall part of the branch of a bridle that is under the eye; which being rounded like a ſmall rod, gathers and joins the extremities of the bit to the branch in ſuch a manner that the banquet is not ſeen, but covered by the cope, or that part of the bit that is next the branch.

BANQUET *Line*, is an imaginary line drawn, in making a bit, along the banquet, and prolonged up or down, to adjuſt the deſigned force or weakneſs of the branch, in order to make it ſtiff or eaſy in curbing.

BANQUET, or *Banquette*, in fortification, is a little foot-bank, or elevation of earth, forming a path which runs along the inſide of a parapet, upon which the muſketeers get up, in order to diſcover the counterſcarp, or to fire on the enemy, in the moat or in the covert-way; but more uſually to obſerve the motions of the enemy.

BANQUETING *Room*, or *Houſe*, was a ſmall ſaloon where the ancient Romans ſupped; but, in after-times, magnificent ſaloons, or banqueting rooms, were built, for the more commodious and ſplendid entertainment of their gueſts.

BANSTICLE, in ichthyology, is a ſpecies of the gaſteroſteus, commonly called the prickle back, of which this name is a ſynonymous term.

BANTAM *Work*, is a kind of painted or carved work, reſembling that of japan, only more gaudy and lighter.

There are two ſorts of Bantam, as well as of Japan work. As, in the latter, ſome are flat, lying even with the black, and others high and emboſſed; ſo, in bantam work, ſome are flat, and others in-cut, or carved into the wood, as we find in many large ſcreens; with this difference, that the japan artiſts work chiefly in gold and other metals; and thoſe of bantam generally in colours, with a ſmall ſprinkling of gold here and there: for the flat bantam work is done in colours, mixed with gum water, proper for the thing deſigned to be imitated.

The carved, or in cut kind, is thus deſcribed by an ingenious artiſt; viz. 1. The wood is primed with whiting and ſize, ſo often, till the primer lie near a quarter of an inch thick; then it is water planed, i. e. rubbed with a fine wet cloth, and, ſome time after, rubbed very ſmooth, the blacks laid on, varniſhed up with a good body, and poliſhed well, but with a gentle hand. This done, the deſign is to be traced out with vermilion and gum water, exactly in the manner in which it is intended to be cut; the figures, trees, buildings, &c. in their due proportion: then the graver is applied, with other tools of proper ſhapes, differing according to the workman's fancy: with theſe he cuts deep or ſhallow, as is found convenient, but never deeper than the whiting lies, the wood being never to feel the edge of the inſtrument. Lines, or parts of the black, are ſtill to be left for the draperies, and other out lines, and for the diſtinction of one thing from another; the rule being to cut where the white is, and leave the black untouched.

The carving being finiſhed, then take to the pencil, with which the colours are laid into the cut work; after this, the gold is to be lain in thoſe places which the deſign requires; for which purpoſe, a ſtrong thick gum arabic water is taken and laid with a pencil on the work; and, while this remains wet, leaf gold is cut with a ſharp ſmooth edged knife, in little pieces, ſhaped to the bigneſs and figure of the places where they are to be laid. Theſe being taken up with a little cotton, they daub them with the ſame cloſe to the gum-water, which affords a rich luſtre. The work thus finiſhed, they clear up the black with oil, taking care not to touch the colours.

BAOBAB, is the name given by Proſper Alpinus to the African calabaſh tree, ſince called ADANSONIA.

BAPHE, in antiquity, ſignifies the fine red colour with which the ſcribes illumined their head lines, before the uſe of printing commenced.

BAPTES, in the materia medica of the old pharmacopias, was ſpecies of the foſſil called bitumen, and in dangerous caſes for inward bruiſes. In the modern practice it is leſs eſteemed, as the lower claſs of people adminiſter in its ſtead what is uſually called black ſlate or ſlate coal.

BAPTISM, in matters of religion, ſignifies the ceremony of waſhing; or a ſacrament, by which a perſon is initiated into the Chriſtian church.

The neceſſity of baptiſm to ſalvation, is grounded on thoſe two ſayings of our Saviour: *He that believeth, and is baptized, ſhall be ſaved; and, except a man be born of water and of the ſpirit, he cannot enter into the kingdom of God.*

The receiving baptiſm is not limited to any time, or age of life. In the canon law we find divers injunctions againſt deferring the baptiſm of infants beyond the 37th day, 30th day, and the 9th day; ſome of them under pecuniary forfeitures.

Salmaſius, and Suicerus from him, deliver it as authentic hiſtory, that for the two firſt ages, no one received baptiſm, who was not firſt inſtructed in the faith and doctrine of Chriſt, ſo as to be able to anſwer for himſelf, that he believed; becauſe of thoſe words, *He that believeth, and is baptiſed*; which, in effect, is to ſay, that no infant, for the firſt two ages, was ever admitted to Chriſtian baptiſm. But, afterwards, they own, that pædo baptiſm came in, upon the opinion that baptiſm was neceſſary to ſalvation. But Voſſius, Dr. Forbes, Dr. Hammond, Mr. Walker, and eſpecially Mr. Wall, who has exactly conſidered the teſtimony and authority of almoſt every ancient writer that has ſaid any thing upon this ſubject, endeavour to evince, that infants were baptiſed even in the apoſtolical age.

It is certain, Tertullian pleads ſtrongly againſt giving baptiſm to infants; which ſhows, at leaſt, that there was ſome ſuch practice in his age, though he diſapproved of it.

It is certain, the ordinary ſubjects of this ſacrament in the firſt ages were converts from Judaiſm and Gentiliſm, who, before they could be admitted to baptiſm, were obliged to ſpend ſome time in the ſtate of catechumens, to qualify them to make their profeſſions of faith, and a Chriſtian life, in their own perſons; for, without ſuch perſonal profeſſions, there were ordinarily no admiſſion of them to the privilege of baptiſm. Thoſe baptiſed in their ſick beds were called clinici; and were held in ſome reproach, as not being reputed true Chriſtians. Hence ſeveral cenſures, in councils and eccleſiaſtical writers, of clinic baptiſm. This clinic baptiſm was not ſufficient to qualify the perſon, in caſe of recovery, for ordination. Some had their baptiſm put off by way of puniſhment when they fell into groſs and ſcandalous crimes, which were to be expiated by a longer courſe of diſcipline and repentance. This was ſometimes 5, 10, 20 years, or more; even all their lives, to the hour of death, when their crimes were very flagrant.

In the earlieſt ages of the church, there was no ſtated time or place for the reception of baptiſm. Afterwards, Eaſter, Whitſuntide, and Epiphany, became ſolemn ſeaſons, out of which baptiſm was not adminiſtered, except in caſes of neceſſity.

In the ancient church, the perſon to be baptized, if an adult was firſt examined by the biſhop or officiating prieſt, who put ſome queſtions to him; as, firſt, Whether he abjured the devil and al his works; ſecondly, Whether he gave a firm aſſent to all the articles of the Chriſtian faith: to both which he anſwered in the affirmative. If the perſon to be baptized was an infant, theſe interrogatories were anſwered by his *ſponſores*, or godfathers. Whether the uſe of the ſponſors was as old as the apoſtles days, is uncertain: perhaps it was not, ſince Juſtin Martyr, ſpeaking of the method and form of baptiſm, ſays not a word of them. In performing the ceremony of baptiſm, the uſual cuſtom was to immerſe the whole body. Thus St. Barnabas, deſcribing a baptized perſon, ſays, "We go down into the water full of ſin and filth, but we aſcend bearing fruit in our hearts."

From this cuſtom the feaſt of Pentecoſt, which was one of the annual ſeaſons of baptiſm, came to be called Whitſunday, i. e. White-ſunday. This garment was afterwards laid up in the church, that it might be an evidence againſt ſuch perſons as violated or denied that faith which they had owned in baptiſm. When the baptiſm was performed, the perſon baptized, according to Juſtin Martyr, "was received into the number of the faithful, who "then ſent up their public prayers to God, for all men, for them"ſelves, and for thoſe who had been baptized."

The ordinary miniſters, who had the right of adminiſtering this ſacrament, that is, of applying the water to the body, and pronouncing the formula, were preſbyters or biſhops; though on extraordinary occaſions, laymen were admitted to perform the ſame.

As to the preſent mode of adminiſtering baptiſm, the church of Rome uſes the following form. When a child is to be baptized, the perſons who bring it wait for the prieſt at the door of the church, who comes thither in his ſurplice and purple ſtole, attended by his clerk. He begins with queſtioning the godfathers, whether they promiſe, in the child's name, to live and die in the true catholic and apoſtolic faith, and what name they would give the child. Then follows an exhortation to the ſponſors; after which the prieſt, calling the child by its name, aſks it as follows: *What doſt thou demand of the church?* The godfather anſwers, *Eternal life.* The prieſt goes on: *If you are deſirous of obtaining eternal life, keep God's commandments, thou ſhalt love the Lord thy God*, &c. This ſaid, he makes the ſign of the croſs on the child's forehead and breaſt, ſaying, *Receive the ſign of the croſs on thy forehead, and in thy heart.* Then taking off his cap, he repeats a ſhort prayer; and laying his hand gently on the child's head, repeats a ſecond prayer: which ended, he bleſſes ſome ſalt; and putting a little of it into the child's mouth, pronounces theſe words, *Receive the ſalt of wiſdom.* All this is performed at the church door. The prieſt, with the godfathers and godmothers, coming into the church, and advancing towards the font, repeat the apoſtles creed and the Lord's prayer. Being come to the font, the prieſt taking a little of his own ſpittle, with the thumb of his right hand, rubs it on the child's ears and noſtrils, repeating, as he touches the right ear, *Ephata, be thou opened.* Laſtly, they pull off its ſwaddling cloaths, or ſtrip it below the ſhoulders, during which the prieſt prepares the oils, &c. The ſponſors then hold the child directly over the font, obſerving to turn it due eaſt and weſt: upon which the prieſt aſks the child, *Whether he renounces the devil and all his works*; and the godfather having anſwered in the affirmative, the prieſt anoints the child between the ſhoulders in the form of a croſs. Then taking ſome of the conſecrated water, he pours part of it thrice on the child's head, at each perfuſion calling on one of the perſons of the Holy Trinity. The prieſt concludes the ceremony of baptiſm with an exhortation. But baptiſm is never refuſed by the canons of this church, to be performed at the dwelling of the child's parents.

The Greek church differs from the Romiſh, as to the rite of baptiſm, chiefly, in performing it by immerſion, or plunging the infant all over in the water.

The forms of adminiſtering baptiſm among us is too well known to require a particular deſcription. They are ſet forth at large in the book of Common Prayer.

By the ancient laws, baptiſm was not to be conferred on image-makers, ſtage players, gladiators, aurigæ, or public drivers, magicians, or even ſtrolling beggars, till they quitted ſuch profeſſions. Slaves were not allowed the privilege of baptiſm without the teſtimony and conſent of their maſters; excepting the ſlaves of Jews, Heathens, and heretics, who were not only admitted to baptiſm, but, in conſequence thereof, had their freedom. Voſſius has a learned and elaborate work *De Baptiſmo*, wherein he accurately diſcuſſes all the queſtions concerning baptiſm according to the doctrine of the ancients.

Hypothetical Baptism was formerly adminiſtered in doubtful caſes, with this formula: *If thou art baptized, I do not rebaptize; if thou art not, I baptize thee in the name of the Father, &c.* This ſort of baptiſm, enjoined by ſome ancient conſtitutions of the Engliſh church, is now fallen into diſuſe.

Solemn Baptism was conferred at ſtated ſeaſons; ſuch in the ancient church, were the Paſchal baptiſm, and that at Whitſuntide. This is ſometimes alſo called general baptiſm.

Lay Baptism has been permitted by both the Common-prayer books of king Edward and that of queen Elizabeth, when an infant is in immediate danger of death, and a lawful miniſter cannot be had. This was founded upon the miſtaken notion of the impoſſibility of ſalvation without the ſacrament of baptiſm: but afterwards, when they came to have clearer notions of the ſacraments, it was unanimouſly reſolved in a convocation, held in the year 1575, that even private baptiſm, in a caſe of neceſſity, was only to be adminiſtered by a lawful miniſter.

Baptism is alſo applied, abuſively, to certain ceremonies uſed in giving names to things inanimate. The firſt notice we have of this cuſtom is in the capitulars of Charles the Great, where it is only mentioned to be cenſured: but, afterwards, it crept into the Roman offices by degrees. Baronius carries its antiquity no higher than the year 968, when the greateſt bell of the church of Lateran was chriſtened by Pope John III. At laſt it grew to that ſuperſtitious height, as to be thought proper to be complained of in the Centum Gravamina of the German nation, drawn up in the public diet of the empire held at Nurimberg anno 1581; where (after having deſcribed the ceremony of baptizing a bell, with godfathers, who make reſponſes as in baptiſm, and gave it a name, and clothe it with a new garment as Chriſtians were uſed to be clothed, and all this to make it capable of driving away tempeſts and devils) they conclude againſt it, as not only a ſuperſtitious practice, but contrary to the Chriſtian religion, and a mere ſeduction of ſimple people.

Baptism, in the ſea language, was formerly and ſtill continues as a ceremony in long voyages on board merchant ſhips, to be practiſed both on perſons and veſſels who paſs the tropic or line for the firſt time.

The baptizing the veſſel is ſimple, and conſiſts only in waſhing them throughout with ſea-water; that of the paſſengers is more myſterious. The oldeſt of the crew, that has paſt the tropic or line, comes with his face blacked, a groteſque cap on his head, and ſome ſea-book in his hand, followed by the reſt of the ſeamen, dreſſed like himſelf, each having ſome kitchen utenſil in his hand, with drums beating; he places himſelf on a ſeat on the deck, at the foot of the main maſt. At the tribunal of this mock magiſtrate, each paſſenger not yet initiated, ſwears he will take care the ſame ceremony be obſerved, whenever he is in the like circumſtances: then, by giving a little money by way of gratification, he is diſcharged, with a little ſprinkling of water; otherwiſe he is heartily drenched with ſtreams of water poured upon him; and the ſhip-boys are incloſed in a cage, and ducked at diſcretion. The ſeamen, on the baptizing a ſhip, pretend to a right of cutting off the beak-head, unleſs redeemed by the captain.

BAPTISMAL, implies ſomething belongingto baptiſm; thus we ſay baptiſmal vow, preſents, &c.

Baptismal *Vow*, or *Covenant*, is a profeſſion of obedience to the laws of Chriſt, which perſons in the ancient church made before baptiſm. It was an indiſpenſable part of the obligation on catechumens, before they were admitted to the ceremony of regeneration.

Baptismal *Preſents*, are ſtill in uſe in Germany, and made by the ſponſors to the infant, conſiſting of money, plate, and ſometimes fieſs of lands; which by the laws of the country are to be kept for the child till of age, the parents having only the truſt, not the right, of diſpoſing of them.

BAPTISTS, in eccleſiaſtical hiſtory, from βαπτιζω, *I baptize*; are a denomination of Chriſtians, diſtinguiſhed from the eſtabliſhed church of England, by their particular opinions reſpecting the mode and the ſubjects of baptiſm.

Inſtead of adminiſtering the ordinance by ſprinkling of water, they maintain that it ought to be adminiſtered only by immerſion. Such, they inſiſt, is the meaning of the word βαπτιζω; ſo that a command to baptize, is a command to immerſe. Thus it was underſtood by thoſe who firſt adminiſtered it. John the Baptiſt, and the apoſtles of Chriſt, adminiſtered it in Jordan and other rivers, and places where there was much water. Both the adminiſtrators and the ſubjects are deſcribed as going down into, and coming up again out of, the water; and the baptized are ſaid to be buried in baptiſm, and to be raiſed again: which language could not, they hold, be properly abopted on ſuppoſition of the ordinance being adminiſtered in any other manner than by immerſion. And thus they affirm it was in general adminiſtered in the primitive church; and is now adminiſtered in the Ruſſian or Greek church: and thus it is, at this day, directed to be adminiſtered in the church of England, to all who are thought capable of ſubmitting to it in this manner.

With regard to the ſubjects of baptiſm, the baptiſts hold that this ordinance ought not at all to be adminiſtered to children or infants, nor to grown up perſons in general; but to adults only of a certain character and deſcription. Our Saviour's commiſſion to his apoſtles, by which Chriſtian baptiſm was inſtituted, is to go and teach all nations, baptizing them: that is, ſay they, not to baptize all they meet with; but firſt to inſtruct them; to teach all nations, or to preach the goſpel to every creature; and whoever receives it, him to baptize in the name of the Father, and of the Son, and of the Holy Ghoſt. To ſuch perſons, and to ſuch only, baptiſm appears to have been adminiſtered by the apoſtles, and the immediate diſciples of Chriſt. They are deſcribed as repenting of their ſins, as believing in Chriſt, and as having gladly received the word. Without theſe qualifications, Peter acquaints thoſe who were converted by his ſermon, that he could not have admitted them to baptiſm. Philip holds the ſame language in his diſcourſe with the eunuch; and Paul treats Lydia, the jailor, and others, in the ſame manner.

Indeed, without theſe qualifications, Chriſtians in general think it wrong to admit perſons to the Lord's ſupper; and, for the ſame reaſons, without theſe qualifications, at leaſt a profeſſion of them, the baptiſts think it wrong to admit any to baptiſm.

The baptiſts in England form one of the denominations of Proteſtant diſſenters. They ſeparate from the eſtabliſhment for the ſame reaſons as their brethren of the other denominations do; and from additional motives derived from their particular tenets reſpecting baptiſm. The conſtitution of their churches, and their modes of worſhip, are congregational or independent: in the exerciſe of which they are protected, in common with other diſſenters, by the act of toleration.

They bore a conſiderable ſhare in the perſecutions of the laſt and of the preceding centuries; and, as it ſhould ſeem, in thoſe of ſome centuries before; for there were ſeveral among the Lollards and the followers of Wickliff, who diſapproved of infant-baptiſm. There were many of this perſuaſion among the Proteſtants and Reformers abroad. In Holland, Germany, and the North, they went by the names of Anabaptiſts and Mennonites; and, in Piedmont and the South, they were found among the Albigenſes and Waldenſes.

The baptiſts ſubſiſt under two denominations, viz. the Particular or Calviniſtical, and the General or Arminian.

BAPTISTERY, in the eccleſiaſtical ceremonial, ſignifies a place in which the Sacrament of baptiſm is performed.

In the ancient church it was one of the exedræ or buildings diſtinct from the church itſelf: and conſiſted of a porch or antiroom where the perſons to be baptized made their confeſſion of faith, and an inner room where the ceremony of baptiſm was performed.

The ancient baptiſteries were commonly called Φωτιστηρια, *photiſteria*, q. d. places of illumination; an appellation ſometimes given to baptiſm.

The name baptiſtery is ſometimes alſo given to a kind of chapel in a large church, which ſerved for the ſame office. It is an obſervation of ſome learned men, that anciently there was but one baptiſtery in a city, and that at the biſhop's church; and that afterwards they were ſet up in pariſh churches, with the ſpecial allowance of the biſhop. They were aboliſhed in the 6th century, and the ceremony was performed in the porch of the church, and in the 8th century removed into the body of the church itſelf.

BAR, in a general ſenſe, denotes a ſlender piece of wood or iron, for keeping things cloſe, or ſecure from falling down.

Bar, in courts of juſtice, is an incloſure made with a ſtrong partition of timber, where the council are placed to plead cauſes. It is alſo applied to the benches where the lawyers or advocates are ſeated, becauſe anciently there was a bar to ſeparate the pleaders from the attorneys and others. Hence our lawyers who are called to the bar, or licenſed to plead, are termed barriſters, an appellation equivalent to licentiate in other countries.

Bar, or Barr, in common law, is a plea or peremptory exception of a defendant, ſufficient to deſtroy the plaintiff's action: and is divided into 1. Bar to common intendment; 2. Bar ſpecial; 3. Bar temporary, and 4. Bar perpetual.

Bar to a common intendment is an ordinary or general bar, which uſually diſables the declaration of the plaintiff; Bar ſpecial is that which is more than ordinary, and falls upon ſome ſpecial circumſtance of the caſe. Bar temporary is ſuch a bar as is good for the preſent, but may afterwards fail; and Bar perpetual is that which overthrows the action of the plaintiff for ever from a trial at law on the merits of the premiſes.

Bar, in heraldry, is an ordinary in the form of the feſs, but much leſs.

Bar, in the menage, is the higheſt part of that place of a horſe's mouth ſituated between the grinders and tuſhes, ſo that the part of the mouth which lies under and at the ſide of the bars retains the name of the gum. A horſe with ſenſible bars has a fine light mouth, with an even and firm appui.

To Bar *a Vein*, in farriery, is an operation performed upon the veins of the legs of a horſe and other parts, with intent to ſtop the malignant humours. It is performed by opening the ſkin above it, diſengaging it, and tying it both above and below, and ſtriking between the two ligatures.

Bar, in muſic, is a ſingle ſtroke drawn perpendicularly acroſs the five lines of a piece of muſic, including between each two a certain quantity or meaſure of time, which is various as the time of the muſic is either triple or common. In common time, between each two bars is included the meaſure of four crotchets; in triple, three. The principal uſe of bars is to regulate the beating of time in a concert. The double bar, is ſet to divide the different airs or tunes one from another, and when two dots are added to each ſide, it ſignifies the foregoing part muſt be played twice over.

Bar, in hydrography, denotes a bank of ſand, or other matter, by which the mouth of a river is in a manner choaked up.

The term *bar* is alſo uſed for a reef of rocks which run acroſs the mouth of an harbour, ſo as to give but a narrow paſſage through a gap, that always requires the flow of a tide to bring in a ſhip. The word alſo implies a ſtrong beam, wherewith the entrance of a harbour is ſecured: this is more commonly called *boom*.

Bar of a tavern or coffee-houſe, is the place where the waiters attend to anſwer the calls of the cuſtomers.

Bar, among printers, denotes a piece of iron with a wooden handle, by which the ſcrew of the preſs is turned in printing.

Bars *of Iron*, are made of the metal of the ſows and pigs when they come from the furnace. Theſe paſs through two forges called the *finery* and the *chauſery*; where, undergoing five ſeveral heats, they are formed into bars.

BARA, is the name of a feſtival celebrated with much magnificence at Meſſina, and repreſenting the aſſumption of the Virgin.

BARABINZIANS, are a tribe of Tartars, living on both ſides of the river Iris. They ſeem to derive their name from the Barabaian deſart, whoſe lakes ſupply them abundantly with fiſh, on which and the produce of their cattle they chiefly ſubſiſt. They have plenty of game and wild-fowl of every kind, particularly ducks and puffins. Moſt of them are heathens, but Mahometaniſm daily gains ground among them. Some of them pay tribute to the Empreſs of Ruſſia, and others to the Khan Taiſha.

BARACK, is the ſame as Barrack, under which article it is deſcribed.

BARALIPTON, among logicians, is a term denoting the firſt indirect mode of the firſt figure of ſyllogiſm. A ſyllogiſm in baralipton, is when the two firſt propoſitions are general, and the third particular, the middle term being the ſubject in the firſt propoſition, and the predicate in the ſecond. The following is of this kind:

Ba. Every evil ought to be feared;
ra. Every violent paſſion is an evil;
lip. Therefore ſomething that ought to be feared is a violent paſſion.

BARALLOTS, in church hiſtory, were a ſect of heretics at Bologna in Italy, who had all things in common, even their wives and children. Their facility in complying with all manner of debauchery made them get the name *obedientes*, compliers.

BARANGI, were officers among the Greeks of the lower empire. Cujas calls them in Latin *protectores*, and others give them the name of *ſecurigeri*. It was their buſineſs to keep the keys of the city gates, where the emperor reſided.

BARATHRUM, in antiquity, was a deep dark pit at Athens, into which condemned perſons were caſt headlong. It had ſharp ſpikes at the top, that no man might eſcape out; and others at the bottom, to pierce and torment ſuch as were caſt in. Its depth and capacioufneſs made it to be applied proverbially to a covetous perſon: a glutton, or a proſtitute.

BARATRY, is the ſame as Baretry, under which article it is explained.

BARATZ, denote letters patent granted by the Turkiſh emperors to the Greek patriarch, biſhops, &c. for the exerciſe of their eccleſiaſtical functions. This Baratz gives the biſhops full power and authority to eſtabliſh and depoſe the inferior clergy, and all other religious perſons; to grant licences for marriages, and iſſue out divorces; to collect the revenues belonging to the churches; to receive the pious legacies bequeathed to them; in ſhort, to enjoy all the privileges and advantages belonging to their high ſtation: and all this (as it is expreſſed in the baratz itſelf) "according to the vain and idle ceremonies of the Chriſtians."

BARB, or Barbe, in the menage, ſignifies a horſe brought from Barbary.

BARBA, in botany, is a ſpecies of pubes, or down, with which the ſurface of ſome plants is covered. The term was invented by Linnæus; and by its application in the ſpecies plantarum, ſignifies a tuſt or bunch of ſtrong hairs terminating the leaves. Meſembryanthemum barbatum, furniſhes an example.

The word is alſo uſed in compoſition to form the trivial names of ſeveral plants, as barba jovis, barba capræ, &c.

BARBACAN, or Barbican, in fortification, denotes an outer defence to a city or caſtle, uſed eſpecially as a fence to the city or walls; alſo, an aperture made in the wall of a fortreſs, to fire through upon the enemy.

Barbacan, alſo denotes a fort at the entrance of a bridge, or the outlet of a city, having a double wall with towers of defence and obſervation.

BARBADOES Tar, in natural hiſtory, is a mineral fluid of the nature of the thicker fluid bitumens, of a nauſeous bitteriſh taſte, very ſtrong and diſagreeable ſmell, found in many parts of America trickling down the ſides of the mountains, and ſometimes floating on the ſurface of the waters. It has been greatly recommended in coughs, and other diſorders of the breaſt and lungs.

BARBARA, among logicians, is the firſt mode of the firſt figure of ſyllogiſms. A ſyllogiſm in barbara is one of which all the propoſitions are univerſal and affirmative; the middle term being the ſubject of the firſt propoſition, and attribute in the ſecond.

Examp. Bar. Every wicked man is miſerable;
Ba. All tyrants are wicked men;
Ra. Therefore all tyrants are miſerable.

BARBARIAN, was a name given by the ancient Greeks and Romans to all who were not of their own country, or were not initiated in their language, manners and cuſtoms. In this ſenſe, the word ſignified with them no more than a foreigner; not ſignifying, as among us, a wild, rude, or uncivilized perſon.

BARBARISM, in a general ſenſe, indicates a rudeneſs of language or behaviour.

Barbarism, in grammar, is an offence againſt the purity of language; an ungrammatical way of ſpeaking or writing, contrary to the true idiom of any particular language, and is ſynonimous with ſoleciſm, which in the modern acceptation of the refined ſtile is the better mode of expreſſion, as the former carries a vulgarity with it, but the latter betokens a knowledge of letters.

BARBATULA, in ichthyology, is a ſpecies of cobitis.

BARBUTUS, in ichthyology, is a ſpecies of the ſilucus.

BARBILLONS, in entomology, ſignify certain bodies uſually two in number, placed under the head of an inſect, and moveable at pleaſure.

BARCALON, is an appellation given to the prime miniſter of the king of Siam. This officer has under his controul every thing relative to commerce both foreign and domeſtic. He is likewiſe ſuperintendant of the king's magazines.

BARCONE, in naval language, ſignifies the craft uſed as coaſters in the Mediterranean.

BARD, in the culinary art, ſignifies a ſlice of ſalted fleſh laid over hollow fuel deſigned for roaſting.

BARDANA, in botany, is the ſame as burdock, which is generally called arctium.

BARDED, in heraldry, ſignifies a horſe fully capariſoned.

BARDELLE, in the menage, ſignifies a ſaddle of wood, frequently denominated ſtraddles.

BARDESANISTS, in philoſophizing, imply the adherents of Barſanes, the chief of the Oriental philoſophy. The whole of their opinions amounted to no more, than that all good works, as well as thoughts, proceeded from a direct influx of the Deity on the ſoul of man; and all evil in a direct contraſt from the devil.

BARDS, in Engliſh, Iriſh, Scotch, and Gallic hiſtory, denote thoſe poets who, in former times, deſcribed and ſung in verſe, the heroic actions of generals and ſtateſmen, with a deſign to recommend and inculcate virtue.

Thoſe bards or bardi were alſo compoſers of love elegies, ſongs of peace, odes of harmony, and nuptual rejoicings.

BARGAIN, in law, ſignifies a contract made between the buyer and ſeller of either goods or chattels, the former is called the bargainee, and the latter the bargainer: it is underſtood, that both are amenable to the terms of ſuch contract, if legally entered into, or in default thereof to abide the conſequence at law, as a breach of commercial faith.

Bargain and Sale, in conveyancing, is a kind of real contract, by which the bargainer for ſome pecuniary conſideration bargains and ſells, i. e. contracts to convey his lands or other things to the bargainee; and becomes by ſuch bargain a truſtee for, or ſeized to the uſe of, the bargainee; and then the ſtatute of uſes completes the purchaſe: or, as it has been well expreſſed by Blackſtone, the bargain firſt veſts the uſe, and then the ſtatute veſts the poſſeſſion.

But as it was foreſeen that conveyances thus made would want all thoſe benefits of notoriety, which the old common law aſſurances were not calculated to give: to prevent therefore clandeſtine conveyances of freeholds, it was enacted in the ſame ſeſſion of parliament, by Stat. 27. Hen. 8. c. 16, that ſuch bargains and ſales ſhould not enure to paſs a freehold, unleſs the ſame be made by indenture, and enrolled within ſix months after, in the county court, or in one of the courts of record at Weſtminſter. In the ſyſtem of Engliſh law, under the Article Conveyancing by Leaſe and Releaſe, this will be further explained.

BARGE, in maritime language, ſignifies a large pleaſure boat of ſtate, equipped with a band of rowers, and decorated with flags and ſtreamers. They are generally uſed for proceſſions on the water, by noblemen, officers of ſtate, or magiſtrates of cities.

Barge is alſo the name of a flat bottomed lighter, uſually employed to load or unload ſhips in harbour.

Barge *Couples*, in architecture, ſignify two beams mortiſed into each other, to ſtrengthen the building.

Barge *Courſe*, in building, ſignifies the projection of tiles over the ends of the rafters.

BARGHMASTER, Barmer, or Barmaster, in the royal mines, ſignifies the ſteward or judge of the barmote. He keeps two great courts yearly, and a ſmall one every week.

BARGEMOTE, or Barmote, is a court which takes cognizance of cauſes and diſputes between miners.

BARILLA, in commerce, is a ſort of aſhes produced from ſea weeds, in the Levant, and much uſed by bleachers and glaſsmakers.

BARING *of Trees*, in agriculture, ſignifies the taking away of ſome of the earth from the roots, ſo as to permit the rain and ſnow to enter at the roots.

BARK, in medicine, ſignifies the rind of the cinchona, or quinquina.

Bark, in botanical language, ſignifies the outer rind or ſkin of trees, which have a cruſted coat.

BARLERIA, or ſnapdragon, in botany, is a genus of the angioſpermia order, belonging to the didynamia claſs of plants.

The flower is uſually of the lip kind, of one leaf, funnel ſhaped, and divided into five parts at the top; four ſlender ſtamina; an oval germen placed in the center; with two roundiſh cells, containing two compreſſed ſeeds. There are four ſpecies, all exotics.

BARLEY, in botany, is a gramineous frumentaceous herb, whoſe qualities are well known in agriculture and huſbandry.

BAUM, among bakers, is the ſame as yeaſt, of which it is a ſynonyme.

BARNACLE, in ornithology, is a ſpecies of the anas.

BAROMETER, in pneumatics, is an inſtrument for meaſuring the weight of the atmoſphere, and is uſually denominated a weather-glaſs; under which article it will be explained.

BARON, is a degree below a viſcount, and is the loweſt title of nobility.

Baron *by Tenure*, is one who holds certain territories of the king, who ſtill retained the tenure in chief to himſelf.

Baron and Feme, in the Engliſh law, is a term uſed for huſband and wife, in relation to each other, and are deemed but one perſon, ſo that a wife cannot be witneſs for or againſt her huſband, *et vice verſa*, except in caſes of high treaſon.

BARONET, is a modern degree of honour inſtituted by James I. on the 22d of May 1611, and made hereditary in the male line.

BARONS *of the Exchequer*, are four judges to whom the adminiſtration of juſtice is committed, in cauſes between the king and his ſubjects, relating to matters concerning the revenue. They were formerly barons of the realm, but of late are choſen from the barriſters at law.

BARONY, ſignifies the honour and territory which gives title to a baron, whether he be a layman or a biſhop.

BARRACKS, in military matters, ſignify the houſes built as public lodgings for the ſoldiery.

BARRATOR, in law, ſignifies a perſon guilty of barretry.

BARRENNESS, is the ſame as ſterility.

BARRETRY, in law, ſignifies the ſtirring up of feuds or quarrels between his Majeſty's liege ſubjects.

BARRICADE, or Barricado, in military affairs, ſignifies the fence raiſed up of earth or rubbiſh, to ſtand proof againſt ſhot.

Barricade, in naval architecture, is a ſtrong rail, which ſupports the quarter deck.

BARRIER, in fortification, is a kind of fence made at a paſſage to ſtop the entry thereof.

BARRISTER, at law, ſignifies a counſellor learned in the law, and admitted to plead at the bar, and there take upon him the defence and protection of his clients.

BARROWS, in Britiſh topography, ſignify thoſe artificial hills, or hillocks, raiſed by the Romans for ſepulchres, as is generally ſuppoſed by our antiquaries.

BARRY, in heraldry, is when the eſcutcheon is divided barways into an even number of partitions, and conſiſts of two or more tinctures interchangeably diſpoſed.

Barry Bendy, in heraldry, is when the eſcutcheon is divided even by both bar and bendways, by lines drawn tranſverſe and diagonally, interchangeably varying the tinctures of which it conſiſts.

Barry Piby, ſignifies when the coat is divided by ſeveral lines drawn obliquely, ſo as to form acute angles.

BASE, in architecture, denotes the lower part of a column.

Base, in fortification, denotes the external ſide of the polygon; or that imaginary line which is drawn from the flanked angle of a baſtion to that which is oppoſite thereto.

Base *of a Figure*, in geometry, denotes the loweſt part of its perimeter.

Base *of a Triangle*, is the loweſt ſide, or that which lies parallel to the horizon.

Base *of a ſolid Figure*, is its loweſt ſide, or that whereon it ſtands.

Base *of a Conic Section*, is a right line in the hyperbola and parabola, formed by the common interſection of the ſecant plane, and the baſe of the cone.

Base *of the Heart*, in anatomy, denotes the broader or upper part of that viſcus, to the ſides of which the two auricles are affixed.

Base, or Basis, in chemiſtry, any body which is diſſolved by another body which it receives and fixes, and with which it forms a compound, may be called the baſis of the compound. Thus, for example, the baſes of neutral ſalts are the alkaline, earthy, and metallic matters, which are ſaturated by the ſeveral acids, and form with them theſe neutral ſalts. It is proper for the conveniency of chemical language to retain this manner of expreſſion; but theſe baſes muſt not be conſidered as inactive, and only yielding to the action of the acids which they fix, and to which they give a body and conſiſtence. In every combination and ſolution, the ſeveral bodies which unite are equally active, their action being reciprocal. They diſſolve each other; ſo that it is as proper to ſay, as Mr. Gellert obſerves, that a metal or an earth diſſolves an acid, as that an acid diſſolves a metal or an earth; though this latter mode of expreſſion is moſt common. Probably the diſſolving power which the more weighty and fixed bodies have, is really much ſtronger than that of bodies leſs weighty and fixed. It certainly is ſo, if the tendency to unite be only the effect of the general attraction, or the gravitation of all particles of matter to each other.

Basis, in pharmacy, is that ingredient on which moſt ſtreſs is laid, for effecting the purpoſe of any compound medicine.

Base, in muſic, is the ſame as Bass.

Base *Fee*, denotes a tenure in fee at the will of the lord. By which it ſtand diſtinguiſhed from ſocage, or free tenure.

Base *Court*, is any court not of record. Such, e. gr. is the court-baron.

Base *Knights, bas chevaliers*, denote the inferior order of knights, as diſtinguiſhed from barons and bannerets, who were the chief or ſuperior knights.

Base *Point*, in heraldry, ſee Point and Eſcutcheon.

Base *Ring of a Cannon*, is the great ring next behind the touch hole.

BASELLA, in botany, climbing night ſhade, from Malabar, a genus of the pentandria order and trigynia claſs. The characters are theſe: the flower hath no empalement; it is ſhaped like a pitcher, cloſed toward the brim; it hath five ſtamina faſtened to the petal, the globular germen, which is ſituated in the centre, ſupports three ſlender ſtyles, crowned by oblong ſtigmas; the petal of the flower remains, and encloſes a roundiſh fleſhy belly, including one round ſeed. There are two ſpecies, all natives of the Indies.

From the berries of the firſt ſort, a beautiful colour is drawn; but when uſed for painting, it does not laſt, but changes to a pale colour; it is probable, however, that ſome method might be found to fix it, as it is ſaid that the juice of theſe berries is uſed for ſtaining callicoes in India.

BASEMENT, in architecture, is a continued baſe, extended a conſiderable length, as around a houſe, a room, or other piece of building.

BASHARIANS, a ſect of Mahometans, being a branch or ſubdiviſion of the Motazalites.

The Baſharians are thoſe who maintain the tenets of Baſhar Ebn Motamer, a principal man among the Motazalites, who varied, in ſome points, from the general tenets of the ſect, as extending man's free agency to a great length, even to the making him independent.

BASHAW, Pascha, or Pacha, is the title of a Turkiſh governor of a province, city, or other diſtrict.

We ſay, the Baſhaw of Babylon, the Baſhaw of Anatolia, the Baſhaw of Bender, &c.

All Egypt is, on the part of the grand ſeignior, governed by a Baſhaw, who has in reality but little power; but ſeems principally to be meant for the means of communicating to his divan of beys, and to the divans of the ſeveral military ogiacs, that is, their bodies, the orders of the grand ſeignior, and to ſee that they be executed by the proper officers.

Baſhaws include beglerbegs, and ſometimes ſangiachegs; though a diſtinction is ſometimes made, and the name Baſhaw is appropriated to the middle ſort or ſuch as have two enſigns or horſe tails carried before them. Thoſe who have the honour of three tails are called beglerbegs, and thoſe who have only one, ſangiachegs.

Baſhaw, uſed abſolutely, denotes the prime vizier; the reſt of the denomination being diſtinguiſhed by the addition of the province, city, or the like, which they have the command of; as the Baſhaw of Egypt, of Paleſtine, &c. The Baſhaws are the emperor's ſpunges. We find loud complaints among Chriſtians of their avarice and extortions. As they buy their governments, every thing is venal with them.

When glutted with wealth, the emperor frequently makes them a preſent of a bow ſtring, and becomes heir to all their ſpoil.

There are alſo ſub baſhaws, or deputy governors under the firſt. Phil. Tranſ. N° 218.

BASHAW, *Captain*, is the title of the Turkiſh high admiral.

BASIATRAHAGI, in botany, is a name uſed by ſome for the common polygonum, or knot graſs.

BASIL, among joiners, denotes the angle to which the edge of an iron tool is ground.

To work on ſoft wood they uſually make their baſil 12 degrees, for hard wood 18; it being obſerved, that the more acute or thin the baſil is, the better and ſmoother it cuts; and the more obtuſe, the ſtronger and better it is for ſervice.

Basil, *Order of St.* is the moſt ancient of all the religious orders; it takes its name from St. Baſil, biſhop of Cæſarea, in Cappadocia, about the middle of the fourth century; who is ſuppoſed to have been the author of the rules obſerved by this order, though ſome diſpute it.

The order of St. Baſil was anciently very famous in the Eaſt, and ſtill continues in Greece. The habit of the monks is black, and plain, conſiſting of a long caſſock, and a great gown with large ſleeves: on their head they wear a hood, which reaches to the ſhoulders: they wear no linen; ſleep without ſheets, in ſtraw; eat no fleſh; faſt often, and till the ground with their own hands.

This order was introduced in the Weſt in 1057, and was reformed in 1579, by pope Gregory XIII. who united the religious of this order in Italy, Spain, and Sicily, into one congregation; of which the monaſtery, of St. Saviour, at Meſſina, is the chief, and enjoys pre-eminence over the reſt. Each community has its particular rule, beſides the rule of St. Baſil, which is very general, and preſcribes little more than the common duties of a Chriſtian life.

Basil, in botany, ocymum, is a genus of the didynamia order and gymnoſpermia claſs of plants, the characters of which are theſe: the empalement of the flower is ſhort, permanent, of one leaf, divided into two lips; the flower is of the lip kind, of one petal inverted; the riſing lip is broad and cut into four obtuſe equal parts; the reflexed lip is long, narrow, and ſawed; it hath four ſtamina on the lower lip, which are reflexed; two of which are a little longer than the other, terminated by half moon-ſhaped ſummits; the germen is divided into four parts, which afterward become four naked ſeeds encloſed in the empalement. There are ſeven ſpecies, all exotics.

Basil, Syrian field Ziziphora, in botany, is a genus of the diandria order and monogynia claſs. The characters are theſe, the flower hath a long, rough cylindrical empalement, which is ſlightly cut into five parts at the brim; and the flower is of the labiated kind, having a long cylindrical tube; the upper lip is oval, reflexed, and entire; and the under lip, or beard, is divided into three equal ſegments, it has two ſpreading ſtamina, terminated by oblong ſummits, and a quadrifid germen, ſupporting a briſtly ſtyle, crowned by a ſharp pointed inflexed ſtigma; the germen turns to four oblong ſeeds, which ripen in the empalement. There are three ſpecies, all natives of the Eaſt.

BASILEUS, is a title aſſumed by the emperors of Conſtantinople, excluſive of all other princes, to whom they give the title rex, king.

The ſame quality was afterwards given by them to the kings of Bulgaria, and to Charlemagne, from the ſucceſſors of which laſt they endeavoured to wreſt it back again.

The title baſileus has been ſince aſſumed by other kings, particularly the kings of England, *Ego Edgar totius Angliæ* baſileus *confirmavi*.

Hence alſo the queen of England was intitled Baſilea and Baſiliſſa.

BASILICA, or **Basilicus**, in anatomy, is the name of a vein, ariſing from the axillary branch, and running the whole length of the arm.

BASILICON, or **Basilicum**, in pharmacy, is the denomination of an officinal unguent or plaſter; called alſo tetrapharmicum, as being compoſed of four ſimples, viz. reſin, wax, pitch, and oil-olive.

BASILICUS, or **Basilica**, in aſtronomy, is the name of a fixed ſtar of the firſt magnitude, in the conſtellation Leo; called alſo Regulus, and Cor Leonis.

BASILIDIANS, in church hiſtory, denotes the followers of Baſilides, an Egyptian, who lived near the beginning of the ſecond century. In general, the Baſilidians, held much the ſame opinion with the Valentinians, another branch of the Gnoſtics.

BASILISC, in amphibiology, is a ſpecies of the Lacerta.

Basilisc is alſo myſtically uſed by the alchemiſts, to denote the ſublimate mercury of the philoſophers.

Basilisc alſo denotes a great piece of ordnance; thus denominated from its reſemblance to the ſuppoſed ſerpent of that name.

The baſiliſc throws an iron ball of two hundred pounds weight. It was much talked of in the time of Solyman emperor of the Turks, in the wars in Hungary; but ſeems now out of uſe.

BASILISCUS, in ornithology, a name given by ſome authors to the regulus criſtatus, or golden crowned wren, which is tranſlated baſiliſc, ſignifies an aſp, as the beſt interpreters agree.

BASIOGLOSSUM, or rather **Basiglossum**, in anatomy, are a pair of muſcles, which ariſe fleſhy from the baſis of the os hyoides, and are inſerted into the root of the tongue: ſerving to draw the tongue towards the bottom of the mouth.

BASIS, in oratory, denotes the fourth member of a complete exordium, being that which ſucceeds the apodoſis, and prepares the way for the propoſition.

BASIUM, among chemiſts, is an extemporaneous tincture of iron and copper, invented by Cloſſæus.

BASKET, a kind of veſſel made of oſier, wicker, ruſhes, or the like, of different figures and ſizes, according to the uſe it is intended for.

Baſkets have their uſes not only in the œconomical, but military affairs; at ſieges, they make uſe of a ſmall baſket filled with earth and ranged on the top of the parapet.

They are about a foot and a half high, as much in diameter at top, and eight or ten inches at bottom; ſo that being ſet together, they leave a ſort of embraſures at the bottom, through which the ſoldiers fire, without expoſing themſelves.

Basket, *Corbeille*, in architecture, a kind of vaſe, or figure-piece of ſculpture, in form of a baſket, filled with flowers or fruits, ſerving to terminate ſome decoration.

Basket *Fiſh*, in ichthiology, is a name given by the Engliſh in North America to a very remarkable fiſh, ſometimes caught in the ſeas thereabout.

Mr. Hooke, to whom it was referred by the Royal Society to name it, has called it *Piſcis echinoſtellaris viſciformis*, the body of it reſembliug an egg-fiſh, or *echinus marinus*, and the arms a ſtar-fiſh, and finally, the dividing of the branches being more like that of the branches of miſletoe than any other natural production we are acquainted with.

This fiſh ſpreads itſelf from a pentagonal mouth piece, or root, in the centre of which the mouth is placed, into five main limbs or branches; and each of theſe, at its firſt iſſuing out of the body, is divided into two, which makes twenty, and ſo on, each dividing to the fourteenth time; at which place they make more than fourſcore thouſand limbs. Theſe are too ſmall to be traced farther by the eye, or preſerved in carriage: but it is very probable that even theſe were again divided, perhaps, ſeveral times.

The branches between the joints are not all equally of a length, though, for the moſt part, they are pretty nearly ſo. The arms or branches are never very ſtrong; but, when they are dry, they are greatly more brittle than before, the leaſt force imaginable deſtroying them.

The ſhoals of Nantucket, an iſland on the coaſt of New England, at times furniſh the fiſhermen with this creature; but it is remarkable, that they are never ſeen there, unleſs when taken by hooks in fiſhing for other fiſh. They claſp the hook bait faſt, and encircle it with all their arms, coming up, when drawn by it, in form of a wicker baſket; whence the name: but, when they have been ſome time out of the water, they become flat.

The uſe of the numerous arms of this fiſh is plainly to catch its prey. It probably extends them to their full length while under the water, and then claſps hold of any thing fit for food that chances to ſwim over them. The fiſhermen have ſometimes found the arms containing ſmall mackrel, or pieces of larger. Phil. Tranſ. N° 57 and 74. It is evident from the deſcription, that this fiſh is of the ſtella abboreſcens, or branched ſtar fiſh kind; but whether the ſame with the commonly known kind, called the caput meduſæ, is not evident from this deſcription. The body of this fiſh, by what is related of its protuberance, and reſemblance to the echini marini, may probably be the aſteropodium, in its foſſil ſtate.

Basket *Salt*, this is a brine ſalt, made from the water of our ſalt ſprings in Cheſhire, and elſewhere, differing from the common brime ſalt in the fineneſs of the grain, and in its whiteneſs and purity.

In the preparing of this kind of ſalt, ſome uſe reſin, and other additions, to break the grain, and make it ſmall: others effect this by keeping up a very briſk fire under it, and ſtirring it all the while; but the moſt approved method is only to take out of this kind the third draught of every pan that is working for the common brine ſalt, and to do this before the granules or cryſtals are perfectly formed. By this means the ſalt is very fine; and when it has been hard preſſed down into ſmall wicker baſkets, it is dried at the ſtove in them, and ſo kept for ſale.

BASON, *Pelvis*, in anatomy, is a round cavity in form of a tunnel, ſituate between the anterior ventricles of the brain, deſcending from its baſe, and ending in the point at the glandula pituitaria.

It is formed of the pia mater, and receives the pituita which comes from the brain, and paſſes through the pituitary gland, and from thence into the veins.

Bason, or **Dish**, among glaſs grinders, who uſe various kinds of baſons, of copper, iron, &c. and of various forms, ſome deeper, others ſhallower, according to the focus of the glaſſes that are to be ground. In theſe baſons it is, that convex glaſſes are formed, as concave ones are formed on ſpheres or bowls. There are two methods of preparing them, viz.

In the firſt, the baſon is fitted to the arbor, or tree of a lath, and the glaſs (fixed with cement to a handle of wood) preſented and held faſt in the right hand within the baſon, while the proper motion is given by the foot of the baſon. In the other the baſon is fixed to a ſtand or block, and the glaſs with its wooden handle moved.

The moveable baſons are very ſmall, ſeldom exceeding five or ſix inches in diameter; the others are larger, ſometimes above ten feet in diameter.

After the glaſs has been ground in the baſon, it is brought ſmoother with greaſe and emery: and poliſhed firſt with tripoli, and finiſhed with paper cemented to the bottom of the baſon.

Bason, among hatters, is a large, round ſhell, or caſe, ordinarily of iron, placed over a furnace; in which the matter of the hat is moulded into form.

The hatters have alſo baſons for the brims of hats, uſually of lead, having an aperture in the middle, of a diameter ſufficient for the largeſt block to go through.

Bason is alſo uſed on various occaſions for a ſmall reſervatory of water.

BASS, in muſic, is that part of the concert which is the moſt heard, which conſiſts of the graveſt, deepeſt, loudeſt, and longeſt ſounds; or which is played on the largeſt pipes or ſtrings of inſtrument.

It is called *baſs*, from the Italian *baſſo*, of the Latin *baſis*, as being the foundation of the harmony.

Muſicians hold the baſs the principal part of a concert, and the foundation of the compoſition; though ſome will have the treble the chief part; which others only make a circumſtance, or ornament.

The ingenious Dr. Franklin, in his very curious letter to lord Kaimes on this ſubject, declares it to be his opinion that the baſs is unneceſſary to ſome tunes, and gives ſome reaſons in ſupport of it, which the curious may ſee there.

Bass, *Counter*, is a ſecond baſs, where there are ſeveral in the ſame concert.

Bass, *Thorough*, is that which proceeds, without interruption, from the beginning of a muſical compoſition to the end. By which it ſtands contradiſtinguiſhed from the ſinging baſs, and the baſſes of violins, which make pauſes from time to time. The thorough-baſs is the harmony made by baſs viols, theorbos, or the like, continuing to play, both while the voices ſing, and the other inſtruments perform their part; and alſo filling the intervals when any of thoſe ſtop.

It is commonly diſtinguiſhed from the other baſſes by figures over the notes, directing what chords are to be played to them; which figures are proper only for the organ, harpſichord, ſpinet, and theorbo lute. But it is to be obſerved a thorough baſs is not always figured, though it ought to be ſo.

Bass, among gardeners, a ſoft kind of ſedge or ruſh, uſed in binding plants, &c.

BASSANUS, in ornithology, is a ſpecies of the Pelican.

BASSE, in ichthyology, is the Engliſh name of the ſea wolf. It is properly a ſpecies of pearch, and is diſtinguiſhed by Artedi by the name of the pearch with thirteen rays in the ſecond fin of the back, and fourteen in the *pinna auri*.

Basse *Cour*, in building, a court ſeparated from the principal one, and deſtined for the ſtables, coach-houſes, and livery ſervants.

Basse *Cour*, of a country ſeat, is the yard or place where the cattle, fowls, &c. are kept.

BASSET, or Basette, a game with cards, ſaid to have been invented by a noble Venetian, for which he was baniſhed. It was firſt introduced into France by ſignior Juſtiniani, ambaſſador of Venice, in 1674. Severe laws were made againſt it by Louis XIV. to elude which they diſguiſed baſſet under the name of *pour & contre*, that is, *for and againſt*, which occaſioned new arrets and prohibitions of parliament. The parties concerned in it are, a dealer or banker, his aſſiſtant, who ſuperviſes the loſing cards, and the punter, or any one who plays againſt the banker.

BASSETING, in the coal mines, denotes the riſe of the vein of coals towards the ſurface of the earth, till it comes within two or three feet of the ſurface.

BASSIA, in botany, is a genus of the dodecandria order, and monogynia claſs of plants.

BASSON, or Bassoon, is a muſical wind inſtrument, blown with a reed, and furniſhed with eleven holes; ſerving for the baſs in concerts of hautboys, &c.

To render it more portable, it divides into two parts, whence it is called a *fagot*. Its diameter at bottom is nine inches, and its holes are ſtopped like thoſe of a large flute.

BASSO Relievo, or Bass Relief, ſignifies a piece of ſculpture, where the figures or images do not protuberate, jet, or ſtand out, far above the plane on which they are formed

Whatever figures or repreſentations are thus cut or ſtampt, ſo that not the entire body, but only a part of it is raiſed above the plane are ſaid to be done in relief: but when it is nearly flat it is called low relief: and when the repreſentation of a perſon is ſtruck on a medal it is uſually ſtiled ſtrong relief.

Basso *Relievos* make part of the furniture of antiquaries. Thoſe of the Trajan and Autonine columns have been copied by Bartoli, and explained by Bellori, &c. Thoſe of the arch of Severus by Suareſius.

Some have alſo made maps of proſpects of countries in baſſo relievo.

BASS Viol, is a muſical inſtrument of the ſame form with that of the violin, except being much larger. It is ſtruck with a bow; and has four ſtrings, and eight ſtops, divided by half ſtops, or ſemi-tones.

The ſound it yields is much more grave, ſweet and agreeable, than that of the violin, and of much nobler effect in a concert.

BASTARD, in law, ſignifies a natural child, or one born out of lawful wedlock.

A baſtard differs from one born in adultery, or inceſt, as the parents of the former are free, or allowed to marry, which thoſe of the latter are not.

The baſtards, or natural ſons of a king in France, are princes when owned; thoſe of a prince, or nobleman, are gentlemen; but thoſe of a gentleman are only plebeians, and pay taxes accordingly.

A baſtard's arms, according to the laws of heraldry, ſhould be croſſed with a bar, fillet or traverſe from the left to the right. They were not formerly allowed to carry the arms of their father, and therefore they invented arms for themſelves, which is ſtill done by the natural ſons of a king.

A baſtard by the laws of England cannot inherit land as heir to his father, being *nullius filius*; nor can any perſon inherit land as heir to him, but one that is heir of his body. If a child be begotten by him who doth marry the woman after the child's birth, yet it is in law a baſtard, though the church holds it legitimate. If a perſon marry a woman, and die before night, and never conſummate marriage, and his wife bring forth a child after, it is yet accounted his child, and legitimate.

If a man or woman marry again, and have iſſue by the ſecond wife or huſband, while the firſt is living, ſuch iſſue is a baſtard in law.

If a woman elope with a ſtranger and have a child by him, her huſband being within the four ſeas, this is ligitimate, and ſhall inherit the huſband's lands. But this is not now adhered to; for though the huſband and wife are both in England, if there be ſufficient proof that he had no acceſs to her, the child will be a baſtard.

By ſtat. 18 Eliz. cap. 3. two juſtices may take order for the puniſhment of the mother and reputed father of a baſtard: and by ſtat. 7 Jac. I. cap. 4. the penalty of commitment to the houſe of correction is inflicted on the woman only. But it ſeems that in both caſes the penalty can only be inflicted, when the child becomes chargeable to the pariſh. By 6 Geo. II. cap. 31. the reputed father may be apprehended by warrant of a juſtice, on the oath of the pregnant woman, and committed, unleſs he gives ſecurity to indemnify the pariſh to which the child belongs. But by ſtat. 18 Eliz. the woman is not compellable to anſwer any queſtions relative to her pregnancy, till one month after her delivery; nor can the man be held to bail, according to ſtatute law, until that period.

Judge Blackſtone, in his commentaries on the laws of England, under the article of public wrongs, has defined baſtardy as a breach of the peace, ſo that doors may be broken in purſuit of the reputed father of a baſtard, who conceals himſelf from the repreſentatives of the pariſh burdened with ſuch ſpurious offspring: yet the ſame excellent law commentator declares, that the perſon ſo concealing himſelf, may uſe fire arms in his defence, and kill thoſe who may break into his apartments. For although the act is a breach of the peace, yet in its nature it is but a debt due from the offender to pariſh, who has his offspring to maintain.

Bastard, in the ſea language, ſignifies a large ſail of galley, which will make way with a ſlack wind.

Bastard is alſo uſed adjectively, or in compoſition with divers other words, to denote things of inferior or diminutive value.

In this ſenſe we meet with baſtard coral, baſtard alabaſter, baſtard amianthus, &c.

BASTARDY, is a defect of birth objected to one born out of wedlock.

BASTERIA, or Allspice, in botany, is a genus of plants not deſcribed by Linnæus. Of this there is but one ſpecies known, which has oval leaves placed oppoſite, flowers coming from the ſides of the ſtalks, and a branched ſhrubby ſtalk. It is a native of Carolina in America. The flowers appear in May, are of a dull purple colour, and have a diſagreeable ſcent. The bark is brown, and has a very ſtrong aromatic flavour, from whence the plants takes the name of Allſpice.

BASTILE, denotes a ſmall antique caſtle, fortified with turrets. Such is the baſtile of Paris, which ſeems the only caſtle that has retained the name: it was begun to be built in 1369, by order of Charles V. and finiſhed in 1383, under the reign of his ſucceſſor.

Its chief occupants are ſtate priſoners.

BASTION, in fortification, ſignifies a huge maſs of earth uſually faced with ſods, ſometimes with brick, rarely with ſtone, ſtanding out from a rampart, of which it is a principal part, and is what in the ancient fortification was called a bulwark.

A baſtion conſiſts of two faces, and two flanks, and an opening towards the centre of the place, called the gorge.

Solid Bastions, are thoſe that are filled up entirely, and have the earth equal to the height of the rampart, without any void ſpace towards the centre.

Void and Hollow Bastions, are thoſe ſurrounded with a rampart and parapet, only ranging round their flanks and faces, ſo as to leave a void ſpace towards the centre; where the ground is ſo low, that if the rampart be taken, no retrenchment can be made in the centre, but what will lie under the fire of the beſieged.

Flat Bastion, is a baſtion built on a right line in the middle of the curtin, when it is too long to be defended by the baſtion at its extremes.

Cut Bastion, is that whoſe point is cut off, and in lieu thereof has a re-entering angle, or an angle inwards with two points outward; this is ſometimes alſo called, baſton with a tenaille; and is uſed either when, without ſuch a contrivance, the angle would be too acute, or when water, or ſome other impediment, hinders the carrying on the baſtion to its full extent.

Compoſed Bastion, is when the two ſides of the interior polygon are very unequal, which makes the gorges alſo unequal.

Regular Bastion, is that which has its due proportion of faces, flanks, and gorges.

Irregular Bastion, is where this proportion and equality is not obſerved.

Deformed Bastion, is where the irregularity of the lines and angles makes the baſtion out of ſhape, as when it wants one of its demi-gorges; one ſide of the interior polygon being too ſhort.

Demi Bastion, is that which hath but one face, and one flank: called alſo an epaulement.

To fortify the angle of a place that is too acute, they cut off the point, and make two demi-baſtions, which form a tenaille, or a re-entering angle. Their chief uſe is before a hornwork, or crownwork.

Double Bastion, is that which on the plane of the great baſtion, has another baſtion, built higher, ſomewhat after the manner of a cavalier; leaving twelve or eighteen feet between the parapet of the lower, and the foot of the higher.

BASTON, in law, ſignifies one of the ſervants to the warden of the Fleet priſon, who attends the king's court with a red ſtaff, for taking ſuch to ward as are committed by the court, and likewiſe attends on ſuch priſoners as are ſuffered to go at large by licence.

Baston, or Batoon, in architecture, denotes a mould in the baſe of a column, otherwiſe called a tore.

Baston, or Batoon, in heraldry, a kind of bend, which does not go from ſide to ſide of the eſcutcheon, as the ſcarf does, but is broken off ſhort, in form of a truncheon.

It is only borne in Engliſh coats of arms as a mark of baſtardy: but French heralds introduce it in arms as a difference, a mark of conſanguinity.

Baston alſo ſignifies the earl marſhal's ſtaff.

BASTONADO, Bastonade, is the puniſhment of beating or drubbing a criminal with a ſtick.

The baſtonade is a puniſhment uſed both among the ancient Greeks, Romans, and Turks.

It is much in uſe in the Eaſt to this day. The method there practiſed is thus: the criminal being laid on his belly, his feet are raiſed, and tied to a ſtake, held faſt by officers for the purpoſe; in which poſture he is beaten by a cudgel on the ſoles of his feet, back, chin, &c. to the number of one or more hundred blows.

BAT, in zoology, a genus of quadrupeds, of the order of Verſpertillio. See Syſtem of Tetrapodology.

Bat, in commerce, is a ſmall baſe ſilver coin, current in divers parts of Germany and Switzerland at different prices.

BATARDIERE, a place in a garden, prepared for the planting of fruit trees in, which being tranſplanted thither from the nurſery, are to be placed in eſpaliers, or elſewhere, to ſupply the place of dead trees.

BATCHELOR's Buttons, in botany, is the ſame as Campion.

BATENKETOS, a ſtar about the third magnitude, in the conſtellation Cetus.

BATFOWLING, a method of catching birds in the night, by lighting ſome ſtraw, or torches, near the place where they are at rooſt: for, upon beating them up they fly to the flames, where, being amazed, they are eaſily caught in nets, or beat down with buſhes fixed to the end of poles, &c.

BATH, Balneum, in medical language, is a convenient receptacle of water for perſons to waſh, or plunge in, either for health or pleaſure.

Baths are either natural or artificial, and are hot or cold.

Hot BATHS, owe their origin partly to the admixture of ſulphureous particles, while the water is paſſing through its ſubterraneous canals, or rather while it creeps through beds and mines of ſulphur, &c. and partly to the fumes and vapours exhaling through the pores of the earth where ſulphur is, either pure or impure, as in coals, amber, &c. Though in moſt hot baths there are likewiſe mixed particles of iron, alum, nitre, and other mineral bodies, which gave them an acid aſtringent taſte.

The chief hot baths in our country are thoſe at Bath and Briſtol, in Somerſetſhire; and thoſe at Buxton and Matlock in Derbyſhire; the latter are rather warm or tepid than hot.

It has been thought by many, that the practice of drinking our Bath waters in Somerſetſhire is not very ancient, and that their ancient uſe was in bathing; but Dr. Friend endeavours to ſhew the internal uſe of thoſe waters to have been very early. Dr. Guidot, in whoſe time this uſage revived, and who has given us the beſt hiſtorical narrative of theſe waters, goes no higher for their internal uſe than the latter end of the ſixteenth century. But they appear to have been in uſe in the thirteenth century: Gilbert, ſurnamed Anglicus, who, according to Bayle, lived in 1210, in the reign of king John, or more probably in that of Edward I. mentions a perſon cured of a leucophlegmacy, attended with a ſwelling, &c. by the ſulphureous Baths; which Dr. Friend underſtands of the Bath waters; and that the cure was wrought by drinking, not bathing, which had been improper in ſuch a caſe.

Dr. Muſgrave makes it probable, that they were reſorted to in the time of Geta; there being ſtill the remains of a ſtatue erected to that general, in gratitude for ſome benefactions which he had conferred on the place. Some pretend that theſe waters were in uſe 800 years before Chriſt. Phil. Tranſ. N° 49. 346.

See the uſes of Bath waters, and their difference from thoſe of Briſtol, under the head Briſtol water.

The Bath waters abound with a mineral ſulphur: they are hot, of a blueiſh colour, and ſtrong ſcent; and ſend forth thin vapours. They do not paſs through the body like moſt other mineral waters; though, if ſalt be added, they purge preſently. On ſettlement they afford a black mud, which is uſed by way of cataplaſms in aches; of more ſervice to ſome than the waters themſelves: the like they depoſit on diſtillation, and no other.

Dr. Aſtendoff found the colour of the ſalt drawn from the king's hot bath to be yellow; and that from the croſs bath, white; whence he concludes, that the croſs bath has more alum and nitre than the hotter, which abounds more with ſulphur; and yet the croſs bath is found to looſen ſhrunk ſinews, by which it ſhould ſeem to abound leſs with alum: it is harſher to the taſte than the others, and ſoaks the hands more. The croſs bath preys on ſilver, and all of them on iron, but none on braſs.
